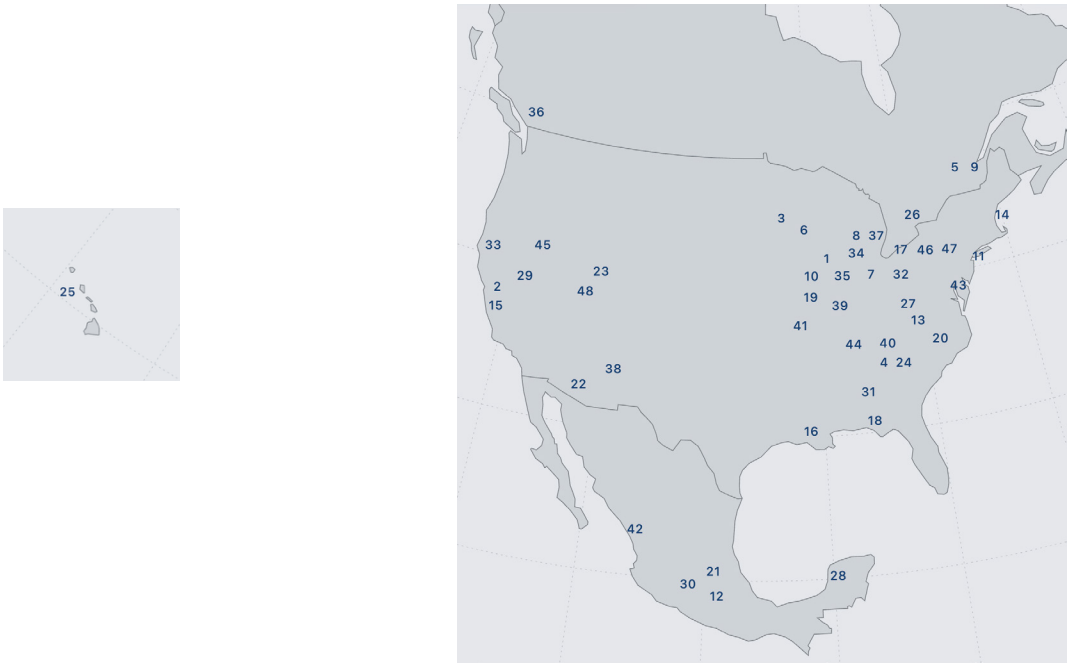
NORTH AMERICAN CHAPTER OF THE INTERNATIONAL GROUP FOR THE PSYCHOLOGY OF MATHEMATICS EDUCATION

PME–NA History and Goals

The International Group for the Psychology of Mathematics Education (IGPME) was founded in 1976 at the Third International Congress on Mathematical Education (ICME-3) in Karlsrühe, Germany, with the first conference held in 1977 in Utrecht in the Netherlands. The North American Chapter of PME (PME-NA) was organized not long after with the first conference held in Evanston, Illinois in 1979. This initial meeting was organized and chaired by Dr. Richard Lesh following the initial National Council of Teachers of Mathematics (NCTM) Research Presession held in 1978 (Boston, Massachusetts). The plenaries at the NCTM meeting (Heinrich Bauersfeld, Efraim Fischbein, & Hans Freudenthal) were instrumental in the founding of IGPME and encouraged Lesh and others to create a North American chapter. The initial meeting in 1979 may have only featured plenary speakers. However, with the second meeting of PME-NA being a joint meeting with IGPME, individual papers published in the conference proceedings became a mainstay of the conference. Early conferences for both IGPME and PME-NA were focused on exploration of various areas of psychology in the teaching and learning of mathematics. Since their origins, PME and PME-NA have expanded and continue to expand beyond their psychologically oriented foundations.

The major goals of the International Group and the North American Chapter are:



1. To promote international contacts and the exchange of scientific information in the psychology of mathematics education;
2. To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of psychologists, mathematicians, and mathematics teachers; and
3. To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

PME–NA Membership

Membership is open to people who are involved in active research consistent with PME-NA's aims or who are professionally interested in the results of such research. Membership is open on an annual basis and depends on payment of dues for the current year. Membership fees for PME-NA (but not PME International) are included in the conference fee each year. If you are unable to attend the conference but want to join or renew your membership, go to the PME-NA website at http://pmena.org. For information about membership in PME, go to http://www.igpme.org and visit the "Membership" page.

2026-2027 PME–NA Steering Committee

Elected Members
Paulo Tan – University of California Santa Cruz (2023-2026)
Verónica Vargas Alejo – University of Guadalajara (2023-2026)
C. Davis (Graduate Student Representative) – Michigan State University (2025-2026)
Uyiosa Ugiagbe (Graduate Student Representative) – University of Georgia (2025-2026)
Olga Fellus (Chair) – Brock University (2024-2027)
Omar Octavio López López – Sociedad Mexicana de Investigación y Divulgación de la Educación Matemática (2024-2027)
Beth MacDonald – Illinois State University (2024-2027)
Ayman Aljarrah – Acadia University (2025-2028)
Sunghwan Byun – North Carolina State University (2025-2028)
Luis Leyva – Vanderbilt University (2025-2028)
Teo Paoletti – University of Delaware (2025-2028)

Appointed Members
Aaron Brakoniecki – Boston University (2017-2026)
Winnie Ko – Indiana State University (2022-2026)

2026 Conference Organizers

Keith Leatham (chair) – Brigham Young University
Blake Peterson – Brigham Young University
Dan Siebert – Brigham Young University
Dawn Teuscher – Brigham Young University

2026 Conference Strand Leaders

Kristen Bieda – Michigan State University
Sunghwan Byun – North Carolina State University
Victoria Delaney – San Diego State University
Erin Krupa – North Carolina State University
Kate Johnson – Brigham Young University
Candace Joswick – University of Texas Arlington
Beth MacDonald – Illinois State University
Allison McCulloch – University of North Carolina Charlotte
Kate Melhuish – Texas State University
Wayne Nirode – Miami University Ohio
Elizabeth Roan – Texas State University
Bima Sapkota – University of Kentucky
Dan Siebert – Brigham Young University
Amber Simpson – Binghamton University
Shari Stockero – Michigan Technological University
Dawn Teuscher – Brigham Young University
Jeremy Zelkowski – University of Alabama
Karen Zwanch – Oklahoma State University

PREFACE

The forty-eighth annual meeting of the International Group for the Psychology of Mathematics Education – North American Chapter was held October 11-14, 2026 on the campus of Brigham Young University in Provo, Utah, USA.

Contributions and Community

As shown in Table 1, 361 proposals were submitted for consideration. Each submitted paper was reviewed by multiple reviewers in a double-blind process. Strand Leaders examined reviewer feedback and made acceptance recommendations as well as for accepted session type. In the end, 93 posters (85% acceptance rate), 123 brief reports (77% acceptance rate), 92 full reports (60% acceptance rate), and 14 working groups / research colloquia (100% acceptance rate) were accepted.

The conference was attended by 217 faculty, 113 students, and 65 virtual registrants. These 395 participants came from the United States, México, Canada, Columbia, Ghana, Hong Kong, and Republic of Korea.

Table 1: Conference Paper Proposal Statistics

Session Type	Submitted	Scheduled	Accepted as is	Rejected	Accepted in some form
Full Research Reports	153	92	92 (60%)	12 (8%)	141 (92%)
Brief Research Reports	116	123	~89 (77%)	15 (13%)	101 (87%)
Posters	78	93	66 (85%)	12 (15%)	66 (85%)
Working Groups	13	13	13 (100%)	0	13 (100%)
Research Colloquia	1	1	1 (100%)	0	1 (100%)
Total	361	322	~261 (72%)	39 (11%)	322 (89%)

Gratitude

We are grateful to every individual who contributed to the success of the conference. The quality of the program is due the efforts of many. Reviewers (n=312) performed a critical scholarly service. Strand Leaders (n=18) assigned reviewers, examined reviews, and made recommendations for acceptance. Past conference chairs, current and past Steering Committee members, and various other colleagues provided insight, feedback, and support that contributed to the program and to the overall experience of the conference community. Many thanks to BYU undergraduates Brooke Francis, Abigail Marchant, and Katelyn Remund, who together copyedited every paper in this proceedings. And finally, thanks to Michael Holmes and his team for helping to organize the conference from beginning to end, and for creating such a wonderful, welcoming environment at the BYU Conference Center.

QUANTITATIVE REASONING AND REDEFINING THE LEARNING-TEACHING-RESEARCH PLAYING FIELD

Kevin C. Moore
University of Georgia
kevin.moore@uga.edu

Since Thompson formalized quantitative reasoning (QR), the field has extensively documented QR's role in student learning but has done comparatively less to develop analogous accounts for teaching. I argue redefining the learning-teaching-research relationship requires grounding teacher development in the "mathematics of students"—models constructed studying student thinking. Drawing on work with teachers and students, I describe how teachers' extant meanings can act as an insufficient foundation for constructing QR-based mathematics of students, and I introduce a perspective for addressing this phenomenon. I extend this discussion by connecting to decentering and arguing it is a cognitive activity teacher educators must determine how to cultivate. Collectively, I call for more attention to what it means to build teaching and teacher education "from the ground up" on the foundation of students' mathematics including their QR.

Keywords: Quantitative Reasoning, Mathematical Knowledge for Teaching, Decentering

Thompson's initial framework on *quantitative reasoning* (*QR*) defined it as, "the analysis of a situation into a quantitative structure—a network of quantities and quantitative relationships" (Thompson, 1989, p. 13). In it, he underscored that readers should interpret the definitions as operational constructs in a system; he intended the definitions support researchers and educators in explaining mathematical ideas and student thinking. Researchers have fittingly extended his theory across the teaching and learning of mathematics at all levels (see Karagöz Akar et al., 2022 for a collection of examples). In doing so, they have identified QR's importance for students' mathematical development while simultaneously identifying the need to understand how to create educational experiences in which students' QR is honored and embraced.

The given directive for this paper was to identify future directions for QR research with respect to this need. I find addressing this directive awkward for three reasons. First, I believe future directions emerge organically. Future directions are not manufactured or created out of thin air. They reveal themselves in the process of doing research and they are realized by pursuing unexpected phenomena. So, look to those surprising or thought-provoking moments within your work for inspiration that opens future directions. Second, novel, unforeseen future directions are often introduced by individuals new to a field. The naivety and inexperience of those entering a field afford a perspective that is simultaneously blind to current research trends and not yet entrenched in a particular viewpoint. So, look to the newer entrants in the field for innovative and unexpected future directions.[1] Third, I consider much of my work to be a derivative of the work produced by those who laid the foundation for QR research. These individuals include Marilyn Carlson, Patrick Thompson, and Les Steffe, to name a few. They created and advised research directions in which I and others found footing. Researchers following their directions have also created new foci requiring additional work. This makes proposing additional future directions seem superfluous. So, look to the founders of QR for

[1] An incomplete list: Hwa Young Lee, Irma Stevens, Claudine Margolis, Amy Smith, Teo Paoletti, Halil Tasova, Kristen Frank, Joseph Antonides, Cameron Byerley, Sara Bagossi, Robert Knurek, Chris Bloom, Allie Olshefke-Clark, Anne Waswa, Yosep Dwi Kristanto, Erin Wood, Jennifer Czocher, Franklin Yu, and Hamilton Hardison.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

productive future directions. Nonetheless, what follows are my musings about areas that need to be fleshed out based on my empirical and classroom work with students and teachers.

Quantitative Reasoning and the Mathematics of Students

Although Thompson is chiefly responsible for the formal theorization of it, QR has origins in the history of human and child experience. Whether it was the Greeks' explorations of incommensurable magnitudes, Egyptians' and Hindus' construction of numeral systems, or Arabians' trigonometric studies, QR served as a tool for humans to organize and problem-solve everyday experiences (Eves, 1990; Thompson, 2011). QR is also an authentic part of children's experiential realities (Piaget, 1952; Piaget & Inhelder, 1974; Steffe, 1991). Accordingly, the specific researcher and educator activities Thompson intended his theory to support are building and using *second-order models of students' mathematics* (Thompson, 2013).

Second-order models of students' mathematics are models researchers build to explain the observable actions of students during mathematical activity (Steffe, 2004; Steffe & Thompson, 2000; Steffe et al., 1983; Thompson & Thompson, 1996; Thompson, 2008, 2013; Thompson & Saldanha, 2000). Steffe and Thompson formalized this construct to acknowledge a researcher only has access to their own mathematical thinking and thus building a viable model of student thinking requires acting in intentional and analytical ways. A researcher remains permanently skeptical as to the possibility of using their own ways of thinking to explain the thinking of a student, and they do this by designing settings in which they intentionally restrain aspects of their own mathematics (Moore et al., in press; Steffe & Thompson, 2000). For instance, a researcher iteratively seeks out unexpected or novel student behavior that breaks their model. That places the researcher in a position to construct new mathematics through the student's actions. The opportunity to construct new mathematics that they can attribute to a student is what makes second-order model building an exciting venture (Steffe & Thompson, 2000).

Because a researcher expects to construct new mathematics when modeling student thinking, second-order models are not to be bound or framed by institutionalized knowledge and learning goals found in common curricula (Steffe & Thompson, 2000). In fact, a researcher constructing second-order models should expect to generate a mathematics that has incompatibilities with long-established learning goals. Learning goals are developed by adults and thus constrained by their mathematics. Second-order models mitigate the incompatibilities existing between adults' and students' mathematics. Second-order models of students' mathematics act as our best proxy for students' mathematics, which are made more viable through iterative research.

Second-order models of students' mathematics are termed *mathematics of students* (Steffe & Thompson, 2000). For the remainder of this paper, I use mathematics of students to refer to second-order models of students' mathematics. I use *QR-based meanings* throughout to refer to mathematics of students that involve QR. The goal for this paper is to discuss pursuing the ideal of teachers teaching in ways sensitive to the mathematics of students. I underscore that when I discuss teachers constructing and leveraging QR-based meanings, the QR-meanings I refer to were co-constructed by researchers and students.

Using Quantitative Reasoning to Further Mathematical Knowledge for Teaching

At the 2005 annual meeting, Mewborn (2005) argued, "By and large, I do not yet see robust frameworks in the areas of mathematics teaching and teacher education that would parallel the frameworks in the area of learning" (p. 6). Her view remains true two decades later. The field has gained knowledge understanding the phenomena of teaching and teacher education. For instance, the introduction of *mathematical knowledge for teaching* (*MKT*) frameworks (e.g., Ball et al.,

2008; Hill et al., 2008; Silverman & Thompson, 2008; Thompson & Thompson, 1996; Thompson, 2016) has established several informative research strands. These frameworks and associated strands, however, are not as robust as their counterparts in learning. The former lack the type of developmental accounts found in the latter (Carlson, Bas-Ader, et al., 2024; Kennedy, 2016; O'Bryan, 2025; Rocha, 2023; Tallman, 2023; Thompson, 2016). Again, Mewborn's (2005) words mostly remain true: "we have predictive frameworks in the area of student learning, but we are still at the stage of explanatory frameworks in the area of teaching" (p. 5).[2]

Developmental accounts of MKT are less prevalent than those of student learning partially due to MKT being a more recent research development. If we assume that developmental accounts of MKT paralleling those of student learning are possible, their construction is imperative. Such accounts will position us to better understand teachers' realities and how to collaborate with them to improve their practice. In what follows I provide two considerations for this pursuit. I begin with a need for developmental accounts that incorporate teachers' extant knowledge in relationship with QR-based meanings. I then center the mathematics of students in MKT development with attention to QR's role in this development.

Extant Meanings and their Foundation for Learning

It is important that an educator consider an individual's extant meanings no matter with whom they are working. For instance, an educator intending to support a student's development of fractional reasoning must give significant attention to the ways in which the student can construct and coordinate units; the operations and meanings a student has available constrains how they conceive of a situation and thus the potential novel operations and meanings they can construct (Hackenberg, 2007; Hackenberg & Tillema, 2009; Norton, 2008; Steffe & Olive, 2010; Ulrich, 2014). Likewise, the operations and meanings a teacher has available constrain the novel operations and meanings they can potentially construct.

In my experience working with teachers, the relationship between their extant meanings and those QR-based meanings I intend for us to co-construct primarily occurs in two forms. In one form, their extant meanings provide a sufficient foundation for QR-based meanings. For example, reasoning about measurement as a multiplicative comparison between a magnitude and a unit provides a good foundation to understand the unit circle as representing every circle at once (Moore et al., 2016). In a second form, extant meanings provide an insufficient foundation for constructing QR-based meanings. I focus this section on this second form.

A meaning is an insufficient foundation if it does not afford a path of accommodations through which it is modified into an intended meaning.[3] Meanings that are an insufficient foundation for intended meanings can also impede the construction of them. An extant meaning can act as an impediment due to it being habitual to the point a teacher experiences difficulty reasoning in other ways. Or it can act as an impediment due to incompatibilities between it and the intended meaning. Regardless, such cases are complex because it is important to account for and honor their extant meanings while also determining how to support intended meanings (Simon, 1995). This is especially true when intended meanings reflect the mathematics of students. My conviction on this point is empirically driven.

[2] Comparing MKT perspectives is beyond the present scope. I hope that the underlying considerations I provide resonate with readers regardless of MKT commitment. I note that Silverman and Thompson (2008) defined MKT in a way that identifies potential avenues for its development.

[3] It is important that a researcher be deliberate in their characterizing a meaning as an insufficient foundation. I return to this point below to underscore they should only do so through much empirical work in which they skeptically explore the meaning's affordances and constraints.

Across two decades of work with teachers (Carlson, O'Bryan, et al., 2024; Carlson et al., 2013), my colleagues and I frequently experienced instances in which teachers' extant meanings impeded their constructing QR-based meanings (Moore et al., 2026). And when they constructed QR-based meanings, they often privileged their prior meanings both outside and inside their practice.[4] We developed the *competing meanings* perspective as a proof-of-concept response to this phenomenon (Figure 1). Competing meanings is a three-phase cognitive process: first, a teacher's extant meaning is problematized; second, the teacher constructs an alternative meaning to reconcile that perturbation; and third, the teacher reflectively compares the extant and alternative meanings, ultimately critically comparing the utility of the meanings.

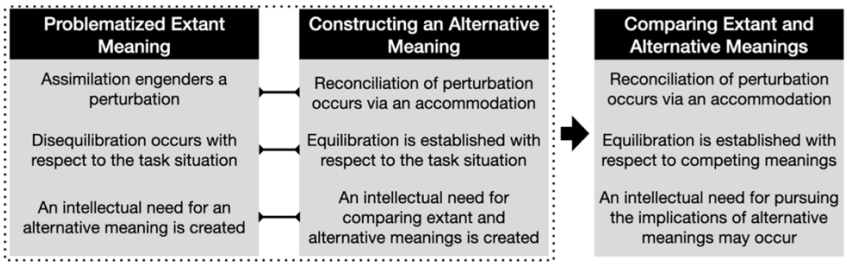

Figure 1: Three Phases of the Competing Meanings Perspective (Moore et al., 2026, p. 6)

When the alternative meaning is an intended meaning reflecting the mathematics of students, the teachers are supported in constructing a meaning pivotal to students' mathematical development. That is, teachers are supported in constructing meanings consistent with Simon's (2006) *key developmental understanding* (*KDU*), which are the meanings we should desire teachers to hold and use. In Moore et al. (2026), we illustrated the competing meanings perspective using a QR-based KDU of function and their graphs. This KDU—based on decades of QR research (e.g., Carlson et al., 2002; Ellis, 2011; Oehrtman et al., 2008; Paoletti & Moore, 2018; Paoletti et al., 2024; Thompson, 1994; Thompson & Carlson, 2017)—foregrounds quantities as simultaneously varying in an invariant relationship. An implication of this KDU is that a function and its inverse are understood as consequences of the same underlying relationship. Because a function and its inverse are derived from the same underlying relationship, representations including graphs and formulas are conceived as capturing it. Each of $y = 3x$, $x = (1/3)y$, and $y - 3x = 0$ symbolizes the same underlying relationship between covarying quantities. Each of the displayed graphs in Figure 2 is an emergent record of the same covariation. Defining the graphs as $y = 3x$ necessarily implies the graphs are defined by $x = (1/3)y$ and $y - 3x = 0$. Although their representational forms can be conceived in terms of multiple quantitative structures (Stevens, 2019, 2026), all representations capture each structure, including that each quantity's change exists in a proportional relationship with the other.

The QR-based KDU can be compared with the common extant meaning of conceiving functions and their graphs as memorized pairings of formula templates, graphical shapes, and function categories or properties (Moore, 2021). To illustrate, teachers frequently reject Figure 2b and Figure 2c as representations of $y = 3x$ because they do not adhere to their memorized pairings. With respect to Figure 2b, they infer the graph cannot be correct because of the location

[4] This was an expected outcome given research on teacher development and teacher change. Their extant meanings have been developed, used, entrenched, and become habitual over years of experience. Additionally, they teach within a system in which they perceive numerous pressures and directives to satisfy.

of x and y (Moore, Silverman, et al., 2019). With respect to Figure 2c, teachers deem it to have a "negative slope" because of its perceptual direction (Moore, Stevens, et al., 2019). In each case, they anticipate a memorized formula-shape-slope pairing and reject a representation that does not belong. Furthermore, their meanings are often incompatible with the QR-based KDU. This produces a tension when teachers construct and explore QR-based meanings. For instance, in Moore, Stevens, et al. (2019) we illustrated a teacher who recognized Figure 2c does contain the points defined by $y = 3x$. She also required that the graph be represented by $y = -3x$ because of its direction. She rejected the graph, but this discrepancy left her confused because she was unable to reconcile it on her own accord; she perceived her meanings to be incompatible with each other. She expressed emphatically that she did not understand the underlying cause of this incompatibility. Her specific words were, "this is so annoying." It is a perturbation like this that we target with the competing meanings perspective. A teacher's realization of an incompatibility they cannot reconcile affords transformative learning opportunities.

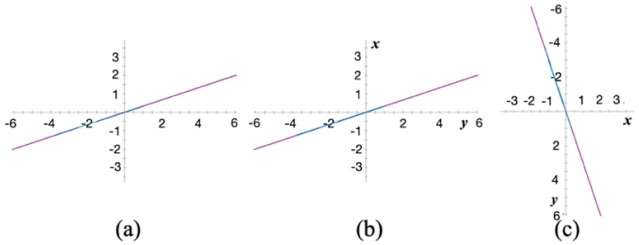

Figure 2: Three Displayed Graphs of the Same Covariational Relationship

The finer details of the competing meanings perspective are in Moore et al. (2026). I raise it to underscore that researchers and educators have an opportunity to create transformative learning experiences by critically considering whether teachers' extant meanings are sufficient for the development of intended meanings. In the context of QR-based meanings, their dominant meanings are typically not, which inhibits their ability to develop meanings researchers have derived from interacting with students.[5] This byproduct of their extant meanings requires that we, as teacher educators, find ways to perturb those meanings and create a need for the construction of QR-based meanings. Furthermore, these perturbations must occur in contexts they view as relevant to their students and practice so that the QR-based meanings have implications for their teaching (Moore et al., 2026; Wasserman et al., 2022).

I close this section by admitting that the incompatibility existing between teachers' extant meanings and QR-based meanings is natural. The incompatibility is not some deficit on the part of a teacher; it's a feature inherent to knowledge development being never-ending. The mathematics of students is not something that traditional curricula reflect, nor is it something that current teachers have likely been exposed to (Simon, 2006; Thompson, 2013). Complicating the matter, the mathematics of students is an always evolving body of mathematical knowledge. As further research occurs, novel models of students' mathematics replace or modify extant models. This is a powerful feature of the mathematics of students, yet its perpetual evolution requires supporting teachers in ongoing learning. We therefore do teachers and their students—both our

[5] I use "dominant" here to imply that, in my experience, teachers technically have the operations available to construct QR-based meanings, but those operations have not been developed, nurtured, and drawn upon repeatedly. They are thus subordinate to extant meanings and their use is somewhat (in their words) foreign and unnatural.

colleagues in co-constructing mathematics—a disservice by not problematizing the compatibility between teachers' extant meanings and the mathematics of students. We should create opportunities for incompatibilities to come to the surface in research and teacher education settings so they can be understood and addressed. The competing meanings perspective offers one proof-of-concept for creating such opportunities. Surely there are additional avenues and perspectives by which researchers and educators can accomplish this goal.

Quantitative Reasoning and Understanding the Mathematics of Students

During a pre-conference podcast, Leatham proposed a principle teacher educators should develop in teachers: "We should care more about our students' mathematics than our own mathematics" (Jones, 2026). His principle is one all educators should share. The question a teacher educator might ask is, "How do we get teachers to care about students' mathematics more than their own?" I contend there is a more productive framing question for his principle.

I anticipate most teachers would answer "Yes" if asked whether they care about their students' mathematics. If asked whether they care more about their students' mathematics than their own, I anticipate a majority would also answer "Yes." Teachers care deeply about their students' mathematics. How they operationalize that care is where we play a role as teacher educators and researchers. A productive framing question is thus, "What cognitive activity is involved in caring about students' mathematics more than one's own?" And, with respect to that question's answer, "How do we support teachers in developing that cognitive activity?"

Caring about students' mathematics. I earlier noted, "the operations and meanings a teacher has available shape how they conceive any situation or topic and they constrain their potential construction of novel operations and meanings." The statement occurred in the context of constructing intended meanings, but it can be modified to be a foundation for caring about students' mathematics. Caring about students' mathematics means attributing to them a mathematics of their own and working to understand and learn from that mathematics (Hackenberg, 2010a). The operations and meanings a teacher has available shape how they understand and learn from their students' thinking.

The act of attributing a perspective of their own to someone else and attempting to understand that perspective is generally termed *decentering*. Piaget first introduced decentering (or *decentration*) to characterize a child's transition from being egocentric to being able to consider alternative perspectives, whether those perspectives be the physical viewpoint of someone or their thoughts, feelings, and experiences (Chapman, 1988; Piaget, 1955; Piaget & Inhelder, 1967). Mathematics educators have since adapted the construct to describe the cognitive activity of constructing and acting upon a model of another's mathematics (i.e., caring about another's mathematics). Decentering is the cognitive mechanism that drives conducting a teaching experiment to build models of students' mathematics (Steffe & Thompson, 2000). Teuscher et al. (2016) identified that understanding teachers' decentering actions is necessary to explain the ways of thinking that promote quality classroom discourse against the backdrop of the mathematics of students. Hackenberg (Hackenberg, 2010a, 2010b; Hackenberg et al., 2024) extensively discussed the relationship between decentering, caring relations, and acts of equity. Ellis (2022) echoed this relationship during a recent annual meeting of this organization and in the context of learning trajectories. Still other researchers (Baş-Ader & Carlson, 2022; Carlson, Bas-Ader, et al., 2024) have detailed decentering's relevance and importance in research, teaching, and teacher education, ultimately developing an associated framework for its use. So, what of potential relationships between QR and decentering? To illustrate, I return to the competing meanings perspective and the Figure 2 graphs. I also consider the Figure 3 graphs.

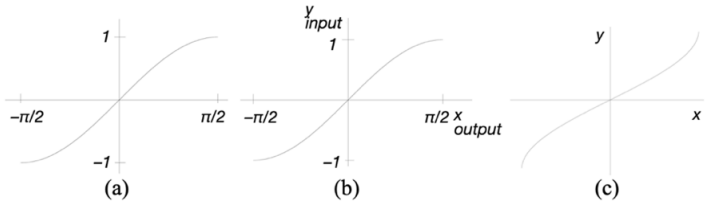

Figure 3: Three Displayed Graphs of the Sine/arcsine Relationship

Our research team has used the graphs in Figure 2 and Figure 3 across multiple studies to explore teacher meanings in relationship to practices we perceive as conventional (Moore, Silverman, et al., 2019; Moore et al., 2026). The graphs target the practices of input or x on the horizontal axis and positive y-values oriented upward. Our typical task progression involves first posing Figure 2a or Figure 3a to teachers as a student created solution to graphing $y = 3x$ or $y = \sin(x)$, respectively. We ask them to determine how a student might have been thinking to produce the solution. We ask them to determine as many ways as possible. We then provide the corresponding Figure 2b or Figure 3b and explain that a student clarified their solution by labeling the axes to indicate their thinking. We prompt the teachers to determine their thinking and comment on its validity. In some cases, we then provide the corresponding Figure 2c or Figure 3c for them to consider in the same manner. We eventually pose, "Well, what if a student claims that this graph (Figure 2c) has a negative slope so it can't be $y = 3x$?" Or, "Another student says they know this graph (Figure 3c) is *also* arcsine. Are both students correct?" Table 1 provides the two predominant response categories during these task sequences.

Table 1: Two Categories of Responses

Category	Response	Figure
I	Ohhhh… this graph is… y is three times bigger than x… x is one, y is three times bigger. Yes. Where x is two, y is three times bigger. So this graph is correct… y is three times bigger than x.	2b
	A clever kid… technically is y equals three x… not the standard way of doing it… They see the relationship between x and y.	2b
	He graphed it completely right. That's y equals three x… He just has a different perspective than… normal classroom settings. But I think it's smart of him to understand that it's not glued.	2b
	They are changing I guess what the input and output is… that is the inverse… with y as your input… this would be you know one equals sine x… you know x has to be pi over two.	3b
II	I feel like you should know your x and y, and like, know which one is which. And, yeah, you're going to get it all wrong I think.	2b
	They messed up the placement of x and y… [*rotating Figure 2b to Figure 2c*]… If you are looking at it this way, it's a negative slope and it should be a positive slope… slope is wrong.	2b-c
	I feel like he's missing the whole concept of a graph… a sine graph's… a graph like everyone knows about, you know.	2b
	This just kind of looks like the sine graph… the graph of an inverse function, like, can't be the same as the original graph.	2b

Category I responses and Category II responses reflect the prior section's KDU and corresponding extant meaning, respectively. Each Category I response involves the teacher conceiving the displayed graph as a consequence of tracking covarying quantities. Each Category II response involves the teacher conceiving the displayed graph in terms of memorized perceptual features and associations with those features. The two categories differ in the extent to which the teachers attribute a viable meaning to the student solution. Category I responses involve a teacher engaging in QR to attribute a meaning that could produce the given graph, while also valuing and considering it correct. Category II responses focus on the incorrectness of the solutions. Category II responses also foreground deficits in student meanings via the teacher imposing their image of a correct solution to identify things not upheld by the student.

Category I responses are consistent with decentering and Category II responses are not. In using tasks like those above, we consistently find teachers who foreground QR-based meanings are better supported in decentering when encountering nonnormative or unconventional student solutions and reasoning (Moore, Silverman, et al., 2019; Moore et al., 2026; Teuscher et al., 2016). Our findings are echoed by several researchers who have illustrated that QR-based meanings are critical to teachers constructing a coherent image of their instruction including interpreting or anticipating student thinking (Carlson et al., 2022; Johnson et al., 2022; Musgrave & Carlson, 2017; O'Bryan, 2025; Rocha, 2023; Tallman & Frank, 2020; Tallman et al., 2024; Thompson, 2016). This finding is sensible because QR-based meanings afford conceiving equivalence among forms of reasoning and representations that initially appear different. More generally, QR-based meanings are sufficient for accommodating to novel situations due to their operations being better suited for processes of abstraction (Moore et al., 2022; Moore et al., 2024). Returning to the examples in Table 1, QR-based meanings enabled the teachers to view the students' unconventional representations as stemming from the same QR driving anticipated conventional solutions. The other teachers merely focused on missing elements of the solutions and explaining that those absences implied the solution is incorrect.

Returning to the classroom, teachers holding QR-based meanings is important because students will create nonnormative, evolving representations in an environment that affords students' QR. diSessa et al.'s (1991) work on students' graphing inventions is an apropos example of this phenomenon. Students' QR is complex, developmental, and not always readily apparent in their solution products (Izsák, 2000, 2003; Kularajan et al., 2024; Moore & Carlson, 2012; Smith III & Thompson, 2007; Thompson & Thompson, 1996). Furthermore, authentic representational acts in a (classroom) community should involve negotiating representational practices for the purpose of establishing convention (diSessa et al., 1991; Moore, Silverman, et al., 2019; Ristroph, 2025; Thompson, 1992, 1995). The implication is that teachers must be prepared to persistently inquire into students' reasoning, identify and foreground their underlying QR, and aid them in ongoing negotiations of representational practices that convey their QR. Such teacher actions are only feasible if teachers develop the QR-based meanings and the decentering actions necessary to understand and act upon their students' thinking. And that turns us to the question, "How do we support teachers in developing that cognitive activity?"

Supporting caring about students' mathematics. The competing meanings perspective provides one answer to this question. We have found success in promoting teachers' inclination to engage in decentering alongside their construction of QR-based meanings using tasks like those discussed above. Their interacting with student products that are nonnormative or violate conventions and yet are created via QR-based meanings acts as a catalyst for the construction of those meanings. And by learning from the students' solutions, they come to value the creativity

and novelty of student reasoning in a way they can operationalize; they come to value putting aside expectations for normative or conventional solutions for the purpose of looking for creative reasoning that underlies students' solutions (see Table 1, Category I). They also express an affective response to identifying creative student thinking, including excitement.

The competing meanings perspective is only a partial response because it is limited in its scope. The cognitive processes associated with the competing meanings perspective only form a foundation for MKT construction. The development of MKT requires that those meanings and decentering orientations be transformed into meanings and orientations with pedagogical power, and a catalyst for this transformation is teachers' decentering activity through sustained work with students (O'Bryan, 2025; Rocha, 2025; Tallman, 2023; Thompson, 2013, 2016). It stands to reason that developmental accounts of MKT that account for teachers' decentering will provide us a direction for shaping experiences that help a teacher "see" their students' mathematics and support QR-based meanings. In fact, recent research provides growing evidence that teachers' decentering is the critical mechanism behind MKT development. In addition to decentering sources provided above, I point the readers to additional detailed sources on this work.

Liang (2021, 2025) drew on theory and empirical work to detail how teachers can learn through their students at a depth that specifies the cognitive mechanisms and processes by which these occur. She also contributed a methodology for investigating teachers' decentering actions. Hodkowski and Smith (Hodkowski, 2018; Smith & Hodkowski, 2025) provided compelling accounts of teachers shifting from a focus on their personal mathematics to the mathematics of students and its impact on their images of instruction. O'Bryan (2025) and Rocha (2023) have each provided a detailed case study of how the development of QR acts as a vehicle for decentering and influences a teacher's ability to create productive learning opportunities for their students that also afford MKT development. Tallman and Frank (2020) and Tallman et al. (2024) identified the importance of teachers being reflectively aware of their meanings and QR, which is supported by decentering actions. Alongside a compelling account of how decentering enables a teacher to support their students' QR, Hackenberg et al. (2025) identified patterns of decentering actions involved in responsive inquiry that give pedagogical power to the mathematics of students. In summary, whether with respect to QR-based meanings or not, the collective work on teachers' decentering actions provides future directions for aiding teachers' development of MKT that productively shapes their care for students' mathematics.

Building on Mathematics of Students to Identify and Explore KDUs

The reader might be surprised by the focus on MKT in this paper. Much of my work foregrounds investigating cognitive meanings of mathematical ideas and providing complementary conceptual analyses, and MKT is hardly mentioned in that work. My goal, however, has always been to support teachers in transforming their practice and, ultimately, their students' learning. Accomplishing that goal requires research on the mathematics of students—who are sometimes teachers—and using that research to redefine the learning goals informing our curriculum, the teaching practices that target those goals, and the research settings within which we conduct our work.

My bias is no doubt shaped by my training with Marilyn Carlson and Patrick Thompson (among others). It is also shaped by empirical experiences with students and teachers inside and outside of research projects. Those experiences continue to reveal that individuals co-constructing mathematical ideas best do so when understanding and building on each other's thinking. In the context of settings like the classroom, it is also critical that they have resources available that support their ability to do so. Unfortunately, this is not the case with most K-16

settings in North America and elsewhere (Carlson et al., 2010; Clements, 2007; McKie et al., 2025; Thompson, 2013; Visnovska & Cortina, 2022). In fact, during my formative work with Marilyn Carlson (Carlson, O'Bryan, et al., 2024), we identified that without curricular materials capturing the mathematics of students, teachers grew exasperated attempting to decenter and effectively support their students' reasoning. The mathematics targeted by their curricular materials did not invite the depth of student engagement and student-teacher interactions necessary for the teachers' intentions or student interest.

Addressing this issue is complex and requires sustained efforts. Thompson (2013) provided some guidance in this regard, and other mathematics educators have painted images of aspirational educational systems and resources (e.g., Baş-Ader & Carlson, 2022; Ellis, 2022; Hackenberg et al., 2025; Liang, 2025; Simon, 1995; Steffe & D'Ambrosio, 1995; Steffe & Wiegel, 1992). The point I underscore to end this paper is that moving toward an educational system that foregrounds the mathematics of students requires that we be more critical of our extant learning goals, topical emphases, and content structuring. The mathematics of students represents a novel and always evolving knowledge body, and thus it should be a permanent starting point and benchmark for identifying and structuring the ideas we target in education (i.e., KDUs). Moreover, we must accept that these ideas can and will run counter to institutionalized and predominant approaches to topics, thus requiring that we break free from these approaches to honor our students' mathematics as a source for our learning and instructional design. As Adiredja and Louie (Adiredja, 2019; Adiredja & Louie, 2020) emphasized, transitioning away from institutionalized narratives and knowledge as superior to students' mathematics is necessary if we wish to focus on student assets, intelligence, and creativity.

As an abridged example, in my work with students and teachers across STEM contexts, I have come to reconceive the relationship between slope and graphing linear relationships. Whereas curricular materials and research predominantly approach slope as a key understanding for linear relationships, I find an alternative framing more productive. The alternative framing is treating slope and rate-of-change as KDUs, and thus each deserving of their own framing and QR-based meanings. It is productive for students to experience the quantification of slope through modeling the inclination of physical objects and the need for quantifying differences in direction. This leads to ideas of measuring slope through percent grade, angle of inclination, and the relative measure of orthogonal change, all subject to unit choice and scale. It is also productive for students to experience the quantification of constant rate-of-change through constructing quantities' covariation and identifying proportional change. This leads to ideas of measuring relative change and representing quantities' covariation in different representations. Neither slope nor rate-of-change is more important than the other, and certainly relationships can be drawn between them. Constant rate-of-change provides a specific measure of slope restricted to coordinate system constraints. Slope applied to a produced graph of a linear function results in the same measure as rate-of-change if using relative orthogonal change under the same scale as the coordinate system. But, as KDUs, rate-of-change quantifies quantities' covariation and slope quantifies an object's physical inclination or direction. I use this suggestive example to call for critically analyzing all mathematical ideas with respect to the reasoning they afford, the goals they accomplish, and the contexts in which they are the foregrounded concept. And, returning to the paper's title, I believe it is imperative that we do this "from-the-ground-up" using the mathematics of students if we want to truly redefine in our students' image the learning-teaching-research playing field we all enjoy.

Generative AI can produce content that appears pedagogically sophisticated, yet mathematics teacher educators face a paradox because the professional reasoning that pre-service teachers must develop is precisely what AI threatens to bypass. We report on an educator preparation provider collaboratory in which teacher educators, the majority in mathematics education, designed, implemented, and reflected on AI-integrated coursework for pre-service teachers. Through cross-case analysis of implementation deliverables and narratives, we identify convergent design principles and organize them in the STEP-AI framework (Developmental Sequencing (S), Structural Transparency (T), and Educational Propagation (EP)). Each of its three dimensions is grounded in use cases from mathematics education courses and corroborated by cases from adjacent preparation courses. Findings inform the practical ways of AI integration in teacher preparation without sacrificing mathematics knowledge for teaching.

Keywords: Teacher Preparation, Generative AI, Mathematical Knowledge for Teaching, Technology Integration

Objectives

When a pre-service mathematics teacher prompts an AI tool to "create a lesson on fraction division for 5th graders," the resulting output may include representations, sequencing decisions, and anticipation of student misconceptions that took the field decades to articulate as expert practice (Ball et al., 2008). This use of AI creates a fundamental tension for educator preparation programs (EPPs). The tool can produce artifacts that *look* like the products of mathematical knowledge for teaching (MKT) without requiring the user to possess or develop that knowledge.

Recent large-scale research on in-service K-12 teachers' authentic AI use established that teachers primarily leverage generative AI (GenAI or AI) as an "implementation bridge," enabling practices they already value but cannot scale within available time (Liu, 2026). Most interactions operated with experienced teachers maintaining professional judgment while offloading production work. This is reassuring for practitioners with established MKT but raises an urgent question for preparation. What happens when the tool user has not yet developed the professional judgment that enables them to distinguish productive use from cognitive offloading?

This question is complicated by a cascading dynamic unique to educator preparation. Teacher educators need to simultaneously develop their own AI integration approaches, model those approaches for pre-service teachers, and prepare pre-service teachers who will carry resulting practices into K-12 classrooms. Prior research thus documents how in-service teachers with established professional knowledge use AI, but little is known about how teacher educators

design AI-integrated coursework for pre-service teachers whose professional judgment is still forming. This gap motivates two research questions:

- How do teacher educators design AI-integrated coursework that balances AI's productive capacity with the development of pre-service teachers' pedagogical reasoning?
- What design principles emerge from implementation experience that inform mathematics teacher preparation's approach to AI integration?

Perspectives

We draw on three bodies of scholarship. First, research on mathematical knowledge for teaching (Ball et al., 2008) establishes that effective mathematics instruction requires specialized knowledge domains, including specialized content knowledge (SCK) and knowledge of content and students, which develop through engagement with mathematical ideas in pedagogical contexts. When a teacher selects fraction representations, anticipates that students will invert-and-multiply without understanding why, or sequences examples to build from measurement to partitive division, they exercise MKT. These decisions resist automation because they depend on knowledge of specific students and classrooms that GenAI cannot access.

Second, practice-based teacher education (Grossman et al., 2009; Lampert et al., 2013) demonstrates that professional judgment develops through structured approximations of practice, such as rehearsals, decompositions, and coached enactments. A pre-service teacher who receives an AI-generated lesson plan has consumed a product; one who iteratively refines prompts while articulating pedagogical rationale has approximated practice.

Third, research on cognitive offloading (Risko & Gilbert, 2016) establishes that decisions to offload depend on perceived task difficulty, confidence in one's processing, and trust in external resources. For pre-service teachers, the risk of inappropriate offloading is elevated because they may trust AI outputs precisely where they lack the knowledge base to evaluate them. Without sufficient guidance and evaluation, the blind trust may occur by default rather than by choice because pre-service teachers have yet to develop the judgment that they would otherwise delegate.

Together, these perspectives converge on an insight: In EPP contexts, the critical question is not merely *how deeply* AI transforms the task or *how much* judgment is offloaded, but *when in the developmental trajectory* AI enters relative to pre-service teachers' own independent engagement with the practice they are still forming. Two design principles follow: (a) Developmental sequencing anchors each AI encounter in prior independent attempts that demonstrate mastery without AI assistance; and (b) structural transparency makes offloading decisions visible to teacher educators and therefore assessable. We use real cases of AI integration in EPP course design to illustrate both principles, tracing the boundary between AI as a shortcut and AI as a thought partner and professional development tool.

Conceptual Framework: STEP-AI

Building on the perspectives, we propose the **STEP-AI** framework to organize design principles into developmental dimensions specific to teacher preparation contexts: Developmental Sequencing (S), Structural Transparency (T), and Educational Propagation (EP) or Cascading Transfer. The framework was developed iteratively: we posited initial dimensions from the perspectives above and refined them against implementation through case analysis described in the Results section, and we present the illustrative version in the Discussion section with the interconnectivity among the dimensions.

Dimension 1: Developmental Sequencing

The first dimension captures *when* in the pre-service teacher's learning trajectory AI is introduced relative to independent engagement in the target professional practice. Unlike in-service contexts where teachers bring established expertise, pre-service contexts require teacher educators to decide about whether AI enters before, during, or after pre-service teachers have engaged in the practice on their own to establish expertise. Sequencing operates as a protective mechanism not because pre-service teachers must attain competence before AI use, but because independent attempts put their own reasoning on record: AI output then complements rather than replaces their thinking, and they have reasoning of their own against which to evaluate what AI produces instead of blindly trusting. As pre-service teachers' evaluative judgment grows across repeated cycles, the boundedness of AI use can progressively relax. The developmental question of whether *the learner (pre-service teacher) has first engaged in the reasoning that AI might bypass* is absent from frameworks designed for practicing professionals.

Dimension 2: Structural Transparency

The second dimension captures the degree to which the AI interaction process itself is made visible, documented, and assessable. Because pre-service teachers are developing professional identity alongside tool use, EPP contexts require explicit visibility into the interaction process, not merely the outputs. This goes beyond disclosure to encompass prompt documentation, revision tracking, comparative evaluation of multiple outputs, and reflective justification of human editorial decisions. To prevent inappropriate offloading, transparency must be *structural* (embedded in assessment design) rather than *aspirational* (offered as a recommendation).

Dimension 3: Educational Propagation (namely Cascading Transfer)

The third dimension captures how AI practices propagate downstream from EPP coursework into K-12 classrooms. Teacher educators design not only for immediate learning outcomes but also for dispositions that will shape how pre-service teachers eventually use AI with their own students. This dimension therefore includes both intentional transfer, such as cultivating evaluative judgment about AI tools that pre-service teachers carry into their teaching, and unintended effects, such as AI habits spreading beyond the boundaries a course was designed to hold. Because the cascade runs from teacher educators to pre-service teachers to K-12 students, from higher education institutions to K-12 classrooms, design decisions propagate across professional generations, and their consequences are harder to observe directly than outcomes within a single course. These three dimensions should operate simultaneously in well-designed AI in EPP integrations.

Methods

Context

The EPP Collaboratory on AI in Teacher Education (January–June 2026) brought together 15 teacher educators from 13 U.S. universities in a six-session design-reflection cycle spanning orientation and goal-setting, use case design, supported implementation, mid-course reflection, and synthesis of shared resources. The collaboratory was initiated by a research center focused on AI in education to produce transferable resources for EPPs nationwide. The facilitator provided free access to an education-specific GenAI platform as computational support, while teacher educators could also choose their preferred AI tools.

Participants

Eleven teacher educators designed and completed full implementations during the six-month period, which constitute the case sample, spanning mathematics education (n=6), educational

technology (n=2), assessment (n=1), linguistics/multilingual education (n=1), and clinical field experience (n=1). Mathematics teacher educators taught across the preparation spectrum: elementary methods, secondary methods, and a dedicated GenAI course (learning technology) serving mathematics pre-service teachers. Institutions ranged from R1 universities to regional comprehensives serving undergraduates, career-changers, and graduate licensure candidates. On a baseline intake survey, teacher educators reported moderate AI confidence (Mean=2.8 on a 5-point scale) and minimal prior use across two separate measures. Regarding prior integration of AI into their coursework, 46% had used AI in only one assignment or activity and 8% reported no prior integration experience. Regarding personal frequency of use, 46% used AI 1–2 times per month and 31% did not use it at all in a typical month.

Data Sources

(a) Implementation deliverables (n=11) were structured post-implementation documents capturing syllabus language, program recommendations, experience-grounded do's and don'ts, and plan-versus-reality reflections. (b) Use case narratives (n=11) were detailed accounts of actual implementations including activity designs, student-facing materials, and observed outcomes.

Analysis

We employed cross-case analysis (Miles et al., 2014), treating each implementation as a bounded case. Because teacher educators designed independently first, convergent patterns across cases represent independent discovery rather than imitation. Within-case analysis identified design logic and observed outcomes; cross-case pattern-matching identified principles that recurred across three or more independent implementations. Insights observed in a single case are reported as illustrative and labeled as such rather than treated as cross-case principles. Consistent with the abductive approach described above, we iteratively refined the STEP-AI dimensions against observed practices through constant comparison (Corbin & Strauss, 2014).

Results

We present findings organized by the three intertwined framework dimensions, grounded in concrete use cases. Regarding the first research question, teacher educators' designs shared a common logic despite disciplinary variety; we identified in each case for where AI was permitted, what independent work preceded it, and how the interaction would be documented and assessed. Mathematics education cases serve as primary evidence, and cases from adjacent preparation courses serve as corroboration interpreted through the lens of MKT. Identifying information has been removed; we reference teacher educators by content area and course type.

Dimension 1: Developmental Sequencing (When AI Enters)

This group of teacher educators' designs converged on requiring pre-service teachers to engage in the target practice independently before AI entered, so that pre-service teachers' initial reasoning was documented and gaps in it became visible to both the pre-service teachers themselves and the teacher educators. The sequencing was cyclical rather than one-shot: independent work and AI-supported work interleaved across repeated cycles, so AI operated *during* development while each encounter remained anchored in and built upon prior independent reasoning process. This pattern was manifested in mathematics education, where the distinction between correct-looking artifacts and underlying pedagogical and mathematical understanding is long-established.

Use Case A: Student work analysis in mathematics methods (Grades 3–9). A mathematics methods instructor designed a four-stage sequence for developing pre-service teachers' capacity to diagnose student mathematical thinking:

Stage 1: Pre-service teachers independently analyze written student work on a fraction task, identifying evidence of understanding, misconceptions, and productive starting points for instruction, with no AI access.

Stage 2: Pre-service teachers engage in an AI simulation where they role-play as the teacher asking diagnostic questions to an AI-simulated K-12 student who exhibits specific mathematical thinking patterns (e.g., treating fractions as whole numbers).

Stage 3: Pre-service teachers receive teacher educator's feedback on their Stage 1 analysis and revise, articulating what they noticed after the AI simulation that they missed initially.

Stage 4: Extended AI simulation with more complex student reasoning (e.g., partially correct conceptual understanding applied inconsistently across problem types).

The critical design insight lies in Stage 1 where, by requiring independent analysis first, gaps in pre-service teachers' diagnostic reasoning became detectable to the pre-service teachers themselves and to the teacher educator. The teacher educator reported that AI integration "revealed gaps in [pre-service teachers]' ability to evaluate the quality of instructional materials and explain why a teaching decision was appropriate." Without sequencing from independent work to AI integration, these gaps would have been masked by the AI-generated products and therefore could not have been purposefully closed. The teacher educator added that "even though students know how to use AI, they should be re-taught how to prompt, evaluate, revise, and reflect," suggesting that general AI familiarity does not guarantee pedagogically purposeful use automatically.

Use Case B: Lesson plan enhancement in secondary mathematics methods. In a secondary mathematics methods course, pre-service teachers used AI to enhance an existing high-quality instructional materials probability lesson plan aligned to 7th-grade Common Core State Standards for Mathematics (National Governors Association Center for Best Practices & Council of Chief State School Officers [NGA Center & CCSSO], 2010). The implicit yet critical sequencing choice was that pre-service teachers began with a *complete, published lesson plan* and used AI to *modify and extend* it, instead of generating one from scratch. This meant pre-service teachers needed to understand the lesson's mathematical goals, anticipate student reasoning about probability, and evaluate whether AI-suggested modifications maintained and enhanced mathematical rigor. Starting from a known-quality artifact, the iterative prompts that were used for modifications required pedagogical reasoning about what to accept, reject, or revise, thus making reasoning processes tractable and assessable.

Use Case C: Bounded integration in linguistics for educators. Though not a mathematics course, this corroborating case illustrates sequencing. In a course on linguistics and language acquisition, AI was introduced only *after* pre-service teachers independently analyzed transcriptions, identified linguistic features in student speech, and formulated initial instructional recommendations. Only then could pre-service teachers use AI to "brainstorm instructional strategies, generate alternative scaffolds, or identify possible blind spots in their analysis [and initial recommendations]."

The teacher educator observed a clear behavioral split. Pre-service teachers who engaged productively with AI described it as a "second opinion," "thinking partner," or "starting point [to revise and build upon]." Those who struggled "initially approached AI as an answer-generator" but shifted with scaffolding. The design principle was explicit: "Define *why* AI is being used, *when* it can be used, when it cannot be used, and *what* human learning you are trying to protect."

Dimension 2: Structural Transparency (Making Reasoning Visible)

Teacher educators who reported pre-service teachers accepting AI outputs uncritically had initially offered transparency as a *recommendation* rather than an assessment *requirement*. Across the cases that addressed critique, structural requirements and intentional design were necessary to produce critical engagement; expecting pre-service teachers to spontaneously evaluate AI outputs was not sufficient. This is not because pre-service teachers deliberately take shortcuts or use AI irresponsibly, but because they are still forming the professional judgment that evaluation requires. Provoking and building that judgment therefore depends on conditions the teacher educators designed to elicit it. The use cases below illustrate this point.

Use Case D: Contrasting multiple outputs in assessment education. An assessment course instructor's experience, which concerned the architecture of critical evaluation, reported as a single-case insight with immediate design utility. When pre-service teachers only reviewed a single AI-generated assessment item or rubric, they "tended to evaluate it as acceptable for classroom use without modification, regardless of its quality." When asked to contrast multiple AI outputs for the same instructional purpose, they "were better able to distinguish certain outputs as better or worse for a given intended use."

Expanding this pattern to the mathematics methods courses, a single AI-generated lesson plan on, for example, fraction division may appear reasonable in isolation. In contrast, comparing three AI-generated plans for the *same* objectives would instead force pre-service teachers to articulate criteria and pedagogical reasoning, such as *which representation sequence better builds conceptual understanding? which plan better anticipates the invert-and-multiply misconception? which provides more productive struggle rather than premature proceduralization?* These are MKT questions that a single AI-generated, seemingly high-quality output can hardly provoke.

The instructor also found that "with little instruction about prompting strategies, the AI tool output that pre-service teachers produced tended to be clearly suboptimal—too general, or too broad." Pre-service teachers lacked the specialized content knowledge to constrain prompts effectively. A prompt like "make an assessment for 4th grade fractions" produces qualitatively different output than "create three items assessing whether students can locate unit fractions on a number line, distinguishing area-model from linear measurement understanding." The latter requires SCK the student has not yet developed.

Use Case E: Process assessment through mini-lesson presentation. In a technology-in-education course, pre-service teachers delivered five-minute mini-lessons to peers. Peers and the teacher educator assessed the live mini-lesson on standards alignment, clarity of objectives, instructional strategies, and student engagement. In addition, the teacher educator designed an extra assessment layer focused on an artifact each pre-service teacher submitted to *document their reasoning process*, which comprised the following elements:

- Original prompts submitted to the AI
- Explicit identification of where the AI's initial output was "flawed or biased"
- Documentation of iterative refinement decisions
- Justification of manual edits made to the final product

This dual structure ensured that "students are developing true critical agency and professional autonomy rather than just learning how to copy and paste from a machine." Some pre-service teachers "simply accepted the first response that AI produced" until required to present their reasoning publicly.

Use Case F: Polished products without understanding. In an educational technology course, the instructor observed a pattern familiar to mathematics educators, namely surface correctness masking conceptual absence: "Some students turned in polished products but struggled to explain why instructional choices were appropriate.... Some students initially viewed AI as a shortcut for completing tasks rather than a tool that still requires professional judgment."

Requiring reflection on the AI process made the gap between production and understanding evaluable; pre-service teachers who could not justify their choices revealed that AI had substituted for reasoning rather than supported it. In this case, the pre-service teachers had drifted into offloading by default; the reflection requirement illustrated by the previous cases could make the offloading decision visible and assessable rather than hidden behind a polished product. The instructor concluded, "Teach [pre-service teachers] how to think *with* AI, not just how to *use* AI."

Dimension 3: Cascading Transfer (Designing for Future Classrooms)

Teacher educators, and mathematics teacher educators in particular, explicitly grappled with how pre-service teachers' current AI experiences would shape their future K-12 practice. In-service teachers shape their students' AI use directly within their current classrooms, where the effects of their decisions are immediately observable and adjustable. In teacher preparation, by contrast, the influence travels a longer path, from teacher educators to pre-service teachers and only later to K-12 students, so design decisions propagate across a professional generation before their consequences appear.

Use Case G: Developing evaluative judgment for professional practice. In a secondary mathematics methods course, pre-service teachers engaged in two parallel AI activities throughout the semester. First, they practiced with AI-simulated students, role-playing as the teacher while the AI exhibited specific mathematical thinking patterns (procedural fluency without conceptual understanding, productive but incomplete reasoning, common misconceptions). Second, they evaluated AI-powered educational technology tools with the NCSM Educational Technology Guidance Rubric for Mathematics Instruction (NCSM, 2025), assessing mathematical accuracy, cognitive demand, and student engagement.

This dual design positioned pre-service teachers as both *users* of AI for their own instructional development and *evaluators* of AI tools for their future students. The instructor noted a dispositional challenge: "Of all the technology tools I taught about in my course, [pre-service teachers] had the most preconceived notions and associated dispositions about AI." One pre-service teacher "was dead set against any use of AI from the beginning and didn't change." This dispositional range, from uncritical adoption to principled refusal, required designs that created space for developing *judgment* rather than mandating a particular stance.

Use Case H: Sustained cultivation of critical dispositions. In a full-semester GenAI course serving pre-service teachers (predominantly in mathematics education), the instructor required hallucination audits, bias audits, iteration evidence, and ethical disclosure for every assignment.

Despite semester-long scaffolding, first-assignment submissions were "full of ethical issues." The instructor observed, "[Pre-service teachers] won't do hallucination audits or iterate with AI. Unless explicitly required, they won't think critically about hallucinations." By mid-semester, with sustained structural requirements, pre-service teachers demonstrated more sophisticated critical engagement. The finding is sobering for single-module approaches. Critical dispositions toward AI required *sustained, repeated* practice across multiple assignments rather than a single workshop or introductory activity.

The teacher educator also raised a cascading concern with K-12 implications: "Don't encourage chatbots for teachers of children below 8th grade. We don't yet know enough about the impact of chatbots on children." Teacher preparation thus carries a distinct responsibility, preparing future practitioners not only to use tools effectively but to judge whether and when those tools should reach their students at K-12 developmental stages.

Use Case I: Unintended habit transfer. An instructor who designed AI-supported simulations for rehearsing instructional decision-making during field placement observed unintended transmitting: "Because I allowed the use of AI for instructional support, [pre-service teachers] also started to rely on it for other assignments that did not allow for AI use."

This unintended transfer created productive classroom conversations about authorship, voice, and human experience, but it also revealed that once established, AI habits can transfer beyond their intended boundaries and harden into overreliance. For EPPs, AI integration policies must therefore consider not only what is explicitly taught but what dispositions are inadvertently cultivated. The dual position of pre-service teachers makes this consideration actionable. Because they are simultaneously students who use AI and future teachers whose students will use AI, their current experience previews what may unfold in their own classrooms. Teacher educators can make this mirror explicit, guiding pre-service teachers to examine their own AI habits, for instance the drift toward overreliance they may themselves exhibit, as evidence of what their future K-12 students will likely experience without deliberate boundaries.

Discussion

These findings address a gap at the intersection of mathematics teacher education and educational technology, namely, how to integrate GenAI without undermining the development of professional reasoning and mathematical knowledge for teaching. The STEP-AI framework organizes design principles that recurred across independently designed implementations.

Developmental Sequencing establishes that each AI encounter should be anchored in and build upon pre-service teachers' prior independent reasoning with the practice. In mathematics methods courses, pre-service teachers first analyzed student work and formulated instructional responses independently before AI complemented that practice. This design made gaps in diagnostic reasoning visible (Use Case A and B) and positioned AI as a second opinion rather than an answer generator (Use Case C). The parallel in mathematics learning is instructive precisely because it is not a fixed order in which one kind of knowledge precedes another. Just as conceptual understanding and procedural fluency develop as intertwined strands rather than in sequence (National Research Council [NRC], 2001), independent reasoning capability and AI-supported work interleaved across iterative improvement cycles in these designs. The principle is not to withhold AI until mastery is attained but to ensure that pre-service teachers always have reasoning of their own against which AI output can be weighed.

Whereas developmental sequencing ensures that pre-service teachers have reasoning of their own to bring to each AI encounter, structural transparency ensures that this reasoning, and how it changes through the encounter, remains visible and assessable for pre-service teachers themselves and the teacher educators. **Structural Transparency** establishes that assessment structures, not instructions, produce critical engagement with AI. The most effective designs made the documented *reasoning process* of prompts, critiques, revisions, and justifications an assessed artifact alongside, or instead of, the final product. The single-case observation that comparing multiple AI outputs provokes deeper evaluation than examining one output has immediate practical utility for methods course design and warrants systematic testing (Use Case D). When transparency was embedded, the public and explicit presentation of reasoning process

ended the acceptance of first responses (Use Case E), and required reflection made the gap between polished products and actual understanding evaluable (Use Case F).

Cascading Transfer establishes that teacher educators design not only for immediate learning but for downstream K-12 classroom practice. This includes intentional design (positioning pre-service teachers as evaluators of AI tools; Use Case G) and attention to unintended effects (AI habits transferring beyond intended contexts; Use Case I). The cascading responsibility, as teacher educators shaping pre-service teachers who will eventually shape K-12 students, requires a longer design horizon than in-service professional development. More importantly, judgments about whether AI tools should reach young learners at all (Use Case H) are ones pre-service teachers must be prepared to make for their future K-12 students, and preparation means learning to ground such judgments in comprehensive information, institutional policy, and criteria oriented toward students' benefit, rather than in personal opinion or belief alone.

Developmental sequencing builds pre-service teachers' own reasoning, and structural transparency makes that reasoning visible; together they supply the grounded confidence pre-service teachers need to model AI integration in their future classrooms through the cascaded transformation, a practice their K-12 students will carry into a workforce where working with AI becomes a baseline expectation (World Economic Forum, 2025). Although teacher educators designed for a variety of courses, they arrived at the same core principle, one that stands at the center of the STEP-AI framework illustrated in Figure 1 below: AI must be bounded, sequenced, and made structurally accountable if it is to produce professional learning rather than professional bypass.

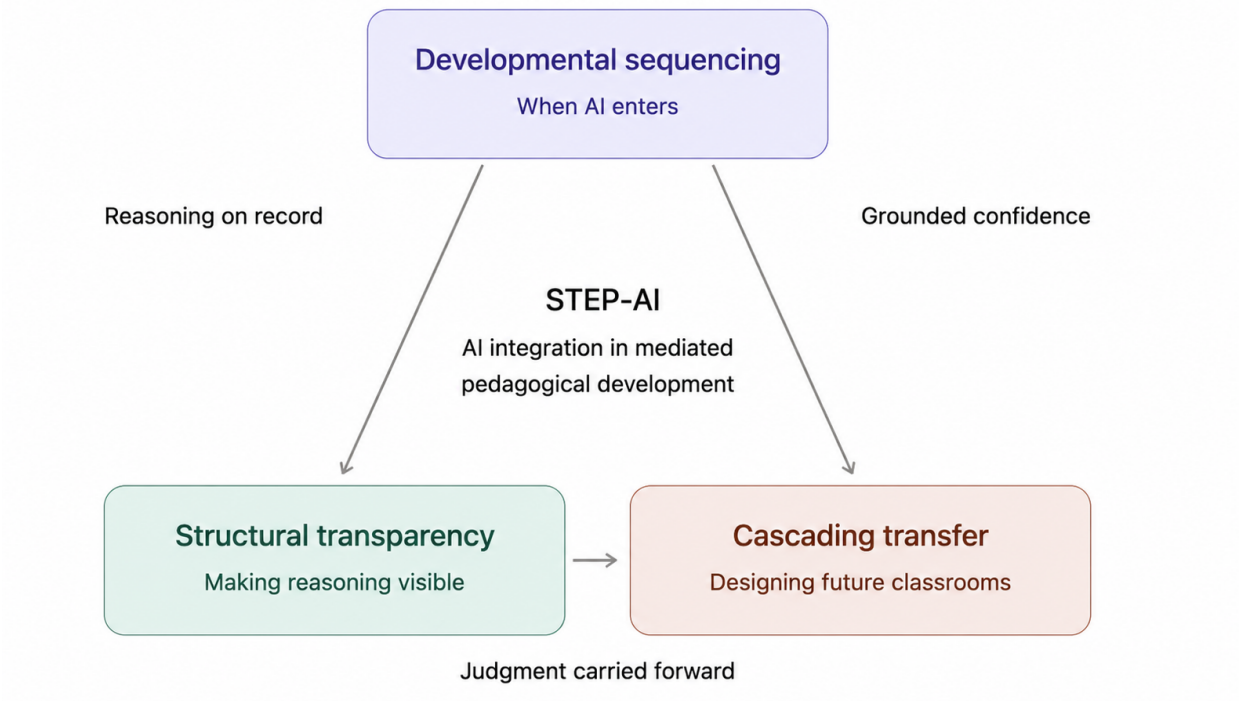

Figure 1: The STEP-AI Framework and Its Three Dimensions for AI Integration in Educator Preparation

Limitations. The collaboratory comprised self-selected teacher educators. Findings reflect their observations rather than direct measurement of pre-service teacher outcomes. Implementations occurred during a six-month period, and the STEP-AI framework was refined against the same cases used to illustrate it, so it requires validation in independent samples. Future work should analyze pre-service teachers' actual AI interactions and track them longitudinally into classroom practice. Because the framework's developmental claim implies that pre-service teachers' professional judgment should grow across iterative cycles of independent and AI-supported work, measuring that professional growth is crucial.

Conclusion. Our results indicate that AI integration in mathematics teacher preparation cannot be treated as an add-on technology module. Across eleven designed implementations, teacher educators converged on the same core logic, organized in the STEP-AI framework: anchor each AI encounter in pre-service teachers' prior independent reasoning (Use Cases A through C), make the interaction process visible and assessable through structural requirements rather than instruction alone (Use Cases D through F), and design for the K-12 classrooms pre-service teachers will eventually lead (Use Cases G through I). AI integration must therefore be embedded within the pedagogical structures through which mathematical knowledge for teaching has always developed in existing study, including approximations of practice, coached rehearsals, and structured reflection. The tool is new; the developmental principles are not.

DESIGNING FOR ARTIFICIAL INTELLIGENCE: RETHINKING CURRICULUM TASKS, TOOLS, AND STUDENT THINKING IN MATHEMATICS

Alden J. Edson
Michigan State University
edsona@msu.edu

Generative artificial intelligence (AI) is rapidly entering mathematics classrooms, yet much of its current use focuses on generating instructional tasks and evaluating answers rather than supporting students' mathematical thinking. I argue that designing for AI requires rethinking curriculum tasks, digital tools, and the mathematical thinking they are intended to elicit. Using proportional reasoning as a case study, I draw on design-based research involving the Connected Mathematics®4 curriculum, the CLUE digital collaborative platform, and a human-developed interpretive framework for students' reasoning. Together, this work illustrates how curriculum and technology can make students' mathematical thinking visible, shareable, and interpretable over time. I conclude by proposing design principles for developing AI that augments teachers' interpretation of student thinking and supports meaningful mathematics learning.

Keywords: Curriculum, Technology, Rational Numbers and Proportional Reasoning, Problem-Based Learning

Introduction

Curriculum has long been recognized as more than written instructional materials. It is realized through the design of mathematical tasks and their enactment in classrooms as teachers, students, and instructional resources interact around mathematical ideas. Remillard and Heck (2014) described curriculum as a dynamic process in which written curriculum is interpreted, enacted, and transformed through instruction, while Choppin et al. (2022) argued that curriculum materials should function as thinking devices that support teachers' and students' mathematical reasoning rather than simply deliver content. Together, these perspectives suggest that curriculum design extends beyond creating instructional materials to designing learning experiences, tools, and supports that shape mathematical thinking over time.

Building on this perspective, my work has examined curriculum as an iterative process in which design, classroom enactment, field testing, teacher feedback, and revision continually shape one another (Edson, 2025; Edson et al., 2025). This work has also informed the design of coherent learning experiences that support students' developing mathematical understanding (Edson et al., 2019) and digital curriculum resources that help teachers access and build on students' mathematical thinking during instruction (Edson & Phillips, 2021). In this paper, I extend this line of work by asking a different question: What aspects of curriculum must be intentionally redesigned if AI is to support meaningful mathematics learning?

The emergence of generative artificial intelligence presents a new challenge for this curriculum enactment process. Much of the current discussion has centered on AI's ability to generate instructional tasks, solve mathematics problems, or evaluate student work. Although these applications may improve efficiency, they do little to deepen our understanding of how students develop mathematical ideas or how teachers interpret that thinking during instruction. If AI is to become a meaningful part of mathematics education, it must be considered as part of the curriculum design process rather than simply another instructional technology.

I argue that designing for AI requires rethinking three interconnected aspects of curriculum: the mathematical tasks students engage in, the digital tools that mediate those experiences, and the ways student thinking is made visible and interpreted. These three dimensions are inseparable. Rich curriculum tasks are needed to develop important mathematical ideas while eliciting meaningful mathematical reasoning. Well-designed tools can preserve, connect, and make visible that reasoning. Human-developed interpretive frameworks provide principled ways of characterizing students' mathematical reasoning and establish the educational foundation for AI systems that support, rather than replace, teacher judgment. In other words, designing for AI begins with designing curriculum that both develops mathematical understanding and reveals students' mathematical thinking. The challenge is no longer simply how to incorporate AI into existing curriculum materials, but how to design curriculum that intentionally creates opportunities for students to develop important mathematical ideas and produce rich mathematical thinking that AI can help teachers interpret and build upon.

Using proportional reasoning as a case study, I draw on a decade of design research involving the Connected Mathematics Project's curriculum, a digital collaborative platform and its tools, and a human-developed framework for interpreting students' reasoning. Collectively, this work illustrates how the focus of curriculum design has expanded, from designing rich mathematical tasks, to designing digital collaborative learning environments, to developing tools and interpretive frameworks that make students' proportional reasoning visible and understandable. I argue that these same principles should guide the design of AI so that it augments teachers' understanding of students' developing mathematical thinking rather than simply automating existing instructional practices.

Rethinking Curriculum Tasks

The mathematical tasks students engage in have long been recognized as the heart of curriculum. They shape not only what students learn, but also how they reason, communicate, and develop mathematical understanding. Tasks can help students develop important mathematical ideas by providing opportunities to grapple with mathematical relationships, justify their thinking, compare strategies, and build conceptual understanding (Stein et al., 1996; Henningsen & Stein, 1997). In problem-based curriculum, a worthwhile task is therefore designed not only to elicit student thinking, but also to advance particular mathematical conceptions and connect them to ideas developed in subsequent tasks. Consequently, the design of worthwhile mathematical tasks has been a central concern of mathematics curriculum research and development for decades.

The emergence of AI does not diminish the importance of curriculum tasks; rather, it heightens it. Current AI systems can generate an endless supply of mathematical exercises, many of which emphasize procedural fluency and the production of correct answers. Yet generating more tasks is not the same as designing better mathematical experiences. If AI is to contribute meaningfully to mathematics education, curriculum developers must first ask what mathematical ideas students should develop and what kinds of mathematical thinking would provide evidence of that development. Only then can AI be designed to recognize, interpret, and respond to that thinking in ways that support instruction.

Over four decades of curriculum development, one lesson has become increasingly clear: worthwhile mathematical tasks do more than develop mathematical understanding—they reveal how students think mathematically. A particular task can help students develop an important mathematical conception, while a carefully sequenced set of tasks can support students in connecting, refining, and eventually consolidating that idea. Successive cycles of classroom field

testing and teacher feedback have continually reinforced this lesson, demonstrating that the quality of curriculum tasks is reflected not only in student learning but also in the mathematical thinking those tasks elicit (Edson et al., 2025). These experiences also reinforced that students' mathematical understanding develops across carefully sequenced investigations rather than through isolated tasks, making the organization of learning opportunities as important as the design of individual problems (Edson et al., 2019). This idea has guided the design of Connected Mathematics®4 (CMP4; Phillips et al., 2025), where individual tasks are intentionally organized into coherent sequences that support the development of important mathematical ideas over time (Edson et al., 2019). Rather than viewing curriculum tasks as isolated exercises, CMP4 organizes learning around coherent sequences of problem-based investigations that invite students to explore meaningful mathematical situations, represent relationships in multiple ways, compare solution strategies, and reflect on what they have learned. The CMP4 STEM Problem Format extends this vision through an "Initial Challenge," followed by "What If…?" questions that encourage students to explore the embedded mathematics within contextual situations, and "Now What Do You Know?" reflections that consolidate important mathematical ideas. Field-test teachers identified the STEM Problem Format as one of CMP4's most effective design features, reporting that it promoted student engagement, extended students' problem solving and mathematical discourse, and created opportunities for students to compare multiple solution strategies (Edson et al., 2025). Collectively, these experiences are designed not simply to produce correct answers, but to develop and connect important mathematical ideas while also making students' mathematical thinking visible through multiple strategies, representations, and explanations.

To better understand how current generative AI supports curriculum design, I compared a proportional reasoning problem from CMP4 with tasks generated by ChatGPT and Microsoft Copilot from a common description of the mathematical goals. All three tasks encouraged students to use multiple strategies, representations, and reflection. The comparison, however, revealed important differences. The AI-generated tasks focused exclusively on proportional situations, whereas the CMP4 problem intentionally juxtaposed proportional and nonproportional relationships to help students develop criteria for determining when proportional reasoning applies. The CMP4 problem also embedded examples of students' mathematical reasoning that students were asked to analyze and critique, while the AI-generated tasks primarily described or referenced possible strategies. Finally, although the AI tasks included broad discussion prompts that encouraged reflection and participation, the CMP4 questions were intentionally designed to advance specific mathematical ideas by directing students' attention to key relationships across strategies, representations, and contexts. Together, these differences illustrate that curriculum design involves more than generating engaging classroom tasks. It requires intentionally designing mathematical experiences that develop conceptual understanding, leverage student thinking as a resource for learning, and guide students toward important mathematical generalizations.

Proportional reasoning provides a particularly compelling illustration (Lamon, 1994; Ben-Chaim et al., 1998). Rich proportional reasoning tasks rarely produce a single pathway to a solution. Students may reason additively or multiplicatively, build up through repeated relationships, use unit rates, scale quantities, construct tables, graphs, equations, or diagrams, and justify their reasoning in different ways. From a curriculum perspective, these variations are not incidental; they are a strength rather than a complication. They are precisely the evidence teachers need to understand students' developing mathematical thinking. Different approaches

reveal different understandings of multiplicative relationships, creating opportunities for teachers to build on students' existing reasoning while also defining the kinds of evidence AI must eventually learn to interpret. They also provide the kinds of rich mathematical activity that AI must eventually learn to interpret if it is to support classroom instruction in meaningful ways.

Designing rich curriculum tasks, however, is only the beginning. Once students begin generating diverse strategies, representations, and explanations, a new challenge emerges: how can this thinking be preserved, shared, and interpreted as it develops? The lesson for curriculum design is that worthwhile tasks should be judged not only by the mathematics they teach, but also by the mathematical thinking they elicit. That thinking becomes the foundation upon which teachers, and eventually AI, can interpret, respond to, and extend students' learning. Addressing this challenge requires rethinking the tools that support, preserve, and make visible students' mathematical thinking.

Rethinking Classroom Tools

Rich mathematical tasks alone are not enough. Although carefully designed tasks can elicit rich mathematical thinking, much of that thinking disappears unless it can be preserved, shared, and interpreted. As students engage in meaningful problems, they produce a wide range of strategies, representations, explanations, and questions. Yet much of this thinking is fleeting. Ideas shared during small-group discussions may never reach the whole class. Intermediate representations are often erased or discarded. Teachers frequently make instructional decisions based on only a fraction of what students know and understand. If curriculum is to support students' developing mathematical thinking, the tools that mediate classroom activity must be intentionally designed to preserve, connect, and make visible that thinking.

Conventional classroom tools have served mathematics education well. Paper and pencil, whiteboards, graph paper, manipulatives, and calculators each provide important ways for students to explore mathematical ideas. However, these tools were not designed to capture the evolution of students' thinking over time or to support teachers in interpreting patterns of reasoning across individuals, groups, and classroom discussions. The lesson for curriculum design is not that traditional tools are inadequate, but that new forms of mathematical activity require new kinds of tools.

Building on the problem-based design of CMP4, we sought to design digital collaborative tools that extend, rather than replace, students' mathematical activity while also supporting teachers' enactment of problem-based mathematics curriculum (Edson & Phillips, 2021). Figure 1 illustrates this shift. Students engage with the CMP4 curriculum in a shared digital workspace where they solve problems using text, tables, graphs, drawings, equations, and images while documenting, revising, and communicating their mathematical thinking. Unlike traditional classroom tools, their work persists over time, allowing ideas to be revisited, refined, connected across problems and investigations, and shared with peers. Rather than producing isolated solutions, students create a growing collection of mathematical artifacts that support collaboration and make their thinking visible throughout the learning process.

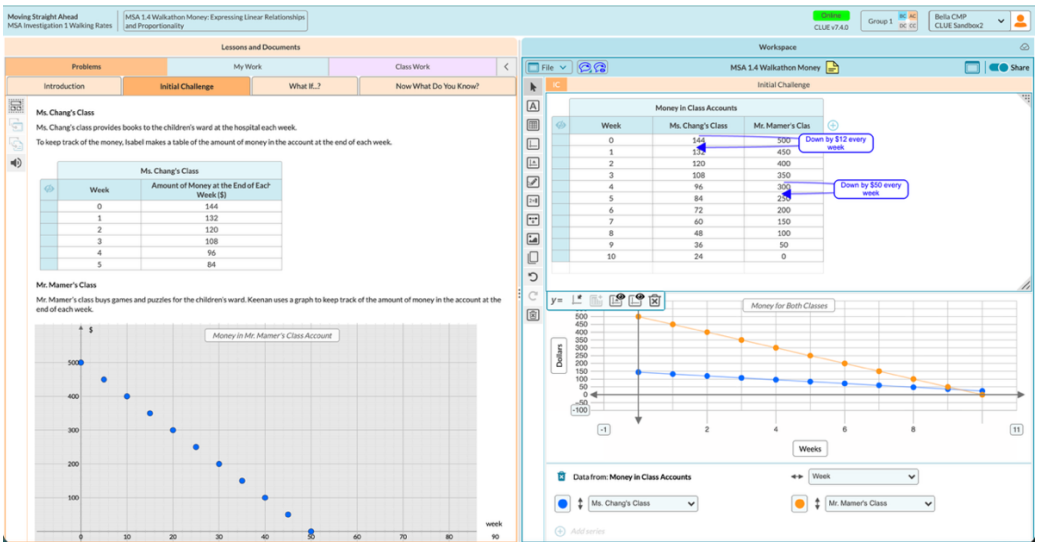

Figure 1: A Digital Collaborative Environment that Enables Students to Represent, Revise, and Share Mathematical Thinking Using Multiple Representations

Figure 2 illustrates the complementary role of the teacher. Teachers can access curriculum materials alongside students' developing work, monitor individuals, groups, or the entire class in real time, identify emerging strategies, compare approaches, select student work for discussion, and incorporate that work into subsequent instruction. In this way, the digital tools become part of the operational curriculum, supporting teachers' ongoing interpretation of students' mathematical thinking rather than simply delivering digital content (Edson & Phillips, 2021; Edson, 2024).

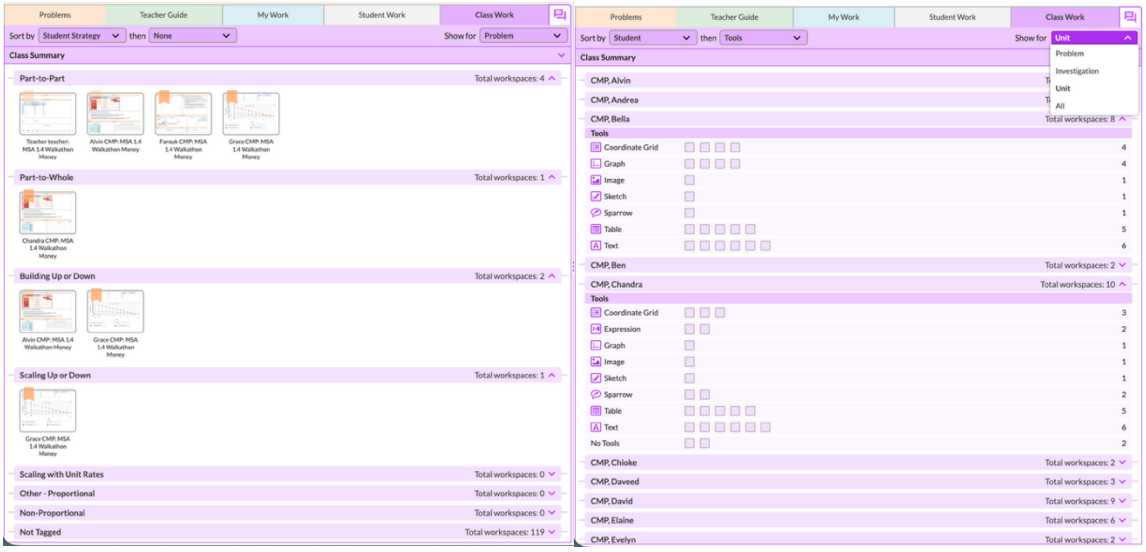

Figure 2: Teacher Dashboard that Supports the Interpretation of Students' Mathematical Thinking During Classroom Instruction

Subsequent classroom studies demonstrated that these environments not only preserved students' mathematical work but also transformed that work into an instructional resource for

both students and teachers (Park et al., 2024). Students could revisit, refine, and build upon their own and their peers' mathematical ideas across problems and investigations, while teachers used these persistent records to identify emerging strategies, orchestrate classroom discussions, and inform subsequent instructional planning. Rather than disappearing when group work ended, students' inscriptions became shared classroom resources that teachers could revisit during instruction, planning, and reflection (Park et al., 2024). Teachers, in turn, can monitor students' work in real time, identify emerging strategies, select work for whole-class discussion, and build on students' mathematical ideas as instruction unfolds through dashboard tools specifically designed to support teacher decision making during instruction (Edson & Phillips, 2021). Research also suggests that access to persistent evidence of student thinking influences teachers' collaborative planning, prompting them to reconsider when and how digital and non-digital resources best support students' mathematical understanding (Park & Edson, 2024). Rather than simply delivering content, these tools become part of the operational curriculum, supporting the interactions among curriculum materials, teachers, and students envisioned by Remillard and Heck (2014), while making students' mathematical thinking persistently visible throughout the learning process (Edson, 2024). Recent work has begun extending these digital collaborative environments with curriculum-aligned AI that uses interpretive rubrics to organize and summarize students' mathematical thinking rather than simply generate answers or evaluate correctness (Bondaryk et al., 2026).

Designing these tools also revealed an important lesson. Making students' work visible did not necessarily make their mathematical reasoning interpretable. During our analyses of students' proportional reasoning, we found that critical mathematical relationships often remained implicit, even when multiple representations were available. This realization led to the development of Student Proportional Reasoning Arrows (SPArrows), a representational tool that enables students to explicitly communicate proportional relationships within and across representations (Edson et al., 2024). Rather than functioning as an AI technology, SPArrows was designed to strengthen students' mathematical communication while making their reasoning more visible to teachers, researchers, and future AI systems (Edson et al., 2024). The broader lesson was that visibility alone is insufficient; curriculum tools must also help make students' mathematical reasoning interpretable.

These experiences suggest that the role of classroom tools must also be reconsidered in the age of AI. Their purpose extends beyond delivering content or collecting answers. Well-designed tools mediate mathematical activity, support collaboration, preserve students' evolving thinking, and provide richer evidence for instructional decision making. Empirical studies suggest that when students' mathematical thinking becomes persistently visible and accessible, teachers are better able to notice emerging strategies, orchestrate discussions around student-generated ideas, and use evidence of student thinking in subsequent instructional decisions (Park et al., 2024). The lesson for curriculum design is that tools should be judged not only by the activities they support, but also by how well they make students' mathematical thinking visible and interpretable. Only when rich curriculum tasks are coupled with tools that make students' mathematical thinking visible and increasingly interpretable can AI begin to support teachers' understanding of students' developing reasoning.

Rethinking Student Thinking

Making students' mathematical thinking visible is an important step, but visibility alone is not enough. Teachers must still interpret what they see. A student's table, graph, diagram, equation, or written explanation does not automatically reveal the mathematical ideas that

underlie the work. Instead, teachers draw on their mathematical knowledge and professional judgment to recognize emerging understandings, misconceptions, and opportunities for extending learning (Jacobs et al., 2010; Sherin et al., 2011). If AI is to support this process, it must be designed around principled interpretations of student thinking rather than simply identifying correct or incorrect answers.

Proportional reasoning illustrates the interpretive challenge particularly well. The same student work can provide evidence of multiple dimensions of mathematical thinking, and those dimensions may not be immediately apparent from an answer alone. For example, a correct solution may reflect different understandings of the relationships among quantities, just as an incorrect solution may reveal productive reasoning that can be extended. Interpreting such work therefore requires attention not only to what students produce, but also to the mathematical relationships their representations and strategies reveal. This complexity makes proportional reasoning a useful context for developing principled ways to characterize student thinking, ways that can support teachers' interpretation of student work, and ultimately, provide a foundation for AI systems designed to assist rather than replace that interpretation.

This interpretive challenge led us to develop a human-centered framework for interpreting students' proportional reasoning. Rather than beginning with AI models or automated classification systems, we began with mathematics. Through iterative analyses of authentic student work, we identified three complementary dimensions of students' reasoning: the mathematical representations students used to communicate their thinking, the approaches they took to proportional situations, and the strategies they employed to solve problems. To operationalize this framework, we developed a rubric (without AI) that distinguishes these dimensions of students' reasoning and provides a principled basis for analyzing authentic student work before any AI analysis is undertaken (Edson et al., in press). Table 1 provides an at-a-glance summary of the rubric. Rather than reducing student work to correct or incorrect answers, the rubric captures meaningful differences in students' mathematical reasoning while remaining grounded in mathematics education research and classroom practice.

Table 1: Human-Developed Rubric for Students' Proportional Reasoning

Criterion and Associated Elements		
A. Student Representation – Student proportional reasoning representations based on their inscriptional resource used in the digital collaborative CLUE platform:		
1. Coordinate Grid	**4.** Image (uploaded photo)	**7.** SPArrow
2. Expression (or equation)	**5.** Number Line	**8.** Table
3. Graph	**6.** Sketch (drawing)	**9.** Text
B. Student Approach – Student proportional reasoning approaches to the contextual problem using reasoning about:		
1. Part-to-Part	**2.** Part-to-Whole (or Whole-to-Part)	
C. Student Strategy – Student proportional reasoning strategies include:		
1. Building Additively	**3.** Using a Multiplicative Relationship	
2. Scaling Up or Down Multiplicatively	**4.** Other Proportional Reasoning	

The rubric serves a second purpose beyond supporting teachers' interpretation of student thinking. It is also being used to construct a large human-coded dataset of students' proportional

reasoning drawn from authentic classroom work across the seventh-grade CMP4 curriculum. Researchers code each instance of student work according to its mathematical representation, proportional reasoning approach, and solution strategy, producing structured data that preserve meaningful distinctions in students' reasoning. Rather than training future AI systems directly from raw student responses or correctness, this work establishes an educationally grounded dataset through which AI can learn from mathematics educators' interpretations of student thinking (Edson et al., in press).

This progression, from curriculum tasks to student work, to human interpretation, to a human-coded dataset, is intentional. Before AI can interpret students' thinking, educators must first establish what counts as meaningful mathematical thinking. Human-developed interpretive frameworks provide this foundation. They reflect decades of research on proportional reasoning, classroom teaching, and curriculum design while making explicit the features of student work that matter instructionally. The resulting human-coded dataset preserves these educational judgments so that future AI systems learn from principled interpretations of students' mathematical thinking rather than from correctness alone. This design philosophy is now being operationalized within CLUE through AI that uses curriculum-specific interpretive rubrics to identify students' approaches, representations, and strategies while supporting teacher noticing and student reflection (Bondaryk et al., 2026).

This perspective reframes the role of AI in mathematics education. Rather than generating tasks or evaluating answers, AI has the potential to assist teachers by recognizing patterns in students' strategies, representations, and approaches as they develop over time. Such systems would not replace teachers' professional judgment; instead, they would extend teachers' capacity to notice, interpret, and respond to students' mathematical thinking across individuals, groups, and classrooms. The lesson for curriculum design is that designing for AI requires designing principled ways to understand student thinking before designing AI systems to interpret it.

Design Principles for AI-Enhanced Curriculum

The preceding discussion suggests that the emergence of generative artificial intelligence requires more than new technologies; it requires a reconsideration of how mathematics curriculum is designed. AI should not be viewed as an instructional add-on or as a replacement for teachers' professional judgment. Rather, it should be understood as one component of a broader curriculum system in which mathematical tasks, classroom tools, and human interpretations of student thinking work together to support learning. Drawing on the lessons from this work, I propose four design principles for AI-enhanced mathematics curriculum.

Design Principle 1

Curriculum tasks should be judged not simply by whether they produce correct answers, but how well they support the development of important mathematical ideas and elicit evidence of students' developing thinking. As the comparison between the CMP4 investigation and AI-generated tasks illustrated, generating mathematically appropriate problems is not the same as designing curriculum. Curriculum tasks should intentionally develop and connect important mathematical ideas through carefully sequenced questions, meaningful contexts, opportunities to compare strategies, and structured reflection. Individual tasks can introduce or advance particular mathematical ideas, while sequences of tasks can support students in connecting, refining, and consolidating those ideas over time. When designed in this way, tasks both support meaningful mathematical learning and produce the rich evidence of student thinking that both teachers and future AI systems require to support learning.

Design Principle 2

Rich mathematical tasks alone are insufficient if students' thinking disappears once the lesson ends. Curriculum tools should therefore be designed to preserve, connect, and communicate students' mathematical reasoning across individuals, groups, and classroom discussions. Digital collaborative environments, representational tools, and teacher dashboards should not simply digitize existing instruction; they should transform students' work into persistent instructional resources that teachers can revisit, interpret, and build upon during and after instruction. AI becomes valuable only when it has access to rich, persistent records of students' developing mathematical thinking.

Design Principle 3

Before AI can recognize meaningful mathematical thinking, mathematics educators must first determine what meaningful understanding and evidence of that understanding matter instructionally. Human-developed interpretive frameworks and rubrics make explicit the mathematical distinctions that matter instructionally. These frameworks also provide the foundation for constructing educationally grounded datasets that preserve expert interpretations of student reasoning. Rather than learning directly from correctness or large collections of student responses, future AI systems should learn from these principled interpretations of students' approaches, representations, and strategies. In this way, AI becomes grounded in mathematics education research rather than statistical patterns alone.

Design Principle 4

Designing for AI is fundamentally a curriculum challenge rather than a technological one. AI should augment, not replace, the expertise of teachers and curriculum developers. Rather than generating lessons or evaluating answers in isolation, AI should help teachers interpret evidence of students' developing mathematical understanding, notice patterns in students' mathematical thinking, organize evidence across time, identify emerging understandings, and support instructional decision making. This vision requires sustained collaboration among curriculum developers, mathematics educators, teachers, learning scientists, and AI researchers so that advances in AI remain grounded in how students actually learn mathematics.

Taken together, these principles represent an evolution in curriculum design. The focus shifts from designing instructional materials alone to designing integrated curriculum systems in which tasks elicit meaningful thinking, tools preserve that thinking, interpretive frameworks make it understandable, and AI extends teachers' capacity to build on students' developing ideas. The future of AI in mathematics education therefore depends less on increasingly sophisticated algorithms than on increasingly sophisticated curriculum design. By intentionally designing these elements together, curriculum developers can create learning environments in which AI meaningfully supports students' mathematical learning while strengthening, rather than replacing, teachers' professional judgment.

Conclusion

Generative artificial intelligence is often presented as a technological innovation that will transform mathematics education. I have argued for a different perspective. The more significant challenge is not designing increasingly sophisticated AI systems, but designing curriculum that elicits, preserves, and supports the interpretation of rich mathematical thinking.

Using proportional reasoning as a case study, I have illustrated how decades of curriculum design research have progressively expanded what can be learned about students' mathematical thinking. Carefully designed tasks develop important mathematical ideas while eliciting diverse reasoning. Thoughtfully designed classroom tools preserve and extend that reasoning. Human-

developed interpretive frameworks provide principled ways of understanding students' approaches, representations, and strategies. Together, these developments establish the educational foundation upon which meaningful AI systems can be built.

This progression also represents an evolution in curriculum design. The focus is no longer solely on designing instructional materials, but on designing integrated curriculum systems in which tasks elicit rich mathematical thinking, tools preserve that thinking, interpretive frameworks make it understandable, and AI extends teachers' capacity to interpret and respond to students' developing ideas.

The future of AI in mathematics education will depend less on advances in algorithms than on advances in curriculum design. As curriculum developers, mathematics educators, teachers, and AI researchers work together, the goal should not be to automate instruction, but to strengthen teachers' capacity to notice, interpret, and respond to students' developing mathematical thinking. Doing so requires intentionally designing mathematical tasks, classroom tools, interpretive frameworks, and AI systems as complementary components of a coherent curriculum. When these elements are designed together, AI becomes not the driver of curriculum, but a curriculum partner that helps teachers understand, interpret, and build on students' mathematical thinking while preserving the central role of human judgment in mathematics teaching and learning.

Orly Buchbinder
University of New Hampshire
orly.buchbinder@unh.edu

This paper introduces the conceptual framework "AI Integration in K-12 Mathematics: A Framework Linking Curriculum, Classroom Enactment, and Student Learning (AIM-CEL)." It outlines the relationships among the official, teacher-intended, and enacted mathematics curriculum specific to AI integration, along with related student outcomes and affecting factors. The framework was used to analyze survey data from in-service secondary mathematics teachers enrolled in a graduate program about their perspectives on AI integration in mathematics. The results reveal that teachers' perspectives toward AI integration vary from reluctance and resistance to support for strategic, intentional use of AI. Both groups demonstrated agency, framing their positions in terms of supporting students' learning outcomes. The discussion covers the relationships among factors that influence teachers' decisions about AI integration.

Keywords: teacher agency, artificial intelligence (AI), mathematics curriculum

Artificial intelligence (AI) and its subset, generative artificial intelligence (GenAI), are catalyzing transformative changes to the mathematics curriculum by providing new possibilities and opportunities to meet student needs (Arslan et al., 2024; Batta, 2024; Opesemowo et al., 2024). AI systems can perform cognitively demanding tasks, engage in complex reasoning that mirrors intelligent behavior, while GenAI uses complex models to create new content, facilitate more natural human-like interactions, and support a variety of tasks (Peñalvo & Ingelmo, 2023; Van Vaerenbergh & Pérez-Suay, 2022). In the United States (U.S.), national mathematics organizations and federal policies promote the use of AI in K-12 education, with the assumption that AI can support instruction and efforts to promote student learning without diminishing opportunities for students to engage in problem solving or exhibit critical thinking skills (Department of Labor, 2026; White House, 2026; NCTM, 2024).

As AI becomes more prevalent in educational settings and policy mandates continue to encourage its integration into mathematics curricula, the role of teachers becomes particularly critical since they are tasked with implementing these curricula and assessment policies (Long & Lampen, 2014). When teachers take stances and make decisions that can affect their professional lives within their sociocultural contexts, they exercise their agency (Sang, 2022). Teachers' decision-making and actions affect how mathematical tasks are set up and differentiated, how the physical and cognitive classroom spaces are organized, and how student engagement with mathematical content is coordinated, all of which ultimately impact students' learning (Long & Lampen, 2014; Smith & Stein, 2023). However, little is known about how advancements in AI educational technology interact with and affect teacher agency. Therefore, there is a need to examine the agency of secondary mathematics teachers regarding AI integration to understand the uptake or lack thereof of AI and GenAI in mathematics classrooms, and to tailor professional support for teachers to facilitate that uptake in meaningful and ethical ways (Alsina & Vasquez, 2024; Biesta et al., 2015). To understand the interplay of teacher agency in integrating AI into the mathematics curriculum, we developed a conceptual framework (described below) and used it in a study with in-service secondary teachers. The following research questions guided our inquiry: *How do secondary mathematics in-service teachers (who are graduate students)*

perceive AI integration into the official, teacher-intended, and enacted mathematics curriculum, and how do they see AI integration impacting student learning outcomes? What factors do they perceive as contributing to the integration of AI? To what extent do teachers perceive having agency in an AI-integrated mathematics curriculum?

Theoretical and Empirical Backgrounds

Teacher Agency in the Era of AI

Sang (2022) defined teacher agency as "the capacity of teachers to act purposefully and constructively to direct their professional growth and contribute to the growth of education quality" (p. 2). Teachers may exhibit resistance to change or hesitation to conform to top-down policies due to distrust in the extent to which the policies align with their classroom realities and skepticism about how these changes affect their efforts to support students' learning of mathematics (Jita et al., 2025; Wright, 2021). To advance sustainable educational change, teachers should be empowered to facilitate and lead it, reflecting a bottom-up approach and aligning with top-down policy shifts (Wright, 2021).

With respect to AI integration, teachers' agency may be influenced by their AI literacy, ethical considerations, and knowledge about the suitability of AI tools (Jita et al, 2025). Teachers' epistemic agency is a subset of teacher agency and encompasses teachers' ability to construct and evaluate knowledge, enabling them to critique AI and its output rather than passively accept AI-generated content (Chu & Wang, 2025; Jose et al., 2025; Nieminen & Ketonen, 2024Urbani, 2024;). When exhibiting epistemic agency, teachers engage in "trust audits," questioning and critically examining AI outputs (Jose et al., 2025). Thus, as teachers exercise teacher agency, there may be evidence that they also demonstrate epistemic agency.

Mathematics Teachers Perspectives towards AI

Studies have shown that teachers perceive that AI can promote personalized learning, enhance classroom instruction and discourse, provide immediate feedback on assessment, improve students' problem-solving skills, increase efficiency by automating repetitive tasks, and promote collaboration (Albalawi, 2025; Ballenas & Lasco, 2025; Clarke, 2025; Korkmaz et al., 2025; Meylani, 2024; Sears, Castro-Minnehan et al., 2026; Walkington, 2025). On the other hand, teachers also acknowledge the need to address ethical considerations of AI use and to be cautious of students becoming over-reliant on AI tools, thus reducing the cognitive rigor of their mathematical engagement (Busuttil & Calleja, 2025; Chounta et al., 2022; Clarke, 2025; Egara & Mosimege, 2024; Meylani, 2024; Sears et al., 2025). Additionally, teachers expressed concerns about their own limited personal experience and lack of professional training on AI have been identified as barriers to AI integration in mathematics classrooms (Korkmaz et al., 2025; Meylani, 2024).

While prior research catalogs teachers' perceptions about AI-related benefits or challenges, in their current form, these findings offer a limited view of teacher reasoning. To make these insights usable for researchers and mathematics educators, it is necessary to understand how these perceptions can be classified and characterized. Toward this aim, we propose a conceptual framework to map teachers' AI-related perceptions across the domains of official, teacher-intended, and enacted curricula, as well as student learning outcomes. Because curricular systems structure and constrain what teachers do, or perceive they cannot do, in practice, situating perceptions within these domains provides a more coherent and actionable account of how teachers make sense of AI in their work.

Conceptual Framework

To capture various aspects of AI integration in school mathematics, we (the authors) propose

a conceptual framework, which we term *AI Integration in K-12 Mathematics: A Framework Linking Curriculum, Classroom Enactment, and Student Learning,* or the *AIM-CEL Framework* for short. Drawing on two existing frameworks: the *Curriculum Policy, Design and Enactment System* (Remillard & Heck, 2014) and the *Instructional Technology Tetrahedron* (ITT) model (Buchbinder, Liu, & Towle, 2025; Liu & Buchbinder, 2024), we envision how AI is integrated in and affects various aspects of curriculum, classroom enactment, and student learning. By curriculum, we mean both the planned and the actual learning experiences designed to help learners reach particular objectives (Remillard & Heck, 2014). Additionally, the *AIM-CEL* Framework considers various factors affecting AI integration within official, teacher-intended, and enacted curriculum as well as students' learning outcomes (see Figure 1).

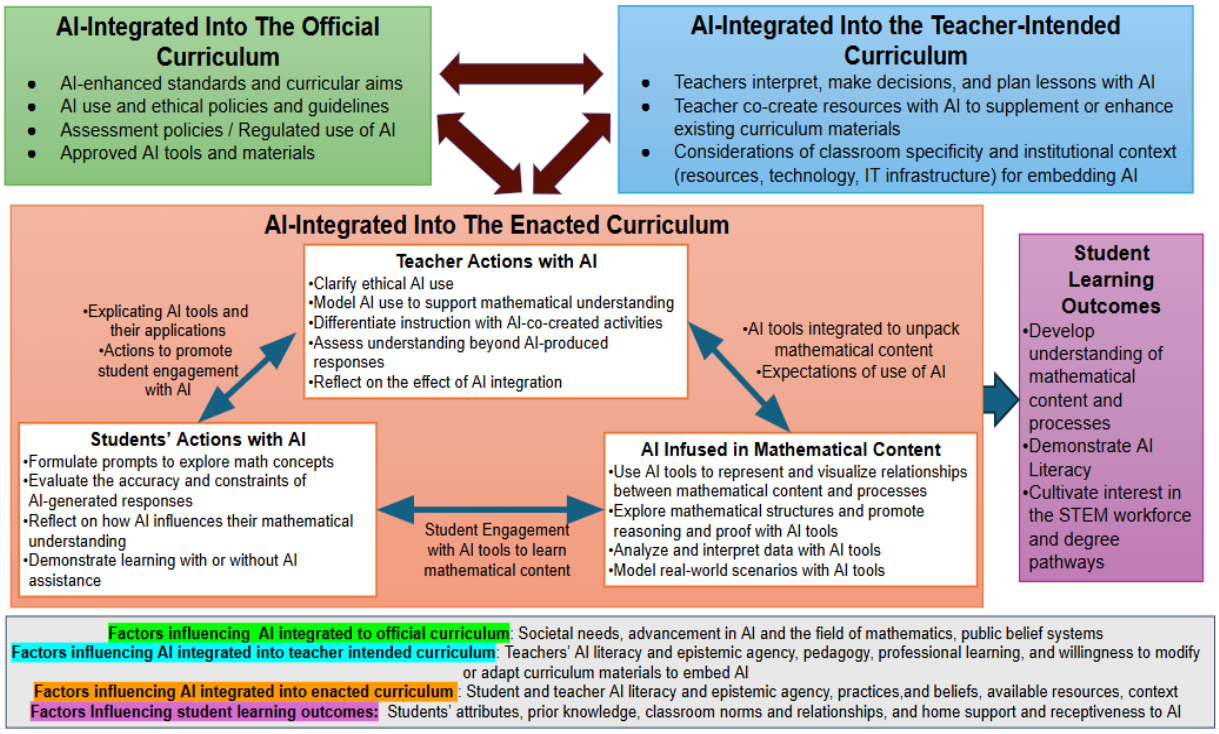

Figure 1: AI Integration in K-12 Mathematics: A Framework Linking Curriculum, Classroom Enactment, and Student Learning

The first component of the *AIM-CEL* Framework involves the *official* curriculum, which, in the US, involves curricular aims and objectives, standards, and assessment structures authorized at the national, state, or district levels. The official curriculum provides overarching policies and guidelines for integrating AI into mathematical standards, curriculum materials, assessment structures, and approved tools. The second *AIM-CEL* Framework component concerns a teacher-intended curriculum, examining how individual teachers interpret official AI policies and integrate them into their planned curricula. In this process, teachers make decisions about which AI tools to use, if at all, for what purposes, and in what ways by considering the specificity of their classroom and institutional context. Based on these considerations, teachers devise lesson plans and instructional resources, often with the aid of AI (e.g., co-creation), to enhance or replace existing curricular materials.

The *enacted* curriculum corresponds to the interactions among students, teachers, and

instructional materials as they unfold in mathematics classrooms. To conceptualize AI integration within this component of the *AIM-CEL* Framework, we draw on the Instructional Technology Tetrahedron (ITT) model (Buchbinder et al., 2025; Liu & Buchbinder, 2024). The ITT model emphasizes the role of technology as both a tool and a medium for classroom interactions. In the *AIM-CEL* Framework, AI technology is diffused throughout the teacher, students, and content vertices, and the arrows represent connections among them. Teacher actions with AI involve promoting ethical use of AI to support students' mathematical understanding, differentiating instruction, and modeling efficient AI use. The student actions involve directly interacting with AI by formulating prompts, evaluating AI responses in terms of mathematical accuracy, and possible constraints or biases. The framework also considers how students' learning with or without AI is demonstrated during the lesson. The content vertex of the framework represents AI-infused instructional materials. It considers the use of AI to represent mathematical concepts, processes, relationships, data, and real-world phenomena, as well as how AI is used to explore and reason about these mathematical objects and relationships.

The AIM-CEL Framework further outlines the bi-directional relationships among the vertices within the enacted space. The teacher facilitates the integration of AI content and sets expectations for its use. The teacher also explicates AI tools and promotes their use by students, who, in turn, engage with AI-infused content in their learning environment. Since "digital technology is saturated with humanity through its design and conception to the extent that it can be seen as having its own agency" (Liu & Buchbinder, 2024, p. 437), we conceptualize AI-infused mathematical content as "interacting" with both teachers and students. The official, teacher-intended, and enacted curricula mutually affect each other, as captured by the brown double-sided arrows (Figure 1). The ultimate goal of the curriculum network is to support students' learning outcomes, which may include developing mathematical understanding, skills, practices, communicative skills, strategic competence, and productive dispositions (NASEM, 2018; NRC, 2001). In the era of AI, student learning outcomes should also include developing AI literacy and cultivating curiosity about and interest in STEM disciplines.

In the following section, we describe a study that used the *AIM-CEL* Framework to analyze data from secondary mathematics teachers. We highlight the affordances of the framework for illuminating complex relationships in teachers' perspectives on AI integration across the curriculum, as well as the factors affecting this process.

Methods

Study Setting and Participants

The study was conducted with two cohorts of in-service secondary mathematics teachers pursuing a master's degree in education (M.Ed) at a large state university in the Southeastern US. Data were collected from seven in-service teachers participating in a secondary methods course in Spring 2025 and eight in-service teachers enrolled in a middle school methods course in Fall 2025. Of these latter eight teachers, three were international teachers on professional leave, funded by their governments to pursue advanced training. Thus, all participants had teaching experience and were positioned to demonstrate a degree of agency in their practices.

Data Collection

The first group of teachers completed the *Perspectives about AI in Secondary Mathematics Teaching and Learning* (PAISMTL) survey, which included 12 items, nine of which were open-response (Sears, Castro-Minnehan et al., 2026). This survey was administered in class before the GenAI workshop. The teachers were asked to describe the extent to which they use AI to plan and teach lessons, which AI tools they use and how, and what ethical considerations they

employ. The participants were also asked to share their perspectives on using AI to support mathematics teaching and learning, on the extent to which AI can promote equitable learning outcomes, on the professional development they had received, and on the support teacher preparation programs should offer relative to AI.

The second group of teachers completed the *Ethics in AI in Mathematics Education* (EAIME) survey immediately following a workshop on ethics in AI in mathematics education (Sears, Castro-Minnehan et al., 2026). Of the 16 survey items, 13 were open-ended, asking teachers to share their perspectives on how ethical considerations related to AI integration affect teaching, learning, and assessment, to describe opportunities for teaching mathematics with GenAI, and to identify potential challenges and risks. The survey also asked teachers to share their views on how capable they feel of ensuring students' learning, discuss what they consider as evidence of learning when AI is used, outline the ethical rules related to GenAI use they want to establish for themselves and their students, contemplate the cognitive, physical, informational, and governance ethical dimensions of Ashok et al. (2022)'s framework, which was provided to them, and comment on what kind of professional support they might need to make ethical decisions regarding AI in mathematics education.

Data Analysis

The initial analysis of data from the PAISMTL and EAIME surveys provided valuable insights, indicating that teachers have polarized opinions on whether AI should be integrated into the mathematics curriculum (Sears, Castro-Minnehan et al., 2026; Sears, Franco et al., 2026). To better understand this phenomenon, we conducted a retrospective analysis of the open responses from both surveys, using the AIM-CEL Framework as an analytic lens. A retrospective analysis (Simon, 2019) occurs after data collection is complete and aims to inform models of individual thinking, social interactions, or instructional interventions, thereby extending initial interpretations of the data.

The first level of the retrospective analysis (Simon, 2019) involved a line-by-line analysis to identify instances of the phenomenon in question, here, the teachers' perspectives on integrating AI into the official, teacher-led, enacted curriculum, and the resulting impact on student learning outcomes. These perspectives, and how teachers envision they may evolve, shed light on teacher agency while also capturing factors that may contribute to AI integration. Thus, we imported the dataset into NVivo 15 (Lumivero, 2025) and coded it at the utterance level, capturing how various domains of the AIM-CEL Framework were appraised, using the following categories: *no AI use/AI-reluctant/AI-resistant,* and *AI-supportive/conscientious/ strategic intentional use*.

The *no AI use/AI-reluctant/AI-resistant* code reflected instances where the teachers acknowledged intentionally not using AI tools, actively avoided them, expressed distrust, skepticism, or concerns for negative implications on student learning (such as reducing cognitive rigor), expressed a preference for solely human activities or for limits or bans in the workplace and in policies, or expressed explicit reluctance toward AI integration into their curriculum. The code *AI supportive/conscientious/strategic intentional use* was applied when teachers acknowledged the intentional and purposeful use of AI tools, indicated being knowledgeable and responsive to the AI capabilities, described instances of integrating AI or facilitating discussions about it, and promoted ethical and appropriate use of AI. This code also captured teachers noting potential benefits of using AI and expressing a desire to enhance their own knowledge and instructional practices involving AI, while being conscious of the need for the human in the loop to verify the accuracy of AI-generated responses. After coding, matrices were generated to identify dominant codes and explore relationships among them.

For the second level of analysis, we considered the nature of teachers' understanding of AI, the extent to which they exhibited agency, and, potentially, its subset of epistemic agency. Thus, we scrutinized the codes, assessing the extent to which they suggested that teachers had agency in decision-making regarding AI integration across the curriculum. The third level of analysis aimed to develop explanatory constructs to account for how teacher perceptions may influence the nature of curriculum enactment in support of students' mathematical learning. We also identified factors that teachers perceived as supporting or hindering their use of AI.

Results

There were different views on the extent to which AI should be integrated into the mathematics curriculum. In the official curriculum, 5 codes expressed reluctance toward AI, while 15 codes supported the strategic and intentional use of AI. Regarding the teacher-led curriculum, 14 codes opposed using AI, whereas 34 supported it. In the enacted curriculum, 32 codes reflected a reluctant stance toward AI integration, while 69 supported it. Overall, 51 coded utterances reflected a negative view of AI integration (no AI, resistance, or reluctance), whereas 118 coded utterances supported incorporating AI across the official, teacher-led, and enacted curricula.

Nesting the utterances within the participants suggested that overall, teachers were more likely to support AI integration in the official, operationalized, and enacted curricula, although approximately one-third of the responses took a strong negative stance toward AI integration. We also identified factors that influenced the extent to which they use AI. The teachers demonstrated teacher agency and epistemic agency in some instances.

Teachers' Perspectives on AI Integration According to the AIM-CEL Framework

Official curriculum. Teachers who objected to AI integration in the official curriculum expressed concerns about data privacy and uncertainty about the details of AI operation. For instance, Teacher 1 explained,

> I am constantly concerned about how my data and the data of my students are being used. I also strongly believe in the concept of productive struggle. The over-dependence on these tools feels like the social contract between student and teacher has been broken; students are no longer obligated to work to learn. This is a problem. (EAIME)

Similarly, Teacher 13 noted, "I wouldn't encourage it currently, because I think there is a lot that is not fleshed out with how it is used in a math classroom. I think it is still too messy to use" (PAISML). The teachers' reasoning suggests that if AI integration in classrooms were to become a reality, more clarity is needed on data usage and AI tools, and on ensuring that all teachers are adequately prepared to use them.

Teachers who supported AI integration into the official curriculum reported using school guidelines and facilitating productive conversations with students. For instance, Teacher 3 indicated, "I am already having these conversations with students using the [district] guidelines" (EAIME), while Teacher 11 indicated that

> AI is here, and as teachers, we must stress the ethics and trust that students are doing what we ask as educators. We must also know how AI is being used and what we should be expecting for AI answers. (PAISML)

These teachers' remarks highlight students' role in the educational setting as critical partners rather than consumers, while also acknowledging the importance of clear expectations and guidelines for responsible AI use.

Teacher-intended curriculum. Teachers who were resistant to integrating AI into the teacher-intended curriculum were generally concerned about the repetitiveness and stagnation in AI-generated responses, as well as mathematical inaccuracies. However, some teachers simply preferred doing things the traditional way. For instance, Teacher 1 noted, "AI is notoriously bad at math. Until it improves, I am highly skeptical" (EAIME). Teacher 1 also noted, "I do not use it at all. I prefer to do my assignments the old-fashioned way" (EAIME). Other reasons for a reluctant stance included limited opportunities for teachers to learn about and experience using AI for instructional planning. For instance, Teacher 10 indicated, "I am not sure as I have not had time to sit and read/learn about using AI in planning and learning" (PAISML).

Teachers who supported using AI in the teacher-intended curriculum emphasized that AI tools can help them brainstorm, develop lesson plans, and communicate with stakeholders. For instance, Teacher 2 indicated, "Gen AI can help with lesson plans, communication with parents, [and] newsletters" (PAISML), while Teacher 3 noted, "I use it to brainstorm when I have not taught a subject before and to find resources for me to vet and consider" (EAIME).

Enacted curriculum. Resistance to AI integration into the enacted curriculum was grounded in the desire that classroom instruction should prepare students for assessments that do not currently include the use of AI, students may rely on the AI tool more than on the teachers, and students may not exhibit any effort to engage in mathematical tasks by treating AI as a "surrogate knower" (Jose et al., 2025). For example, Teacher 12 expressed this concern, saying, "Students think they don't need to learn ANYTHING [emphasis in the original] because AI can do it for them" (PAISML), while another teacher suggested that there is a need to "make exams offline, ask questions alive, ask them to present on their work" (Teacher 2, EAIME).

Teachers who support integrating AI into the enacted curriculum suggested that AI can be used strategically to verify the accuracy of students' responses, reflect on multiple problem-solving approaches, pose high-level questions, and engage in error analysis. Given the possibilities and opportunities that can be explored with AI, Teacher 8 indicated, "AI has so much power, but it's imperative that students are exposed to ethical use and taught how learning can be enhanced/expanded with it" (EAIME).

Student learning outcomes. All the teachers sought to promote student learning outcomes. Interestingly, both reluctance and support toward AI were motivated by teachers' desire to support students' mathematical learning. Teachers objecting to AI integration wanted to ensure that students did not become lazy, unable to demonstrate problem-solving skills, and overly reliant on AI tools. For instance, Teacher 2 noted, "This raises concerns about overreliance on AI, potential misinformation, and the loss of critical thinking and problem-solving skills if students depend too heavily [on AI]" (EAIME). Teachers who favor AI integration asserted that, if used responsibly, AI can support learning in and out of the classroom. For instance, Teacher 3 envisioned using AI as a personal tutor for students with limited financial means or limited access to technology outside the school, saying, "Students having a personal [AI] tutor seems like an amazing opportunity for students who cannot afford one. After [school] hours, they would still need the technology, which is not always possible" (EAIME).

Factors Teachers Perceive as Affecting AI Integration across the Curriculum

Various factors contributed to teachers' perspectives on AI across the mathematics curriculum. The factors included teachers' own knowledge and beliefs (23 coded instances), concerns for academic integrity and assessment (22 coded instances), access and equity issues (19 codes), understanding of AI tools (18 codes), teachers' own confidence and comfort level

with AI (15 codes), pedagogical considerations (8 codes), concerns for mathematical accuracy or AI hallucinations (7 codes), and students' attitudes and dispositions (6 codes).

Teachers' Perceived Agency in Integrating AI in the Curriculum

The results showed that teachers perceived having agency in determining whether and how to use AI. It was noted that teachers who were more willing to use AI reported receiving some professional development or training and felt more knowledgeable about AI tools. Additionally, several teachers exhibited *epistemic* agency in co-constructing knowledge and co-creating resources with AI. For instance, Teacher 15 noted,

> I think AI provides an excellent support role. I have used it to create a short reading quiz on an assignment, then refined the result with additional input. It was just as good as I would have made on my own, but it took minutes. As a teacher, my time is my most precious resource. I feel no guilt in using AI to support, but not to prevent myself from completing required learning. If I didn't understand a concept in my statistics class this fall, Copilot gave me a brief synopsis, and could elaborate and give me examples to try. I now understand the material, so I was not using AI to prevent learning, more to facilitate. (PAISML)

This quote illustrates how Teacher 15 exercised epistemic agency, using AI judiciously and responsibly. Such use of AI tools in the mathematics curriculum can increase productivity and promote efficiency in supporting learning.

Discussion and Implications

The results of the study align with prior research that suggests that teachers' perspectives of perceived benefits and constraints of AI may impact their willingness to integrate AI into their teaching practices (Albalawi, 2025; Ballenas & Lasco, 2025; Busuttil & Calleja, 2025; Chounta et al., 2022; Clarke, 2025; Egara & Mosimege, 2024; Korkmaz et al., 2025; Meylani, 2024; Sears et al., 2025; Sears, Castro-Minnehan et al., 2026; Walkington, 2025). Our contribution to this literature is the specification, through the AIM-CEL Framework, that AI integration spans all components of the mathematics curriculum: official, teacher-intended, and enacted, with implications for students' learning outcomes.

The study findings further show that teachers' reluctance to adopt AI or their support for it is expressed across all components of the AIM-CEL Framework. This indicates that teachers engage thoughtfully and deeply with the meaning and impacts of AI integration on society, the teaching profession, classroom interactions, and students' mathematical learning. Interestingly, both positive and reluctant attitudes toward AI integration were grounded in perceived benefits or negative impacts on student learning outcomes. This reveals complex connections between teachers' views of AI's advantages or risks and their ideas of what constitutes learning mathematics, whether it's demonstrating competencies on traditional assessments or developing flexible knowledge and reasoning skills. Although these relationships need further investigation, our findings underscore the importance of clarifying what it means to learn mathematics in an AI-enhanced curriculum and re-envisioning assessment strategies that effectively support AI integration, particularly to address concerns about how AI tools might influence cognitive rigor and students' demonstration of mathematical processes and practices.

Our findings also indicate that teachers can demonstrate both teacher agency and epistemic agency (a subset) regarding AI integration into the mathematics curriculum (Chu & Wang, 2025; Jose et al., 2025; Urbani, 2024). As AI continues to play an increasingly central role in education, it is essential for teachers to develop epistemic agency when engaging with AI and when involving students in these interactions. Therefore, our findings emphasize the importance

of supporting teachers in implementing AI-related policies and practices. Ongoing professional development is needed to increase the likelihood that teachers can implement AI strategically and responsibly, as well as to reflect on and address potential resistance to AI tools. Future research should examine changes in teacher agency and epistemic agency related to AI use across the mathematics curriculum following continued professional development.

In closing, we highlight that the AIM-CEL Framework can be used to examine how AI is integrated into the mathematics curriculum by helping researchers unpack the official, teacher-intended, and enacted curricula to promote student learning. The generalizability of our findings is limited by the relatively small sample of teachers from a single locale. Nevertheless, the findings provide insights into teachers' stances on "no AI" and on when it is essential to "know AI" to support mathematics teaching and learning.

DEVELOPMENT OF A MULTIDIMENSIONAL SURVEY OF UNDERGRADUATE MATHEMATICS STUDENT AND TUTOR REASSESSMENT EXPERIENCES

Despite growing use of reassessment in undergraduate mathematics, few validated instruments exist that measure the multidimensional experiences of students and tutors involved in reassessment. In this study, we developed a survey to explore motivational, affective, and cognitive dimensions of undergraduate student participation in reassessment from both students' perspective and that of the tutors responsible for preparing students for reassessments. Preliminary analyses of student and tutor responses at one southeast university provide evidence of survey item's reliability and content validity, although further analyses are needed to validate the survey.

Keywords: Assessment; Affect, Emotion, Beliefs, and Attitudes; Instructional Activities and Practices; Undergraduate Education

Reassessments, or exam retakes, in undergraduate mathematics courses, are typically discussed in the context of grading systems. While reassessment is often part of mastery-based, techniques-based, and standards-based grading, these grading systems also often include pre-defined topics that need to be mastered, retake opportunities on homework and other course assignments, and a grading scale based on number of topics mastered rather than percentage points (Cooper, 2020; Halperin, 2020; Harsy, 2020; Linhart, 2020). While the existing literature often reports positive outcomes for students participating in alternative assessments, much of this work relies on unvalidated instruments or researcher-generated surveys, and many studies fail to provide the survey tools, validation efforts, or instructor feedback (Hackerson et al., 2024).

The literature highlights a clear gap: a need for validated instruments to comprehensively assess student and tutor perspectives on reassessment. Accordingly, the purpose of this study is to develop two surveys measuring these perspectives, providing data that can inform refinement of the reassessment process, support potential scalability, and address gaps in the literature.

Context of the Study

This study is situated in the context of College Algebra and Intermediate Algebra courses at a university in the Southeastern US, where reassessment was implemented beginning in 2022. The primary goal of this initiative was to improve student success and persistence in high DFW gateway math courses. The reassessment structure was designed to emphasize more than grade recovery; students were required to complete remediation activities (such as worksheets and tutoring sessions) in the university mathematics tutoring center prior to retaking unit exams for the purpose of deepening their mathematics understanding. Courses were divided into 14 to 20 topics, allowing students to reassess individual topics following unsatisfactory performance on initial exams although the final exam could not be reassessed. Retakes were then coordinated with the center and returned to the instructor for grading. This context provides a unique opportunity to explore how both students and tutors experience reassessment, offering insights that could enhance the effectiveness of alternative assessment strategies in gateway mathematics courses.

In this study, reassessment is distinctive due to its wide-scale implementation across lower-level mathematics courses, its traditional exam structure, and its close integration with a mathematics tutoring center. This design helps reduce the remediation burden for instructors while supporting students who are working or commuting by providing flexible tutoring and reassessment timeslots. Figure 1 illustrates the reassessment process.

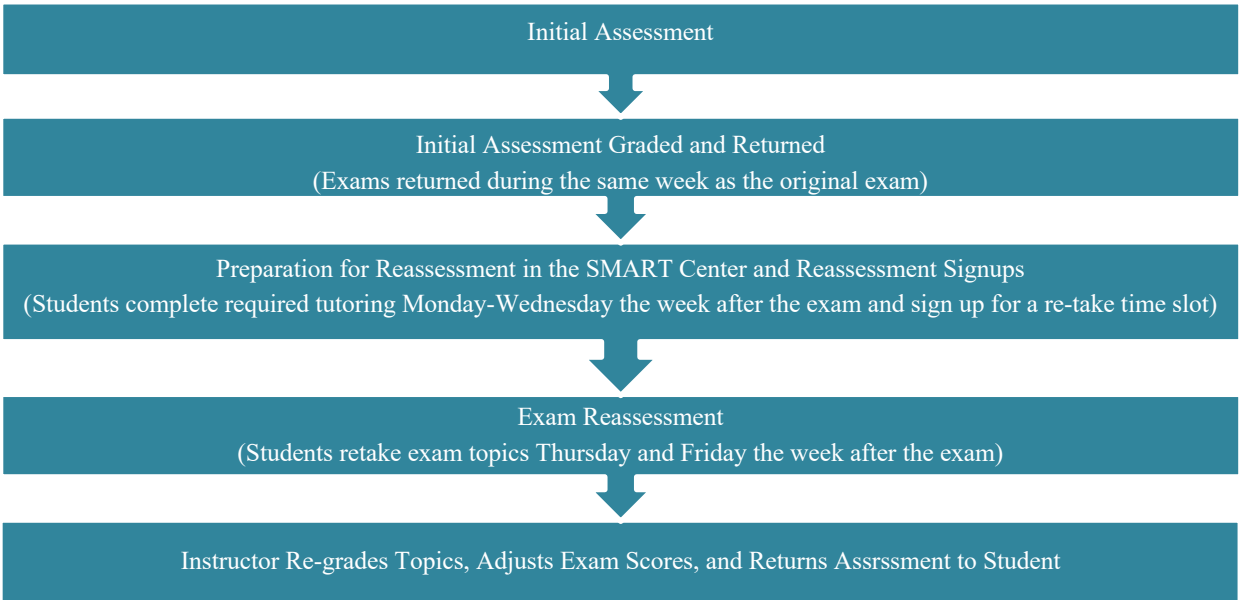

Figure 1: Student Reassessment Process

Conceptual Framework

The developed surveys measure constructs related to motivation and participation (i.e., how often students engage in reassessment and why), self-efficacy, self-regulation, anxiety, and program evaluation (i.e., how reassessments serve students and opportunities for improvement). Affective constructs, including self-efficacy, motivation, and anxiety, as well as attitudes and student behaviors, were selected based on their prominence and frequency in the existing literature (Hackerson et al., 2024). Prior research has also documented positive effects of reassessment on motivation, effort, confidence, and growth mindset (Barhite, 2024; Elsinger & Lewis, 2020; Harsy, 2020; Jones & Lanaghan, 2021; Mangum, 2020). These constructs are central to understanding the impacts of reassessment on both students and tutors. They inform potential modifications to increase participation, enhance buy-in, and improve the overall reassessment experience, ultimately supporting student success in lower-level mathematics courses. Figure 2 presents the conceptual framework, illustrating how reassessment influences motivation, participation, self-efficacy, self-regulation, and anxiety, which together shape students' perceptions of the initiative.

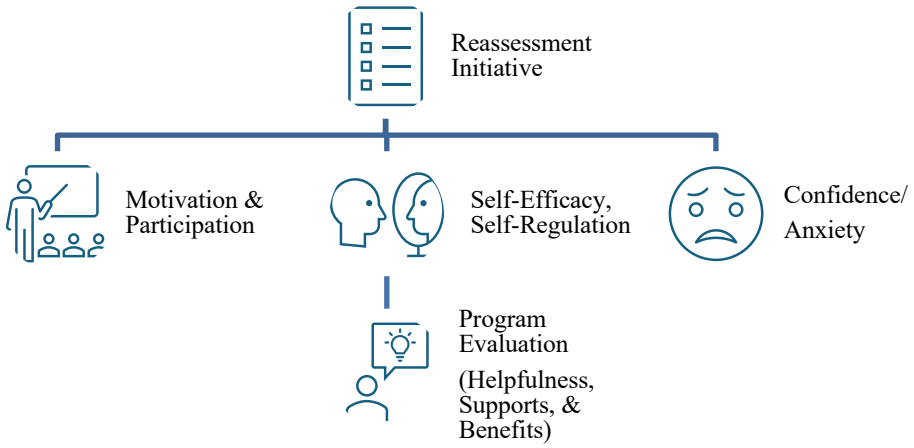

Figure 2: Conceptual Framework for Constructs

Methods

This study employed a quantitative approach to develop surveys aimed at capturing both qualitative and quantitative data on students' and tutors' perspectives of reassessments in lower-level college mathematics courses. Survey development followed the procedures outlined by Gehlbach and Brinkworth (2011) to support content and construct validity.

Instrument Selection

A systematic literature review of studies surrounding alternative assessment in college-level mathematics courses following the year 2014 was conducted. Forty-four studies were identified for inclusion in the literature review. Each study's outcomes and utilized instruments were noted. Furthermore, Hackerson et al.'s (2024) scoping review of alternative assessment practices in college-level STEM courses served as a helpful synthesis of existing survey tools.

Instrument Adaptation

Following the literature review, the Situational Motivation Sale (SIMS) and Mathematics Motivation Questionnaire (MMQ) were selected as the basis for questions measuring student motivation, self-efficacy, self-regulation, and anxiety due to their alignment with the desired constructs and availability. The Community College Survey of Student Engagement (CCSE) was selected as the foundation for the program evaluation component of the reassessment initiative due to its alignment with postsecondary education and the desired constructs. Questions from these existing surveys were compiled and adapted to fit the reassessment initiative.

While constructs were shared across the tutor and student surveys, questions on the tutors' survey relating to motivation, anxiety, and self-regulation focused on tutors' perceptions of how reassessments impact students. Program evaluation questions, in contrast, focused on tutors' own experiences, perceived benefits, and perspectives regarding the reassessment process.

Situational Motivation Sale (SIMS). The SIMS, which contained 16 items measured intrinsic motivation, identified regulation, external regulation, and motivation. The original Likert-scale design was maintained, while "not sure" or "not applicable" were added as options.

Community College Survey of Student Engagement (CCSE). Eight questions from the CCSE, a large community college evaluation survey, were adapted to fit the reassessment context and to avoid numerical labels in accordance with best practices (Gehlbach & Brinkworth, 2011). The remaining questions, which did not pertain to a classroom context, were not adopted.

Mathematics Motivation Questionnaire (MMQ). Fifteen of the MMQ items were included in the reassessment survey. The MMQ was shortened, and some similar ideas were removed to reduce the length of the reassessment survey. In alignment with survey best practices, the MMQ questions were altered from an agree/disagree Likert-scale format to an amount/frequency Likert-scale format (Gehlbach & Brinkworth, 2011).

Once compiled, a Qualtrics survey was developed and adjusted for flow. The student survey was adapted with minor adjustments to measure tutors' perspectives. Following the revision of selected items, both surveys were examined by content experts to establish content validity.

Content Expert Review

Three content experts were consulted to ensure content validity for both tutor and student surveys. Experts were selected based on their experience with reassessment and their familiarity with the reassessment process. They were asked to review each survey item for appropriateness and clarity, provide feedback on question wording, and suggest additional elements to include. Expert A is an instructor with extensive experience teaching College Algebra courses using reassessment. Expert B serves as the director of the mathematics tutoring center responsible for preparing students and administering reassessments. Expert C is a doctoral student and College Algebra instructor who also teaches courses utilizing reassessment. Each expert received links to both surveys and met in person with the researcher to provide feedback.

The feedback from content experts resulted in revisions to question wording and response scales to enhance clarity and reduce complexity. Experts also recommended removing items related to enjoyment of mathematics, adding "please explain" prompts to free-response questions, and including items assessing how reassessment supports students in managing responsibilities across other courses. All recommendations were incorporated into both the student and tutor surveys. Following the content expert review, cognitive interviews were conducted with both students and tutors to further refine the instruments.

Cognitive Interviews

Student cognitive interviews. Cognitive interviews were conducted with six students who had completed a reassessment in a College Algebra course within the past year. Students met with the researcher and were asked to answer each question aloud, describing their thought process behind answering the question. Additionally, students were asked if there is anything else they feel should be included in the survey. Iterative improvements were made and tested with subsequent participants.

Insights from the cognitive interviews led to several changes including adding definitions or rewording for clarity and the inclusion of a free-response question asking what motivates students to participate in reassessment. Following cognitive interviews, all suggested revisions were incorporated. Additionally, questions which were misleading were re-worded to ensure answers were in line with those desired.

Tutor cognitive interviews. Cognitive interviews were conducted with three mathematics tutoring center tutors. These tutors, a mix of undergraduate and graduate students, were selected based on their role, length of employment with the mathematics tutoring center, and familiarity with the reassessment preparation and proctoring process. Tutors were also asked to answer the survey out loud while including their thought process behind their answer and to provide feedback on the clarity of questions and any additional questions they felt should be added.

Several common themes emerged from the interviews, including recommendations to split lengthy questions and revise wording for clarity, adjust numerical intervals on two items, and add questions addressing how reassessment promotes better study habits, clarifies tutor roles, and

reflects support from administration. Iterative revisions were made following each interview, and when appropriate, parallel changes were applied to the student version of the survey.

Instrument Pilot and Refinement

Following cognitive interviews, tutor survey was distributed to all mathematics tutoring center tutors via the center's GroupMe page. Within the first day, four responses were received. One tutor participant reported confusion regarding the wording of a particular question. Based on this feedback, the question was revised and split into two separate items. Although this modification resulted in the loss of a small portion of previously collected data for that question, all other data remained intact, and the survey was improved for clarity for future respondents.

The revised survey was subsequently redistributed to tutors via Canvas at the end of the Fall 2025 semester and the beginning of the Spring 2026 semester, yielding additional responses. Students were invited by proctors to participate after completing their third exam retake. Upon collection of survey responses, data was analyzed to assess internal consistency and reliability.

Results

Forty-five tutors were invited to participate in the survey via a Canvas announcement in the Fall 2025 and Spring 2026 semesters and 40 consenting responses were collected. To track repeat responses, tutors were asked to provide the last four digits of their phone number. In cases where a tutor submitted multiple responses, only the most recent submission was retained for analysis.

Approximately 100 students who participated in the third exam reassessment were asked to take the student perception of reassessment survey. 57 students engaged with the survey by scanning the QR code. Following the removal of fully incomplete surveys, 20 complete responses were recorded, and 25 partial responses were gathered.

Following cleaning of data, results were exported into R (R Core Team, 2024) for analysis and mean and standard deviation were collected for each item.

Tutor Perspectives of Reassessment: Internal Consistency and Descriptive Data

Table 1 displays each Likert-scale question and the corresponding participation rate and standard deviation. Based on information gathered from the survey, two questions were altered to add a sixth Likert-scale option.

Table 1: Likert-Scale Items - Tutor Perspectives

Construct	Number of Responses	Question Type	Mean Range	Standard Deviation Range
Motivation	40	Likert (6-point scale ranging from Not At All–Very Much) 5 Questions	3.34–4.9	0.99–1.71
Perceived Course-Related Benefits	38	Likert (5-point scale ranging from Not At All–Very Much) 5 Questions	3.21–4.51	0.96–1.56
Self-Regulation	38	Likert (6-point scale ranging from Not At All–Very Much) 4 Questions	3.27–4.08	1.21–1.63
Confidence	38	Likert (6-point scale ranging from Not At All–Very Much) 4 Questions	3.49–4.41	1.36–1.69

Anxiety	38	Likert (6-point scale ranging from Not At All–Very Much) 4 Questions	3.26–4.20	0.98–1.50
Perceived Impacts on Learning Outcomes	38	Likert (6-point scale ranging from Did not Emphasize–Emphasized Very Much) 6 Questions	2.25–3.14	1.20–1.56
Perceived Level of Challenge	38	Likert (6-point scale ranging from Did Not Challenge–Challenged Very Much) 1 Question	3.10	1.64
Perceived Student Support	38	Likert (6-point scale ranging from Did Not Emphasize–Emphasized Very Much) 6 Questions	2.27–3.86	1.33–1.65
Perceived Long-Term Benefits and Growth	38	Likert (5-point scale ranging from Contributed Very Little–Contributed Very Much) 5 Questions	1.37–1.43	2.19–2.86

Although many statements exhibited high variability, this was expected due to the opinion-based nature of the items. Free-response question responses at the end of the survey further contextualized this variability, with some tutors expressing positive views of reassessment and others noting challenges. Therefore, the observed variability in opinion-based items is reasonable and does not indicate a need for item revision.

Table 2: Cronbach's Alpha and McDonald's Omega Values - Tutor Perspectives

Construct	McDonald's Omega	Cronbach's Alpha
Motivation	0.89	0.81
Perceived Course-Related Benefits	0.96	0.92
Self-Regulation	0.93	0.92
Confidence	0.88	0.83
Anxiety	0.81	0.53
Perceived Impacts on Learning Outcomes	0.96	0.93
Perceived Student Support	0.91	0.86
Perceived Long-Term Benefits and Growth	0.96	0.94

Table 2 presents alpha and omega values for each construct. All values were high enough to suggest good internal consistency except for the alpha value relating to the anxiety construct. In this case, the low alpha value was likely due to violations of tau-equivalence, and the omega indicated acceptable internal consistency.

While 40 responses is a relatively large response rate given a lack of incentive for completion and the small population size, the small sample size impacted McDonald's Omega values. Factor-based reliability estimation produced diagnostic warnings for four constructs (motivation, anxiety, confidence, and self-regulation), likely due to this small sample. As a result, McDonald's omega values were interpreted alongside Cronbach's alpha. As new tutors are added and the sample size grows, further analysis will be conducted.

Student Perspectives of Reassessment: Internal Consistency and Descriptive Data

Table 3 displays each construct along with its number of responses and standard deviation in response for each item.

Table 3: Likert-Scale Questions - Student Perspectives

Construct	Number of Responses	Question Type	Mean Range	Standard Deviation Range
Motivation	39	Likert (6-point scale ranging from Not At All–Very Much) 5 Questions	2.62–4.69	0.51–1.88
Perceived Course-Related Benefits	35	Likert (5-point scale ranging from Not At All–Very Much) 5 Questions	3.91–4.47	0.79–1.11
Self-Regulation	33	Likert (6-point scale ranging from Not At All–Very Much) 4 Questions	3.85–4.30	0.65–1.05
Confidence	24	Likert (7-point scale ranging from Not At All–Very Much) 4 Questions	4.00–4.20	0.79–1.1
Anxiety	24	Likert (7-point scale ranging from Not At All–Very Much) 4 Questions	3.68–4.05	0.69–1.22
Perceived Impacts on Learning Outcomes	26	Likert (6-point scale from Did not Emphasize–Emphasized Very Much) 7 Questions	1.96–2.79	0.81–1.42
Perceived Level of Challenge	28	Likert (6-point scale ranging from Did Not Challenge–Challenged Very Much) 1 Question	2.64	1.29
Perceived Student Support	27	Likert (6-point scale from Did not Emphasize- Emphasized Very Much) 6 Questions	2.44–2.89	1.45–1.77
Perceived Long-Term Benefits and Growth	26	Likert (6-point scale from Did Not Contribute–Contributed Very Much) 6 Questions	2.31–3.31	1.29–1.56
Intended Future Use	25	Multiple choice with 3 options 1 Question	1.96	0.34

The variability of survey responses was likely due to the "not sure" option as well as differing opinions of reassessment. Students were unanimous in their opinion that reassessment was helpful because it improves grades. But some students felt that reassessments were great as-is, while others mentioned it was too easy, possibly explaining why such great variation existed for the level of challenge construct. Table 4 displays alpha and omega values for each construct.

Table 4: McDonald's Omega Values - Student Perspectives

Construct	McDonald's Omega	Cronbach's Alpha
Motivation	0.64	0.36
Perceived Course-Related Benefits	0.94	0.86
Self-Regulation	0.89	0.87
Confidence	0.77	0.61
Anxiety	0.90	0.75
Perceived Impacts on Learning Outcomes	0.92	0.87
Perceived Student Support	0.97	0.93
Perceived Long-Term Benefits and Growth	0.97	0.92

The alpha values for motivation and confidence were small, as shown in table 4. While this suggests poor internal consistency under the assumptions of Cronbach's alpha, alpha can underestimate reliability when the tau-equivalence assumption is violated. Because the included items may measure different aspects of the construct, McDonald's Omega was also examined. The McDonald's Omega value for both constructs is much higher, suggesting that both constructs have an acceptable internal consistency.

All other constructs included in the instrument that utilized a Likert-scale had good internal consistency according to both the alpha and omega values. While this suggests internal consistency for the instrument, the sample from which data was collected was small. Each item ranged from 25 to 39 responses. While the data preliminarily suggests reliability and internal consistency, a larger sample is necessary to draw concrete conclusions.

Conclusion

In this study, we developed surveys to measure student and tutor perspectives of reassessment. Information collected on the survey included mostly Likert-scale questions, with additional free-response and demographic questions to further understand perspectives and gather feedback. Both instruments were examined for content validity via content experts. Cognitive interviews were conducted with tutors and students, resulting in iterative changes to both instruments. Following cognitive interviews, both surveys were disseminated to mathematics tutoring center tutors and reassessing College Algebra students.

Using classical test theory, analyses indicate the survey items show promise for further refinement. Future studies include gathering additional responses for factor analysis. Future item refinement will focus on separating program-evaluation items from items evaluating affective latent constructs relating to the concept of reassessment in undergraduate mathematics.

Given increasing gaps in prerequisite skills necessary for success in undergraduate mathematics courses, reassessment structures that promote student success and persistence are essential. However, these structures cannot be developed by faculty and administration in isolation. The voices of students and tutors are essential in meeting the aims of these reassessment initiatives and increasing the likelihood of student participation and deeper mathematics learning.

This study addresses a critical gap in reassessment research by providing empirically grounded instruments to measure student and tutor perspectives. These tools can inform both local program improvement and broader research with the goal of designing equitable, learning-centered reassessment systems.

As teachers interact with textbooks and other curricular materials to plan instruction, they rely heavily on their curricular reasoning (CR) to make decisions regarding what tasks and problems to use in their mathematics lesson. Teachers' CR may include a number of aspects focusing on differing components of the classroom environment. To assist teachers in considering these various CR aspects, we developed a self-assessment survey to help teachers in instructional planning and enacting lessons. In this paper we describe the development of this survey, the process by which the survey was validated, and consider how the survey can be used to impact teacher practice.

Keywords: Curriculum, Instructional Activities and Practices, Teacher Beliefs, Research Methods

Teachers and students learn from a variety of mathematics curricula, and teachers use these curricula in numerous ways as they plan and enact instruction. Different types of curricula provide various opportunities for students to learn mathematics (e.g., Tran et al., 2016; Tarr et al., 2008). Teachers also use curricula differently depending on the context (e.g., Remillard & Kim, 2017). However, little is known *about teachers' cognitive work as they use mathematics curriculum to plan and enact lessons*. This cognitive work includes making myriad mathematical decisions and reasoning as they plan and enact lessons with curricula. Roth McDuffie and Mather (2009) defined teachers' curricular reasoning (CR) as "a specific form of pedagogical reasoning that teachers employ while working with curriculum materials to plan, implement and reflect on instruction" (p. 303). As teachers utilize a variety of curricula, they act on many decisions including the degree to which the curriculum provides students the opportunity to learn targeted mathematical content, and whether it is at the level needed to meet learning goals. Investigating teachers' CR can elucidate why teachers make specific mathematical decisions such as skipping or reordering lessons, revising tasks, or modifying definitions. While some decisions may appear to an observer as inappropriate for a given situation, these decisions may be much more complex than simply correct or incorrect. In understanding teachers' reasoning behind decisions, teachers can be better equipped to deliberately make productive decisions and strengthen or avoid decisions that lead to less productive outcomes for teaching and learning.

In this paper we share results regarding the development process for a survey to assist teachers in considering various CR aspects in their instructional planning. We describe how we partnered with teachers in the development process, provide survey results from teachers who have used the survey across the four states, and amplify teachers' voices in how the survey assisted them reason through mathematical decisions as they plan, enact, and reflect on their teaching. The development of this survey was part of a larger NSF-funded project *Quantifying*

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Curricular Reasoning as a Critical Practice in Teaching Mathematics (Grant Nos. 2201164, 2201165, 2201167, 2525831, and 2201169). The goal of the project is to design and validate tools for middle school mathematics teachers to use to identify and quantify their CR. The survey is one of these tools and is aimed at formatively assessing and providing feedback to teachers on their use of CR as they plan and enact mathematics lessons.

Cohen et al. (2003) introduced the Instructional Triangle to depict the interactions among teachers, students and the mathematical content in the classroom. However, given the different representations of, and approaches to, mathematical content seen in mathematics curricula, we argue that the mathematical content should be two distinct classroom elements to reflect two qualitatively different components (i.e., the Mathematics and the Curriculum) that impact the classroom learning environment. Building on the Instructional Triangle (Cohen et al., 2003) our team developed the Instructional Pyramid (Dingman et al., 2021; Teuscher et al., 2025), as shown in Figure 1, to depict the interaction among four major classroom elements (i.e., Teacher, Student, Mathematics, Curriculum). Each edge of the pyramid represents one of the six key CR aspects that teachers reason with as they plan, enact, and reflect on their mathematics lessons. Table 1 lists operational definitions for each CR aspect. The self-assessment survey developed in our project unpacks the six CR aspects for teachers and instructional coaches to identify which of these CR aspects teachers use and which ones they may want to develop further. Initial findings from our pilot work with the survey indicate that when teachers reason with all CR aspects on the Instructional Pyramid, they provide their students with learning opportunities that enhance student learning.

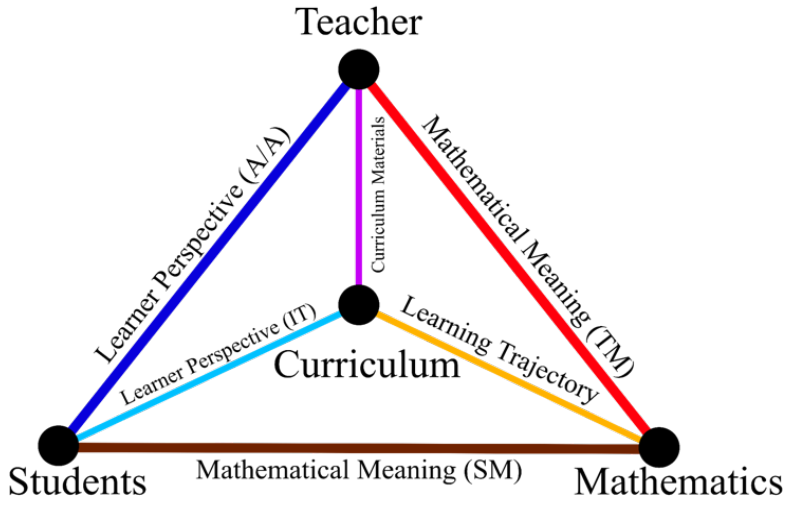

Figure 1: Instructional Pyramid with Curricular Reasoning Aspects

Table 1: Aspects of Mathematics Teacher Curricular Reasoning Operationally Defined

CR Aspect	Operational Definition
Viewing Mathematics from the Learner Perspective – Anticipating and Assessing (LP-AA)	Teachers "reason about the specific details of the mathematics or structure of the lesson to consider student interpretations of the mathematics, anticipate how students will perform or perceive the mathematics in the lesson, or identify student misconceptions that will need to be addressed as the lesson progresses" (p. 276).
Viewing Mathematics from the Learner Perspective – Intentionality of Tasks (LP-IT)	Teachers "reason about the intentionality of the task (IT), suggesting that teachers have a well-defined purpose for giving students specific questions or tasks that will guide them in learning the mathematics concepts that are intended" (pp. 276-277).
Mapping Learning Trajectory (LT)	Teacher "reasoning about how the mathematical concepts will unfold in a lesson or how the mathematics of the current lesson connects to past or future topics" (p. 274).
Considering Mathematical Meaning – Students (SM)	"…centers on what the teacher thinks students should understand (SM) based on the teacher's own mathematical meanings" (p. 278)
Considering Mathematical Meaning – Teachers (TM)	"…teachers' reasoning with their schemes for how they understand the mathematics under study" (p. 278).
Analyzing Curriculum Materials (CM)	Teachers "analyze or compare curriculum materials to other materials, providing analyses of the strengths and limitations of the competing materials and offering details of the various approaches" (p. 273).

Note. Operational definitions directly quoted from Dingman et al., 2021.

While much of the research around curriculum use has focused on in-depth interviews with individual teachers using a particular curriculum, as well as a labor-intensive qualitative analysis to determine how teachers use these specific curricula, our project pursued developing a tool that is valid and reliable, and usable for many teachers, regardless of their mathematics curricula. Therefore, this survey allows teachers to work with other colleagues to improve their decision making.

Development and Piloting of the CR Survey

Building on our prior work delineating the six CR aspects shown in Table 1, the survey development began with forming teams within our project personnel and outlining key items for each of the CR aspects. Three teams were assigned two CR aspects each and used existing definitions for the CR aspects as well as data from previous teacher interviews (Dingman et al., 2021) to draft the items of each aspect to guide survey item development. After several rounds of internal revisions, the list of survey items was sent out to external reviewers for additional input to inform *content validity evidence*. In total, 97% of items were identified as aligned with their CR aspect by the Expert Panel. Before moving into field testing with typical participants, survey language was modified based on expert panel review information.

We further refined the survey by conducting four rounds of cognitive interviews with 12 middle grades teachers, followed by administering the survey through three pilot studies with larger teacher samples across seven states. Each round informed revisions to survey items, language for items and instructions, and response scale, resulting in a final 38-item survey. At the start of the cognitive interview, teachers were asked to consider a mathematics lesson they taught within the past two weeks as they answered the items in the survey. Each teacher was asked to read the survey items aloud and to answer according to their experience planning the lesson under consideration. Teachers were also asked to comment on the introductory narrative, the survey response scale, and the demographic information collected on the survey. Information collected from cognitive interviews informed *response processes validity evidence* and *consequences of testing validity evidence*. Across aspects, 11 of 12 (92%) teacher participants indicated feeling no negative consequences related to completing the survey and all participants (100%) noted being able to use the survey scale well.

After the four rounds of teacher cognitive interviews, we administered the survey through three pilot studies with groups of middle grades mathematics teachers to see how the items were capturing teachers' CR. The pilot studies focused on establishing survey validity and removing items that were redundant. Teachers were invited to complete the survey in a manner consistent with how we anticipated teachers may interact with the survey, namely as a reflection upon a past lesson they had taught and the instructional planning methods they used to create and enact that lesson. The first two pilot studies included 103 and 184 middle grades mathematics teachers, respectively, from the four states represented in the project. The third and final pilot study used email contacts and popular listserv connections to invite teachers nationally to complete the survey. A total of 219 mathematics teachers across seven states responded to the survey. The results of these pilot studies are summarized in the next section, which details the evolution of the survey across the four rounds of pilot studies.

Evolution of CR Survey Based on Quantitative Field-Testing

At the conclusion of the teacher cognitive interviews, the CR survey consisted of 61 items across the six CR aspects. One of the goals of the pilot studies was to identify items that were duplicative in terms of consistently reporting the same results across teachers. Based on the Rasch rating scale model (Andrich, 1978) results of the first pilot study, we removed 15 items from the survey due to redundancy in content and difficulty measures. In addition, we adjusted the language of several items based on item fit statistics, while the data strongly indicated the 4-point response scale was functioning well across all aspects and should be maintained.

Given the large reduction in items from the first pilot study, a second pilot study was conducted prior to the national pilot study with teachers from across the four states represented in the project as well as teachers from one additional state recommended by the project staff (five states total). Rasch results of the second pilot study reflected those of the first pilot study in relation to the effectiveness of the four-point scale in the survey. No item language adjustments were recommended as a result of the second pilot study, as all items fit well in their respective aspects. Finally, important psychometric findings led to extensive team discussions centering on the meaning of the CR construct produced several policy-, evidence-, and theory-informed item removal decisions. We removed all four items in the survey related to "race, ethnicity, culture, language and family" due to federal policy changes regarding research related to racial, ethnic, and cultural diversity. Additionally, we removed one item related to facilitating student engagement and two items related to connecting mathematics to students "everyday lives" due to psychometric and conceptual redundancy.

The national pilot study resulted in one additional item being removed from the survey due to redundancy. Across pilot studies, 23 items were removed, reducing the survey by 37.7% to 38 items. Rasch analysis indicated strong *response processes validity evidence* in alignment with Linacre's (2002a) guidelines for optimizing the effectiveness of rating scales. Each scale category had 10+ observations. All measures advanced suggesting participants with higher rating combinations produced higher measures. And outfit mean-squares (MNSQ) were all lower than 2.0, indicating appropriate randomness in the data. Across the six aspects and overall, *internal structure validity evidence* was also strong according to well-documented standards (Duncan et al., 2003; Linacre, 2002b). Rasch reliability for persons (range 0.70–0.92) and items (range 0.95–0.99) as well as separation (persons range 1.53–3.33; items range 4.39–9.21) were all acceptable or higher. No items misfit in a manner that would degrade the measure (all items < 2.0 MNSQ). And all items had positive point-biserial values suggesting they well fit within their respective aspects and the overall CR construct. Figure 2 is the complete variable map for all the items in the Curricular Reasoning Self-Assessment Survey Suite (CR-SASS) based on our pilot studies. This map identifies items that are more likely to be thought about and influence teachers' lessons (e.g., those near the bottom of the ruler) as well as those items that are more difficult for teachers to reason with (those near the top of the ruler). We also can create individual variable maps to identify the items within the six CR aspects that are more difficult and easier for teachers to reason with as they plan and implement their lessons.

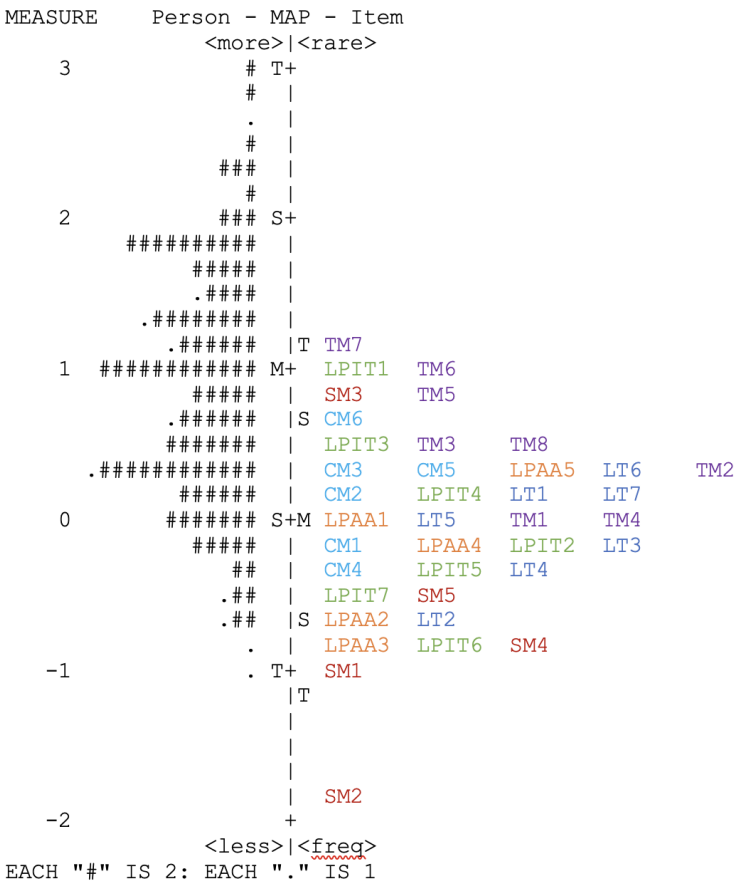

Figure 2: Variable Map with All CR-SASS Items

The Curricular Reasoning Self-Assessment Survey Suite (CR-SASS)

The resulting CR survey consists of eight sections that capture information about the lesson that teachers planned, demographic information on the teacher, and the extent to which the teacher considered various items of the six CR aspects in their instructional planning for the given lesson. In the initial section, teachers consider a mathematics lesson they planned and taught within the last two weeks. Teachers are instructed to select a lesson that was not the first or last lesson of a particular unit, as well as a lesson that encompasses the teacher's typical instructional practice. For the purposes of the survey, a lesson can last for a minimum of one day or can be a multi-day lesson. Teachers provide the title of the lesson, the grade level(s) of the students completing the lesson, the type of class (i.e., Honors/Accelerated/Gifted, General/Regular/On-Level, Co-taught/Remedial/Extra Support, or Other), the length of the class period in which the lesson will occur, the mathematical domains for the lesson, and the overall lesson duration. Teachers also provide information regarding how many years they have taught this specific lesson prior to this year and if there are other mathematics teachers who they have discussed or planned with for this lesson.

The teacher then answers a series of items for each of the six CR aspects outlined in Table 1. For purposes of space as well as ongoing efforts to finalize the survey, only a portion of the survey is included. Figure 3 below includes the survey items that teachers complete for the Learner Perspective: Intentionality of Tasks (IT) section of the survey along with the rating scale.

Learner Perspective: Intentionality of Tasks

To what extent did you think about the mathematical activities while planning and teaching this lesson this year or in past years?

I thought about:	I **did not think** about this for this lesson.	I thought about this, but it **did not influence** this lesson.	I thought about this, and it **influenced** this lesson.	I thought about this, and it **strongly influenced** this lesson.
1. **Selecting** manipulatives (fraction bars, cubes, 3-D solids, or online versions of manipulatives) to support my students' learning while working on activities.	○	○	○	○
2. **Selecting** activities to support my students in applying mathematics strategies.	○	○	○	○
3. **Modifying** activities to connect mathematics to my students' everyday lives.	○	○	○	○
4. **Modifying** activities to support my students' explorations of mathematics concepts.	○	○	○	○

5.	**Modifying** activities to meet my students' need**s** for learning mathematics.	○	○	○	○
6.	Structuring participation (independent, pairs, small groups, and whole class) in mathematics activities to support my students' learning while working on activities.	○	○	○	○
7.	Facilitating discussions about mathematics to support my students in sharing their thinking during activities.	○	○	○	○

Figure 3: Survey items from the Learner Perspective: Intentionality of Tasks (IT) section

In each CR section, teachers consider the extent to which the given items were considered and influenced the lesson under consideration. The items provide a range of considerations under each CR aspect that allows the teacher to reflect on each CR aspect in their overall instructional planning.

After the teacher completes the six sections corresponding to the CR aspects, a final section of the survey collects demographic information on the survey respondents. In addition to documenting the teacher's gender, race/ethnicity, and highest level of education, survey respondents provide the number of years of teaching experience they possess, the number of years teaching mathematics, whether or not they have a current teaching license in their grade level, the state in which the teacher works, the type of school where the teacher works (i.e., charter, private, public, other), and the geographical region in which the teacher works (i.e., rural, suburban, urban, other).

Conclusion

Prior to the development of the survey there was not a way for teachers to measure their own CR. We knew we needed to find an efficient process for providing teachers feedback on their CR. The CR survey provides teachers with a practical, formative tool to assess and strengthen their CR. By making teachers' decision-making visible, the survey encourages reflection, informs instructional adjustments, and ultimately supports richer student learning opportunities. As the first validated quantitative measure of CR, the survey extends research beyond qualitative studies and offers a scalable approach to improving mathematics instruction.

We have also found that while working with teachers involved in the cognitive interviews, these teachers reflected on their own teaching without being prompted. In some cases, teachers stated, "I have never been asked to think about this [an item] in my teaching." Therefore, the survey can provide immediate feedback to teachers without having a research person there to guide the conversation.

We think that teachers and instructional coaches will be interested in seeing and using the survey to measure teachers' CR. We also believe that once teachers use the survey, they will continue to do so in the future in ways that will promote learning and will improve their CR, which will affect their students' learning of mathematics concepts.

CR in mathematics is a practice that has only been studied qualitatively (Bostic et al., 2022; Dingman et al., 2021). Therefore, the development of quantitative measures and instruments will create broader reach in terms of practical, economical, and efficient data collection (Creswell, 2008). The survey is one part of our broader work to link research on teachers' CR with the development of tools to formatively assess teachers' CR and sharing how the tools are used by teachers in the field. By introducing the survey to classroom teachers, these teachers have the opportunity to not only learn about CR, but they also can utilize the survey to strengthen their overall curricular decision making. Our goal in developing the survey is to assist teachers in becoming aware of their CR so they may expand their reasoning, which we hypothesize can change students' opportunities to learn mathematics.

EXPLORING EQUITY AND PEDAGOGICAL CONSIDERATIONS OF ELEMENTARY TEACHERS' MATHEMATICS CURRICULAR USE: VISION AND TRUST

Doris Fulwider

Elementary teachers navigate a multitude of curricular resources and local curricular-use policies to design and implement engaging and equitable mathematics learning experiences for their students. Drawing on interview data, we investigated how elementary teachers used available curricular resources to enact their curricular visions, specifically regarding effective instructional approaches and equitable learning opportunities. Findings highlighted the complexity of teachers' mathematics curricular decision making as they strive to meet the needs of their diverse students. The findings also revealed how vision and trust mutually reinforce one another. We discuss the relationship between available curricular resources and teachers' curricular vision and conclude by suggesting next steps to support their work in the mathematics classroom.

Keywords: Curriculum, Elementary School Education, Instructional Vision

Frameworks

We draw on Breyfogle and colleagues' (2010) curricular reasoning framework, with particular attention to curricular vision and trust. They define curricular reasoning as "the thinking processes that teachers engage in as they work with curriculum materials to plan, implement, and reflect on instruction" (p. 308) and frame these processes as the interaction among curricular knowledge, vision, and trust. Curricular vision is knowing the path of learning, specifically where students have been, where they are now, and where they need to go, along with the knowledge of how to get them there (Darling-Hammond et al., 2005). Such vision involves a sophisticated understanding of mathematical coherence—the interconnectedness of mathematical concepts and ideas—and effective teaching strategies to help students see those connections (Drake & Sherin, 2009). With such understanding, teachers make conscious, purposeful decisions about what to teach, in what order, and how to teach it for understanding. Beyond the mathematical considerations, curricular vision also involves attending to the social, emotional, and educational needs of students, both as individuals and as a community of learners, as well as understanding the social aspects of education to successfully navigate local, state, and national policies, parent and community interactions, and their own assumptions, beliefs, and values about the educational process (Darling-Hammond et al., 2005). Drake and Sherin (2009) posit that as teachers understand a curricular resource, they can decide whether they trust it to satisfy their vision, either as written or with modifications. In the process of becoming familiar with curricula and making those decisions, curricular trust and vision support and reinforce one another's development.

Relevant Literature and Purpose

Elementary teachers use a range of curricular resources to teach mathematics, including district- and school-mandated curricula and supplemental materials (Sapkota et al., 2024). Consequently, they engage in curricular reasoning when interacting with these resources, deciding which to use and how to use them (Breyfogle et al., 2010; Dingman et al., 2021; Tran & O'Connor, 2024). These interactions occur within teachers' institutional, political, and pedagogical contexts, which shape how they negotiate curriculum mandates, available resources, and pedagogical choices (Tran & O'Connor, 2024). For example, Dingman and colleagues (2021) suggested that middle school teachers continually weigh whether materials align with standards, provide coherent mathematics instruction, facilitate student interpretation, promote mathematical understanding, and fit the classroom context and content.

Because elementary teachers in the United States are grade-level generalists responsible for students' success across multiple subject areas, their curricular decision-making processes and associated curricular vision may differ from those of subject-specific secondary teachers and thus warrant further investigation. Teachers not only intentionally select resources that align with their vision, but the availability of resources also shapes how their curricular implementation unfolds. For example, Siuty and colleagues (2018) suggested a bidirectional relationship between curricular availability and teachers' beliefs, noting that "a curriculum facilitated middle school teachers' decision-making around individualizing instruction" (p. 39). Building on this research, we became interested in examining how elementary teachers' curricular vision is informed by the curricula they use and, conversely, how it is guided by available resources. In this paper, we answer the following research question: How do elementary teachers use available mathematics curricular resources to enact their curricular vision?

Methods

Participants and Data

This study is part of a larger project aimed at understanding elementary teachers' mathematics curricular decision-making processes. The data for this study came from a three-phase interview with five elementary teachers at a Midwestern school. The teachers' pseudonyms are Audrey (2nd grade), Kasie (3rd grade), Jamie (4th grade), Mary (3rd grade), and Sarah (2nd grade). The first two interviews were individual, and the third was a focus group with all five teachers. In these interviews, we asked teachers which resources they used, whether they were mandated or supplemental, who mandated them, and how much control they had over their implementation. We also asked how they established curricular coherence across multiple resources, what challenges they faced in implementing curricular resources, how they collaborated with one another, and what support they needed in the process. One teacher reported using as many as 14 curricular resources to teach mathematics, and the others used at least eight. Across teachers, the most frequently used resources included DreamBox, enVision Math, FlashToPass, IXL, Pinterest, Study Island, Super Teacher Worksheets, Teachers Pay Teachers (TPT), XtraMath, and resources they designed themselves. EnVision Math was the district's core mathematics curriculum; however, only some of the teachers reported that its use was mandated. All five teachers reported that the district mandated the use of DreamBox, and one teacher reported that the school mandated IXL. All but one of the teachers reported having "complete," "a lot," or "quite a bit" of control over their curricular use. The teachers indicated which resources they trusted or distrusted for various purposes, depending on how well aligned those resources were with their curricular vision.

Data Analysis

In the first coding cycle, we used iterative rounds of deductive and inductive analysis (Saldaña, 2016) to identify instances in which teachers discussed their mathematics curricular vision in relation to curricular trust. We began with definitions of curricular vision from the extant literature and generated a set of initial visions (deductive) that teachers might express. We then refined those codes based on what we found in the data (inductive). For example, drawing on the definition of curricular vision as knowing the path of learning—where students have been, where they are now, and where they need to go, along with the knowledge of how to get them there (Darling-Hammond et al., 2005), we created the code: "vision about effective instructional approaches for implementing resources to develop students' mathematical understanding." As we coded for instances of curricular vision, we noticed that teachers frequently discussed trusting or distrusting curricular resources in relation to their vision, such as a particular resource eliciting undesirable affective responses from students. For example, Mary shared: "If they've [students] tried all the different [curricular resource] lessons, and they're not making progress with any of them, they get frustrated." We added this to our list of vision codes. At the end of this iterative round, we identified the following six codes for vision: (1) Vision about effective instructional approaches for implementing resources to develop students' mathematical understanding, (2) Vision related to creating equitable learning opportunities—scaffolding for individual students depending on their needs, (3) Vision related to creating a coherent curricular experience—strategies for connecting mathematical ideas, (4) Vision related to using assessment to inform instruction and affect student learning, (5) Vision related to reconciling curricular mandates with their own vision, and (6) Vision related to students' affective responses. We recoded the data using these six codes, along with instances of teachers' curricular trust and distrust for each code.

As we reviewed the data, the first two vision codes emerged most frequently (i.e., effective instructional approaches and equitable learning opportunities). This finding guided our second coding cycle, in which we further unpacked the two visions into subcodes to identify the specific types of vision that teachers described in relation to their available curricular resources. We first organized the data into an Excel spreadsheet by vision and then coded inductively to determine the components of each vision code. For example, we examined the specific approaches teachers discussed for creating equitable learning opportunities and how they expressed trust or distrust in various curricular resources. After this inductive coding for each vision, the researchers met to refine the codes and finalize the list of vision subcodes.

Findings

All five teachers described how they selected and used mathematics curricular resources to support their vision of effective instructional strategies and equitable learning opportunities. In this section, we detail the teachers' responses to these visions, highlighting the often-complex nature of their curricular decisions.

Curricular Use: Vision and Trust Related to Effective Instructional Approaches

All five teachers described instructional approaches aligned with their mathematics curricular vision and supported by available curricular resources. Jamie, Mary, and Sarah noted that giving students time for individualized or independent learning allowed teachers to work with struggling learners. They agreed that IXL is a trusted curricular resource for its differentiated approach. Jamie shared, "It's [IXL] also student-paced, individualized, so they're not waiting on their classmates to do a problem or waiting on their classmates to go ahead." Mary and Jamie compared the independent options provided by IXL and DreamBox; both teachers appreciated DreamBox's rigor, as it "does try to create some independence," but agreed that this rigor also

makes it more challenging for students to work individually (i.e., they often reach out to the teacher for help). In contrast, Mary stated that "It's [IXL] not as rigorous as, say DreamBox, and so my students are more successful at doing that [IXL] independently." She added that IXL allows teachers more control over what "students need to work on," whereas "they [students] get a lot of choice with DreamBox. I wish it gave us a little more control." Sarah agreed with the other teachers about the rigor of DreamBox and added that it is "interactive and engaging." She also mentioned the support provided by individual practice resources in enVision's instructional strategy repertoire.

Closely related to independent learning, Kasie and Sarah both cited curricular resources that supported their vision of students' need for "extra practice": enVision, DreamBox, IXL, Study Island, and XtraMath. Kasie expressed appreciation for Study Island:

> It's just a website that makes worksheets for all the subjects, and that's more for practice or small groups. Sometimes, we have our 30 minutes that we're doing Study Island now. During the year, I was in charge of coming up with the curriculum that they would work with our intervention aides, and a lot of the work came from that [Study Island] website, for extra practice.

Kasie and Sarah also mentioned spiraling across the curriculum as an instructional approach within their curricular visions. Kasie shared mixed feelings about the trustworthiness of the spiraling provided by enVision, saying:

> I do like how they [enVision] do kind of spiral and add in some of that stuff that we may have already covered. But when they don't, or we haven't covered it yet, I do adapt it and take those questions away.… or if I feel like it's not something that I really need to concentrate on, or if the kids have already done really well with it, sometimes I'll adapt them and take them off so they don't have to go over that stuff and we can spend more time on the content we're currently working on.

She added that she often uses other curricular resources for spiraling, "We do add in spiraling with IXL or DreamBox, or all the other materials that we have. We do add in that spiraling, where they can come back to it again and again." Like Kasie, Sarah also mentioned using IXL to review skills from the day before.

Audrey, Kasie, and Sarah all mentioned incorporating engaging, enjoyable, contextually relevant, and/or project-based activities as part of their curricular vision. They relied on TPT and other teacher-created activities as their primary curricular resources to support this vision. Audrey and Sarah both described conducting hands-on, project-based activities on Fridays, when the math block is uninterrupted. Sarah shared:

> So, situating those math problems in a familiar context was really fun. And, the activity that we're doing on Friday, I've called it Graph in a Bag [designed by the teacher]. So, I'm just gonna put random things in a brown bag, and the tools to make a graph, and some of those are gonna be plant-related, because we've been doing a big unit on pollinators and pollination and plants. So, just getting familiar subject matter so that the math is the challenging part and not understanding the context of the problem.

Audrey described using TPT activities with multiple mathematical components and engaging contexts, such as Oreos and baseball, for her students. She expressed her enjoyment of teaching "the fun stuff," saying, "I love teaching it. That's my favorite thing to teach, and I think my students know it's my favorite because I get excited about it." Kasie trusts TPT activities as "a

way to see what students have learned and how they can apply it in different ways other than just on the workbook pages or on some type of paper-pencil assessment. So, it's just a different modality for practicing the skill."

Audrey and Kasie also expressed trust in several curricular resources for collaborative learning opportunities (i.e., Study Island, Super Teacher Worksheets, enVision), including opportunities for engagement with the whole class, small groups, and partners. Audrey mentioned opportunities for "practice with partners" in both enVision and Super Teacher Worksheets. She described facilitating whole-class discussions and sharing mathematical authority using enVision:

> So, the easiest thing for me to do is, like, let's pull out our iPads. Let's answer these questions together as a whole class, and if a question arises, you raise your hand, and we can talk it out. And, typically, I have another student answer the question. So, if someone's asking about, like, if we are doing clocks, that was a recent question, with the hands. I had one of my other students volunteer to respond to that question to help them answer it. So, that way, it's not just coming from me all the time.

She also described several challenges associated with helping students appreciate the importance of "working with each other, I'm trying to explain to them that to be successful humans, you have to be able to work with someone, no matter where they are; you have to meet that other person."

Audrey, Kasie, and Sarah expressed trust in the "Visual Learning" videos included with enVision, highlighting several features. Sarah noted the videos' "step-by-step interactive way of how to do the process," adding that "it's interactive, so students drag the symbols where they go." Audrey shared that she begins each lesson with the videos, as they "show exactly what the content is supposed to look like for graphing, collecting data, and finding resources to collect data" (this example was in the context of describing a particular lesson). Kasie also trusted the enVision videos:

> I like the videos that come along with it [enVision]. It helps to give a visual learning experience to our students, and each lesson has two different videos that each take a different approach, so I like that they teach it in different ways as well.

Like Kasie, Audrey trusted curricular resources that illustrated multiple strategies; in her case, she highlighted XtraMath, a program that promotes various strategies for fact fluency. Jamie also trusted XtraMath to develop fact fluency; in particular, she valued its progressive approach to mastering basic facts (e.g., "we're gonna work on the twos today"). Both Audrey and Mary advocated for students using what they called "paper-pencil" at times. Mary commented that "enVision does have everything digitally," but appreciated that students could also complete the "enVision pages" with "paper-pencil." Audrey agreed, saying:

> Drawing with your finger [on your iPad] is not the same as actually paper-pencil. So, especially when they're adding and subtracting and lining those things up on paper, it's easy to get sloppy. So, I have really been diligent about this is what we're doing, and we're gonna put the iPad away and have time to be here and use our blocks and use our counters and use everything that we actually have in front of us.

Mary also mentioned using manipulatives such as fraction tiles, clocks, and coins.

Four of the five teachers expressed trust not only in using a single curricular resource but also in optimizing the potential of their full set of resources, including their primary curriculum

(enVision), their mandated supplementary resource (DreamBox), and other non-mandated curricular resources available to them (e.g., FlashToPass, IXL, Study Island, Super Teacher Worksheets, TPT, XtraMath, and resources they designed themselves). Kasie shared the flexibility that access to multiple resources provides for pedagogical approaches:

> I have them get on IXL or something independent, so I can find something that is going to at least make a little more sense, or find a YouTube video, or find something that might explain it in another way that I'm not thinking of at that time. Then, also find another material that I can bring in and incorporate the next day. Again, if I have to change it on the fly, then sometimes I'll have them working independently on an app or something to give me a moment to figure it out, but usually, it's more about changing it in the coming days.

Similarly, Audrey appreciated having multiple curricular options for students: "I would say, I want seven minutes of this standard on IXL, and afterwards, you can choose. You could either get on DreamBox, or you could do FlashToPass, or you could do another IXL that you didn't get mastery."

Finally, three teachers (Mary, Kasie, and Sarah) expressed trust in the pedagogical sequence embedded within enVision lessons, highlighting the routine as a curricular strength. Kasie shared:

> We usually follow the same kind of pattern. In the book [enVision], it starts with problem solving [Solve and Share], and then we watch a video, and then we do some group problems together, then they do independent problems, and we check them. So, kind of following that same pattern. The kids know what to expect….So, my students have made that connection with math, which helps them with their routine, and they know what's coming throughout our math block.

Sarah concurred and reported using this routine, saying:

> My direct instruction and guided practice, and the online materials, there's a video called Visual Learning that does a great step-by-step interactive way of how to do the process for whatever the skill is today. So, I use that to start each lesson, and then we go to some of the workbook pages and use that as our guided practice.

Both Kasie and Sarah trusted enVision as their primary curricular routine and supplemented it with other resources as necessary. Kasie shared:

> I will start with enVision first, since that's the program that our corporation has purchased, and I'll look through all of the materials that it has on the standard. And then, if I feel like it's not enough, or it's starting too far ahead of where my students are, that's when I'll go and find other materials to start with, or find other materials to work in, but I usually start with enVision every time I start my planning.

So, in addition to the specific instructional approaches the teachers reported trusting (e.g., independent learning, spiraling, extra practice, collaborative learning, project-based activities), they also highlighted their trust in the curricular resources and the pedagogical sequences available within them.

Curricular Use: Vision and Trust Related to Creating Equitable Learning Opportunities

The teachers considered how to use mandated curricular resources and when to supplement them with other resources, depending on how effectively they could create equitable learning opportunities for their students. The teachers spoke about how curricular resources allowed them

to differentiate in several ways, how the functionality of resources enabled or did not enable the creation of equitable learning opportunities, when resources would afford them the opportunity to use and validate multiple strategies, and whether students had access to resources.

The teachers most frequently reported that their trust (or distrust) in mandated or supplemental resources hinged on whether those resources offered opportunities to differentiate instruction to meet individual students' needs. The teachers discussed differentiation in terms of comprehension, pace, and student engagement. Regarding comprehension, all five teachers indicated that digital resources, specifically IXL, enabled them to adjust content for students at different levels of mathematical understanding. For example, Mary shared,

> I use it [IXL] more for differentiation. I have a student who is working at least a grade level above in math, so on his IXL, I can set it to the fourth-grade level, and he can practice the same standards that I'm teaching, but at the fourth-grade level, so it's a little more rigorous and more set to his ability level.

In this example, Mary shared that IXL was useful for differentiating content so she could support students who were ahead of the rest of the class in terms of comprehension; however, IXL is also helpful for supporting students who are working below grade level.

The teachers also discussed differentiation in terms of pace. They indicated that they selected certain supplemental resources to meet the needs of students whose pace was different (faster or slower) than the rest of the class. Jamie trusted IXL because it aligned with her vision that students should work at their own pace: “It [IXL] is also student-paced, you know, totally individualized, so they're not waiting on their classmates to do a problem or waiting on their classmates to go ahead or things like that.”

Finally, the teachers discussed differentiation in terms of student engagement. As such, the teachers envisioned that engagement with the content for individual students might look different. Kasie shared

> So, I've been trying to find games or other activities that make it more engaging, so that they're paying attention to the lessons. I have a lot of students who have ADHD or just struggle, in general, are lower in math, and have a harder time engaging in a lesson when they get frustrated. Finding a fun way to incorporate the math has been something I've been trying to concentrate on this year.

Kasie expressed trust in supplemental resources outside the core curriculum (i.e., enVision), such as games sourced from TPT, to accommodate students with special needs and to provide “fun” activities for students who are typically less engaged.

Some of the teachers’ visions for creating equitable learning opportunities for their students extended to selecting and implementing supplemental materials or adapting the core curriculum for groups of students to better accommodate varying levels of comprehension, pace, and engagement. For example, some teachers described intentionally selecting a limited number of problems for whole-class discussion while allowing students to work independently on others, based on the anticipated rigor or difficulty for different groups. The decision to select fewer problems or to group students was based on how teachers envisioned the rigor of particular mathematics content. For example, Audrey shared

> Sometimes I feel that I neglect my high ability students because I actually have the lowest in our grade level and the highest in the exact same room, and I focus a lot of my attention on my lower-achieving students because I feel that's more of my job. I have a lot more energy

> going into them, and so, when I get to do XtraMath with these students, it's a time for them to shine and to feel successful.

In this example, Audrey grouped her students into 'higher' and 'lower' achievers and provided them with different resources for extra practice, indicating the breadth of her work as she plans and uses curricular resources for different groups of students. As we saw in these examples, teachers often trusted online resources, especially IXL, to achieve their vision for differentiation.

Beyond these strategies for supporting students through practice, teachers emphasized the importance of validating diverse strategies and representations across materials. Teachers described intentionally using multiple resources to help students recognize connections across tasks, which they believed increased students' confidence and engagement. Audrey shared, "we have manipulative bags in the back of the classroom, and we just grab them for every math lesson, just in case, because we never know what students will need." Sarah expressed her trust in enVision because it is research-based and supports the use of multiple representations:

> They're [enVision] not something that somebody created on the internet. The strategies that are included in a research textbook have been researched and shown to support student learning, support learning modalities of different students, or different representations of the ways that they can learn… Since I'm not a math research person, I should trust the research that has been done for me.

This was one of the few instances in which the teachers expressed trust in mandated resources in the context of differentiation and achieving equity. This example and Mary's quote above about her distrust of enVision show how two teachers trusted or distrusted the same resource depending on whether it aligned with their vision. From Mary's perspective, enVision did not offer students opportunities to practice at their own pace, whereas Sarah valued it for offering opportunities to use multiple representations.

Overall, deciding which supplemental resources to use and varying how they were used helped teachers scaffold instruction for their students. The most important aspects for these teachers were opportunities for students to practice at their own pace and to work on content appropriate for their comprehension levels. In all cases, teachers strived to support their students (whether by finding games or using online resources), indicating their care for students and highlighting the complex work inherent in making curricular decisions.

Conclusion and Discussion

Our findings revealed the intellectual effort elementary teachers put into decisions about curricular use, supported the notion that curricular vision and trust are mutually reinforcing, and offered insights for future investigation into how curriculum developers and school administrators can support teachers' work in the mathematics classroom. All five teachers made purposeful decisions about which available curricular resources to use and when and how to use them, in ways they believed best supported their students. In relation to the teachers' vision of effective instructional approaches, they preferred curricula that enabled them to provide time for individualized and independent learning, extra practice and review, and multimodal experiences. In relation to how the teachers envisioned equitable learning opportunities, they were most interested in the ability to differentiate instruction to meet individual students' learning needs, paying special attention to comprehension, pace, and student engagement. In line with both the teachers' vision of effective instructional approaches and equitable learning opportunities, the teachers used curricular resources that offered engaging, enjoyable, and contextually relevant

learning experiences for their students, frequently sourcing TPT to do so because it is a "go-to" resource for them. Further investigation into the impact of introducing teachers to alternative curricular resources that satisfy their visions of engaging and enjoyable learning experiences and align with differentiation practices advocated by the National Council of Teachers of Mathematics (2014), such as those that "promote mathematical reasoning and problem solving and allow multiple entry points and solution strategies" (p. 10), is a logical next step toward ensuring mathematical success for all.

GENERALIZATION IN GHANAIAN MATHEMATICS TEXTBOOKS: A COMPARATIVE ANALYSIS USING ELLIS'S TAXONOMY

Samuel Kenney
University of Delaware
Smkenney@udel.edu

Charles Hohensee
University of Delaware
hohensee@udel.edu

This paper compared two Ghanaian government-approved grade seven mathematics textbook series, Best Brain and the Mathematics Association of Ghana, to identify how they support students to generalize in the Patterns and Relations strand. Using qualitative content analysis, the selected number of tasks were coded with codes informed by Ellis's (2007) Generalization Taxonomy: relating, searching, and extending. It also examines whether tasks invite direct-measure reasoning or emergent-ratio reasoning. In a closer analysis of 49 tasks, extending is the most common generalizing action in both series; however, emergent-ratio reasoning opportunities were rare, present in only seven of 49 tasks (14%). These results suggest that teachers would be advised to supplement the textbook tasks to help students move beyond direct-measure reasoning and engage in deeper forms of generalization.

Keywords: Algebra and Algebraic Thinking, Curriculum

Problem Statement

In a JoyNews report aired on December 1, 2025, the West African Examination Council's (WAEC) Head of Public Affairs, Mr. John Kapi, drew on the 2025 Chief Examiners' findings of West African Senior School Certificate Examination (WASSCE; a mandatory standard test written by all final year Senior High School [SHS] students before progressing to tertiary institutions) and highlighted a persistent concern. He noted that many Ghanaian SHS students struggled with application-focused items, especially tasks framed as "global mathematics-related problems" (JoyNews, 2025). That is, Ghanaian SHS students often have not been able to apply mathematical concepts learned to broader, more abstract, or real-world contexts. That concern means that, for many, generalization of this knowledge is a challenge. Several factors may account for this challenge, including the curriculum (Boaler, 1998), teachers' knowledge and curriculum enactment philosophies (Lambdin & Prestoewsn, 1995; Stickles, 2011), students' role during instruction (Huntley et al., 2000; Remillard et al, 2020), and textbooks (Stein et al, 2007). Research suggests that textbooks, in particular, are a dominant force in shaping the teaching and learning of mathematics globally (Stein et al., 2007). For example, Sugiarni et al. (2024) state that textbooks directly affect how teachers choose to plan and teach, how students gain access to mathematical content, and how mathematical concepts are communicated.

Mason (1996) has described generalization, which is the ability to apply skills learned in a particular context to new, different, or broader scenarios, as at the heart of mathematics. An aspect of mathematics considered foundational for mathematical competency and logical reasoning, and where generalization is central, is algebra (Kaput et al., 2017). The development of patterns and relations is an essential strand underlying algebraic thinking (Blanton & Kaput, 2011), and the generalization of patterns and relations serves as a powerful mathematical tool that allow students to extend examples to more general rules or formulas. Earlier studies have highlighted that students develop the fundamental competencies for algebraic thinking, functional thinking, and quantitative modelling when they work meaningfully with patterns (Blanton, 2008; Kaput, 2008). Yet the extent to which students' textbooks focus on

generalization instead of on procedural manipulation or rote memorization may vary. For example, Ayber and Tanisli (2017) found several gaps in textbooks that attempt to support algebraic thinking through patterns and relations.

Ellis (2007) contends that the kinds of reasoning that are promoted during instruction have a significant impact on students' capacity for generalization. These ideas lead to practical questions for Ghanaian teachers, such as what types of reasoning do our textbooks promote, and do they create sufficient opportunities to meet the national goal of improving problem solving, reasoning, and relational thinking in the new curriculum (Ministry of Education, 2020)? In Ghana, textbooks are the primary curricular material that is readily available and accessible to teachers and students. As a result, textbooks are typically central in teachers' lesson plans and lesson delivery, yet limited research has been conducted on how these textbooks engage algebra students to generalize through patterns and relations. The gap in the literature raises concerns about whether the textbooks available to these teachers and students are adequately preparing SHS students for higher-level algebraic thinking.

Without clear empirical evidence of how algebra textbooks address generalization of patterns and relations, it might be difficult for Ghanaian teachers, curriculum developers, and even policymakers to identify strengths and address weaknesses. This study sought to examine whether Ghanaian junior high school (JHS) textbooks support generalization. To do this, we selected two widely used textbooks: the *Best Brain* (BB; 2021) and the *Mathematics Association of Ghana* (MAG; 2020) textbook series. The BB *series*, though produced by a private institution, is officially approved by the National Council for Curriculum and Assessment (NaCCA), ensuring alignment with national curriculum standards. The MAG *series*, on the other hand, is developed under the guidance of the MoE and distributed nationwide across all Ghanaian JHS. This positions these textbook series to be highly influential in shaping classroom practice. The study reported here specifically analyzed how patterns and relations were presented in these textbooks for grade seven pupils. Examining these two contrasting curricula provided a comprehensive view of how both privately and publicly guided textbooks support students' development of algebraic generalization.

Analytical Framework

Ellis's (2007) Generalization Taxonomy describes the different types of generalizations students develop when reasoning algebraically. This involves the ability to "identify commonalities across cases, extending one's reasoning beyond the range in which it originated, or deriving broader results about new relationships from particular cases" (p. 444). Ellis argued that when students can engage in any of these activities, their reasoning is not limited to one particular problem or situation but extends their ideas to a wider range of phenomena, which ultimately leads to generalization. Additionally, Ellis argues that representations are a key to helping students "create meaningful generalizations" (p. 442).

The framework has three levels: *relating, searching, and extending.* Relating involves forming an association between two or more problems, situations, ideas, or mathematical objects, whereas searching includes engaging in a repeated mathematical action, such as locating a pattern, in order to identify an element of similarity. Finally, the act of extending involves expanding a pattern, relationship, or rule into a more general structure. To measure the extent of generalization, Ellis (2007) suggested two types of quantitative reasoning: direct-measures (DM) reasoning and emergent-ratio (ER) reasoning. Direct-measures reasoning is often procedural or involves recursive strategies, which include counting or computing and completing a table.

Emergent-ratio reasoning, on the other hand, involves reasoning or coordinating two quantities to form a third and is believed to support deeper generalization.

The study, therefore, was guided by the following research questions:

1. What types of mathematical representations are used in the MAG and BB textbook series to assist Ghanaian students' understanding of patterns and relations?
2. How do the MAG and BB textbook series support or not support students' development of generalization, when analyzed through direct-measure and emergent-ratio reasoning across Ellis's dimensions of relating, searching, and extending?

Methods

The data for this study consisted of all tasks within the *grade seven* Patterns and Relations strand from the two Ghanaian government-approved textbook series described earlier. A task was defined as any numbered prompt, with or without distinct subparts (a, b, c, etc.), requiring a mathematical response, including both worked examples with procedures shown and unsolved exercises. The BB *series* contained 69 tasks, and the MAG *series* contained 19 tasks, yielding a total data corpus of 88 tasks across both textbooks for that strand.

Sampling Procedure

For Research Question 1, a complete census approach was used to select all 88 tasks, which were coded for the types of representations used. This approach was adopted to ensure a comprehensive report of all the representations used in both textbook series and how frequently each representation is used in each textbook. For Research Question 2, a stratified systematic sampling technique was used to select 30 tasks from the BB *series* to help maintain a manageable yet robust corpus for in-depth analysis. However, the census approach was used again to select all 19 MAG series tasks to enable meaningful qualitative comparison.

In selecting the 30 BB tasks, tasks were first categorized into five conceptual sections (stratas) mirroring the curricular progression observed in both textbooks: (a) establishing relations, (b) developing patterns, (c) describing rules using mathematical language, (d) reasoning about patterns and far terms with algebraic rules, and (e) graphing and explaining relationships. Within each section, six tasks were selected systematically to capture the progression from early to late tasks within that conceptual phase. Selection followed a fixed protocol: the first task, the last task, and four evenly spaced tasks were selected. If a section contained six or fewer tasks, all tasks were included. This procedure ensured representation across all conceptual phases and difficulty levels, providing a balanced basis for comparing generalization support between the two series.

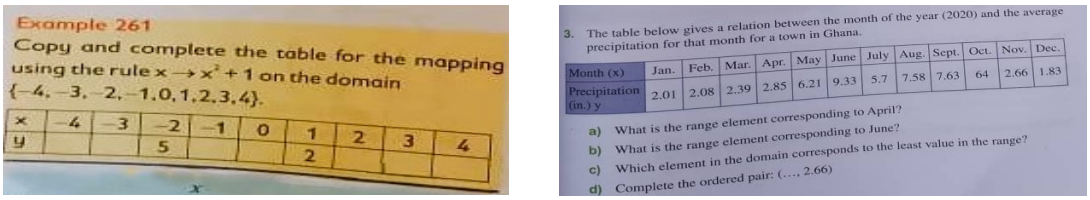
Data Analysis

We analyzed task prompts for opportunities for students to engage in different generalization processes and quantitative reasoning. Tasks that asked students to compare or connect across contexts and to identify similarities were coded for relating. For searching, tasks were coded for prompts that asked students to find the pattern, identify the rule, and verify if the rule holds for all rows. Extending was coded for tasks that asked students to use a pattern to find far-terms or justify that a rule works in general. To ensure reliability of the coding process, 20% of the total dataset was independently coded by a fellow Ph.D. student with expertise in mathematics education using Ellis' (2007) framework. This dual-coding process served as an external audit of the various categories that emerged. It also provided an opportunity to compare task structure, the reasoning demands, and the generalization opportunities provided or not provided by the textbooks. The comparison of codes yielded an inter-coder agreement of 82%, indicating a high

level of consistency in how the framework was applied. Areas of disagreement occurred mainly where tasks blended direct-measure and emergent-ratio reasoning. A resolution meeting ensured that the final codes reflected a shared and rigorous understanding of Ellis' (2007) framework. This collaborative approach strengthens the credibility of the findings and supports the trustworthiness of the interpretations that follow.

Findings

Research Question 1: What types of mathematical representations are used in the MAG and BB textbook series to assist Ghanaian students' understanding of patterns and relations?

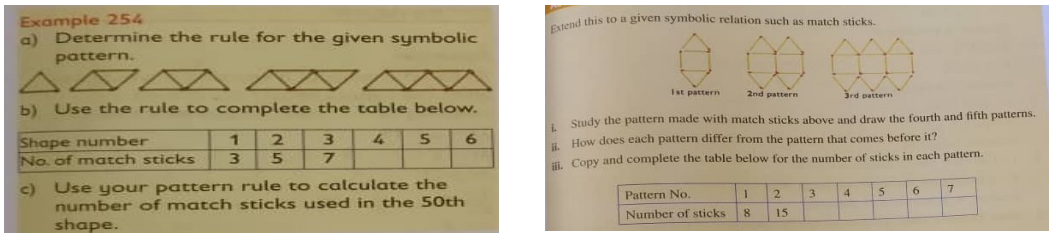


Frequency counts and percentages were used to summarize how often each representation appeared within each series. The six representation types identified in both textbook series were:

- *Words/text:* tasks framed mainly in narrative or verbal form (not just brief instructions).
- *Tables:* Any input-output tables, domain-range tables, or x-y tables
- *Algebraic expressions:* Formulas like $y = 2x + 1$, mappings like $x \rightarrow 3x - 2$
- *Pictures:* Matchstick patterns, growing shapes, diagrams
- *Arrow diagrams:* Arrow mapping structures connecting sets/values.
- *Graphs:* Coordinate axes or graphs presented in the task.

Table 1: Representations Found Across All Tasks

Representation	*BB* (69 tasks)	*MAG* (19 tasks)	Total Codes
Tables	28 (41%)	7 (37%)	35 (40%)
Algebraic	22 (32%)	8 (42%)	30 (34%)
Pictures	15 (22%)	3 (16%)	18 (20%)
Words/Text	12 (17%)	4 (21%)	16 (18%)
Graphs	6 (9%)	2 (11%)	8 (9%)
Arrow Diagrams	4 (6%)	1 (5%)	5 (6%)
Total Codes	87	25	112
Average per task	1.3	1.3	1.3



The output from Table 1 indicated that both textbook series use all six types of representations, but tables showed up most often, about 40% of tasks in both books. They were typically input-output tables showing how one quantity relates to another, like "pattern number vs. number of matchsticks" or "workers vs. lunch cost." In practice, this means students using these textbooks are frequently positioned to make sense of patterns and relations through structured input–output pairs. Algebraic expressions came second, especially in MAG, where they appeared in 42% of tasks compared to BB's 32%. However, MAG treated the algebraic rule as something students use directly to produce values, whereas BB used it as a part of a broader sequence that begins with a pattern or mapping structure, and later students are tasked to graph it. Words/text tasks showed up in 17% BB tasks and 21% in MAG tasks. These were mostly tasks like "write a pattern … and use it to calculate …," "explain the relationship," or "give real-life examples of one-to-many relations." However, a majority of the texts were also used to play a key instructional role in guiding students, yet were not coded as a word/text task. Examples of tables and algebraic tasks are presented in Figure 1 for both textbook series.

BB series ***MAG series***

Figure 1: Example of Tables, Algebra, and Texts Used for Instructions in Both Series

Pictures appeared in 22% of BB tasks but only 16% of MAG tasks. The more important difference is not just about frequency or percentage, but how the pictures are used. For example, the BB series used the matchstick pattern task, which asks students to (a) determine the rule from the symbolic pattern, (b) use the rule to complete a table, and (c) use the rule to calculate the 50th shape. This is a strong example of representational coordination: picture → table → rule → far-term reasoning. Even though a graph is not shown here, the task still uses multiple forms to guide students from visual growth to symbolic generalization. The MAG series also uses a matchstick pattern with a table, but the prompts leaned more toward continuing the pattern, drawing the next cases, and completing the table. The structure supports extension, but the coordination across representations is typically lighter and often stays close to "next steps" rather than pushing strongly toward far-term rule use. Examples of how pictures are used in both textbooks are presented in Figure 2.

BB* series** ***MAG series

Figure 2: Example of Tasks that Use Pictures in Both Textbook Series

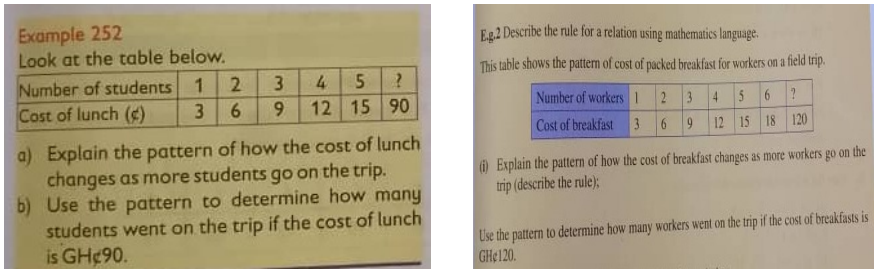
Graphs appeared in only 9% of BB tasks and 11% of MAG tasks, indicating that students do not frequently experience tasks presented in graphs. However, most tasks required students to produce graphs rather than the graphs being used to frame the task. Arrow diagrams occurred in only 5–6% of tasks in both series. Irrespective of its frequency, the tasks showed a clear difference in purpose. For example, in the BB series, they are used mostly for numeric mappings, leading to the formation of algebraic rules. The MAG series had one numeric mapping task, and the remaining used relations in a more contextual/categorical way (e.g., pairing students with towns or matching elements in sets). Even when the language uses the term "relation," the work often reads as organizing or naming pairings rather than as building an explicit function rule. Every task averaged about 1.3 representations, meaning most tasks combine more than one form of representation.

Both textbooks gave students some level of exposure to multiple ways of thinking about patterns and relations. Tables provided concrete structure, algebra gave symbolic power, and pictures offered visual intuition. However, the heavy reliance on tables (40%) means students spend most time working with fixed input-output pairs rather than exploring dynamic relationships. BB's strength was translation and coordination, that is, students see the same pattern as a picture, table, formula, and graph. MAG's strength was algebraic fluency and table-based reasoning, that is, students more often practiced applying rules and completing structured tables efficiently.

Research Question 2: How do the MAG and BB textbook series support (or not support) students' development of generalization, when analyzed through direct-measure and emergent-ratio reasoning across Ellis's dimensions of relating, searching, and extending?

Table 2: Generalization Type by Quantitative Reasoning Lens (ER-present vs DM-only)

Generalization Type	Textbook	Sample Size	ER-present	DM-only	% of Sample
Relating	*BB*	6	1	5	20%
	MAG	7	2	5	37%
Searching	*BB*	9	1	8	30%
	MAG	3	0	3	16%
Extending	*BB*	15	2	13	50%
	MAG	9	1	8	47%
Total	*BB*	30	4 (13%)	26 (87%)	100%
	MAG	19	3 (16%)	16 (84%)	100%
Combined	Both	49	7 (14%)	42 (86%)	100%



The output from Table 2 indicated that across both series, extending was the most common generalizing action. In BB, 15 of 30 tasks (50%) were coded as extending, and in MAG, nine of 19 tasks (47%) were extending. This suggested that students' opportunities to generalize in both textbooks most often take the form of continuing patterns, completing additional entries, or producing further cases beyond what is given. Many of these tasks allowed students to be successful by continuing a sequence or filling the next few values in a table, often by noticing a term-to-term change (e.g., "add three each time," "multiply by two each time"). What distinguishes the stronger extending opportunities is when a task pushes students beyond nearby continuation and toward using a generalized rule for far cases (e.g., a 50th term, unknown inputs, or a symbolic expression that applies to all terms). BB's extending set included more of these "rule-based" extensions in structure, especially when students were tasked to use expressions such as $2n + 1$ or $3x + 2$ to reach distant terms or solve for unknown inputs. MAG's extending tasks, by contrast, more often kept extension close to the given data (extend by one or two steps; complete missing entries), so most of the generalization tends to remain local.

Beyond that shared emphasis, the two series differed in how they allocated attention across the other generalization types. MAG devoted a larger share of tasks to relating (seven of 19 tasks, 37%) than BB (six of 30 tasks, 20%). In practical terms, relating in the MAG textbook series often appeared in contextual pairings where students match or connect items in the domain and range (e.g., category-to-category relations such as countries to national teams). These tasks support the idea of "relation," but many still keep the work inside one representation, rather than pushing students to translate across forms or compare across situations. In BB, on the other hand,

relating showed up when students are asked to coordinate multiple depictions of the same relationship, for example, by linking a pattern image, a table, and an algebraic rule, or by connecting a mapping diagram to a table and a graph. In that sense, when BB did include relating, it more often involved cross-representation coordination.

In addition, BB devoted a larger share of tasks to searching (nine of 30 tasks, 30%) than (three of 19 tasks, 16%). Searching tasks tested whether the same relationship holds across several pairs, rather than simply continuing the next step. In BB, many table and mapping tasks explicitly steer students toward identifying a consistent rule ("find the rule," "write the rule," "use the rule to complete the table"). Doing that required checking the relationship across multiple pairs of representations to identify what stays the same. In MAG, an example of searching tasks was for students to observe a pattern and "find out which one satisfies the relation $x \rightarrow 3x + 1$" (p. 92).

When viewed through the quantitative reasoning lens, the strongest pattern in Table 2 was the dominance of DM-only reasoning in both series. In BB, 26 of 30 tasks (87%) were DM-only, and only four tasks (13%) were ER-present. Similarly, MAG included 16 of 19 tasks (84%) coded as DM-only and three tasks (16%) coded as ER-present. Combined across both series, 42 of 49 tasks (86%) were DM-only, while only seven tasks (14%) showed ER-present opportunities. For example, in the BB *series*, "Example 252" asked students to do more than fill in missing values. Students were prompted to explain how the lunch cost changes as the number of students increases and then to determine the number of students when the total cost is GH¢90. That pairing of verbal explanation and solving for an unknown input naturally foregrounds an emergent-ratio reasoning. A closely related structure appeared in MAG's "Eg., 2" task on breakfast costs. There, the cost of breakfast in the table increases at a steady rate, per-worker, and students are asked to describe the rule and determine how many workers correspond to a total cost of GH¢120. In both cases, the tasks positioned students to treat "cost per person" as the governing relationship, making them strong examples of ER-present prompts. Examples of ER tasks for the BB and MAG textbook series are presented in Figure 3.

BB series ***MAG series***

Figure 3: Tasks that Support Emergent-Ratio Reasoning

Discussion

Ghana's new curriculum aims for students to classify, generalize, and reason relationally, but this analysis suggested that the two approved grade seven series, MAG and BB, may still position students to repeat procedures rather than build deeper structures, since most tasks remained DM-only. This aligns with Ayber and Tanisli's (2017) caution that textbooks can underemphasize generalization, and with Stein et al.'s (2007) view of textbooks as strong

mediators between curriculum aims and classroom practice. Both series included many tasks that fit Ellis's (2007) generalizing actions, relating, searching, and extending. However, most opportunities were DM-only, and few were ER-present, suggesting that generalization often became local continuation, table completion, and rule application rather than relational or functional reasoning grounded in emergent quantities (Ellis, 2007). The two books also position algebraic thinking differently. MAG leaned toward contextual relations and matching within tables or diagrams, but it often stopped short of pressing students to state and justify general rules across cases, which matters for algebraic thinking (Blanton & Kaput, 2011; Ellis, 2007). BB more often pushed students to "find the rule," use it for far terms or unknown inputs, and move across representations, which could better mediate functional thinking, yet it still rarely asks students to justify why the rule works or what stays invariant as quantities co-vary, so ER reasoning may remain limited. Taken together, the findings suggested teachers will likely need to extend tasks by pressing for justification, cross-representation connections, and give explicit attention to emergent-ratio relationships, reinforcing the idea that textbooks shape, but do not fully determine, students' opportunities to learn (Stein et al., 2007).

Limitations of the Study

The analysis was limited to the grade seven Patterns and Relations strand and to two Ghanaian government-approved textbook series, BB and MAG. It also uses a full census for representation coding (88 tasks) but a smaller in-depth sample for generalization coding, 30 tasks from BB plus all 19 MAG tasks, so the deeper claims came from that sampled corpus rather than every task in the BB *series*. Future research could look at other strands in BB and MAG and other textbooks.

Recommendation for Classroom Practice

Because DM-only tasks dominate and ER-present prompts were rare, the paper recommends that teachers who want to meet the curriculum's reasoning goals will often need to extend what the textbook tasks ask for. Teachers will have to press students to compare cases, connect tables, diagrams, and graphs, and justify why relationships hold, instead of stopping at completing tables or applying rules. This means the possibility for students to reorganize actions into deeper structures, reason with ratios, and/or articulate general rules relies heavily on teacher mediation.

Conclusion

The findings revealed that although both textbooks included a variety of representations and task structures that introduced students to patterns and relations, the depth of reasoning they elicit differs. The dominance of tables and text in both textbook series suggested that students are often positioned to read, fill, or extend given representations rather than coordinate multiple representations to uncover an invariant relationship. The findings also showed that while generalization was not absent, it is largely framed through direct-measure (DM-only) reasoning. Taken together, the results revealed that the textbooks provided a foundation for generalization but did not fully realize the constructivist and relational aspirations of Ghana's current curriculum reforms.

There is a need in the field for classroom observation tools made for and used by teachers to reflect on and instigate improvement in their own practice. Classroom observation tools were commonly designed to evaluate instructional practices, measure implementation and growth following professional development, and compare teaching across contexts. In this paper we share results from analyzing 13 classroom observation tools for K-12 mathematics classrooms with a focus on the tools' purposes and usability for both researchers and teachers. We found that these tools generally fall into one of two categories: Tools for Teacher Reflection or Tools about Teacher Practices.

Keywords: Assessment, Professional Development, Research Methods, Teacher Educators

Over the past 30 years, many classroom observation tools were developed and used for various reasons. Often these tools are used by teacher educators, instructional coaches, and school leaders to evaluate teaching and provide feedback to improve teaching practices. Observation tools are generally developed by researchers for specific purposes (e.g., assess professional development, measure teachers' implementation of a specific practice, improve specific teaching practices). Although classroom observation tools are widely used to evaluate teaching practices, the extent to which they support teachers' reflective growth is not clear. Observation tools structured primarily for evaluation are unlikely to adequately support teacher reflection; therefore, intentionally designing tools with reflection as a primary purpose might hold more promise for improving practice.

In this paper we report on thirteen classroom observation tools developed for use in K-12 mathematics classrooms with a focus on the tools' purposes and usability for teachers and researchers. One of these observation tools is new (Roth McDuffie et al., 2026) and was designed using the AERA validity standards (2014), with the purpose of assisting middle school mathematics teachers to reflect on their own reasoning about mathematical decisions they encounter in their classroom as they plan, implement, and reflect on their lessons.

Purpose and Framework

Existing classroom observation tools were commonly designed to evaluate instructional practices, measure implementation and growth following professional development, and compare teaching across contexts. While these purposes are important for researchers, they position observation tools primarily as tools of measurement rather than tools for teacher learning. Consequently, these tools might not guide teachers through a reflective process.

Phillips et al. (2023) defines "teacher reflection as the process of teachers critically evaluating their instructional experiences to improve their practices and students' learning" (p. 636). Building on earlier conceptualizations of reflective teaching (Ur, 1999; Mathew et al.,

2017), Phillips et al. (2023) articulates a structured model for teacher reflection that includes three components: (1) collecting quality classroom data, (2) conducting a thoughtful analysis and evaluation of the data, and (3) contextualizing an interpretation of the data to inform teachers' practices. Observation tools intended to support teacher reflection can generate quality data, guide meaningful analysis, and assist teachers in constructing contextualized interpretations. With the definition of and steps for teacher reflection framing our work, we examined existing classroom observation tools and determined their usability to support teacher reflection.

Ur (1999) argues that for teachers to progress professionally, their own reflection on daily classroom events is critical. Mathew et al. (2017) states, "the complexity of teaching requires teachers to question their practices for their own professional development in order to improve and to increase learner performance" (p. 126). In our prior NSF project (Nos. 1561542, 1561554, 1561569, 1561617) we found that the post-interviews we conducted with mathematics teachers after they taught a lesson caused them to reflect on their own practice. Although our intent with the post-interview was to learn more about teachers' reasoning for their decisions, we found that teachers were deliberately reflecting on their teaching.

To better understand how existing observation tools function in practice, we consider three widely used instruments reviewed by Boston et al. (2015) as examples: the *Reform Teaching Observation Protocol* (RTOP) (Sawada et al., 2000), the *Instructional Quality Assessment* (IQA) (Boston & Wolf, 2006), and the *Mathematical Quality of Instruction Tool* (MQI) (Learning Mathematics for Teaching Project, 2011). Researchers developed each of these tools to observe and measure specific teaching practices: RTOP (Sawada et al., 2000) measures teachers' ability to implement reform-oriented instruction; IQA (Boston & Wolf, 2006) measures teachers' implementation of a cognitively challenging task and the discussion around that task; and MQI (Learning Mathematics for Teaching Project, 2011) measures the rigor and depth of the mathematics taught during a lesson. These three observation tools generate data about different practices teachers use in their classrooms, including ratings or scores based on externally defined criteria, but these tools do not structure opportunities for teachers to analyze their own instructional practices. As a result, their utility for supporting teacher reflection is limited.

Together, these tools illustrate a broader pattern: classroom observation tools are typically structured as summative measures intended for evaluation and comparison. With these tools, the observer, who is trained, determines what counts as quality instruction, applies predefined criteria, and assigns and interprets scores. While such information may inform feedback for teachers, the tools themselves do not scaffold teachers' analysis of their own practices, nor do they prompt teachers to interpret classroom events in relation to their instructional goals. As a result, reflection is not structurally supported. Alternatively, observation tools that function formatively—guiding teachers through a systematic evaluation of their instruction rather than merely assigning scores—offer the potential to support reflective practice.

Methods

We conducted a comparative document analysis of 13 classroom observation tools. The sources of our data included the tools' manuals, protocols, rubrics, websites, and publications. We treated the tools themselves as the data and used consistent criteria to categorize the tools based on design features, structure, purpose, use, and requirements.

Using web-based searches, generative AI queries, and journal articles (e.g., Boston et al., 2015), we compiled a list of 20 observation tools commonly used in mathematics classrooms. We used GenAI queries to generate an initial list of tools (e.g., "provide a list of 20 mathematics classroom observation tools," "provide links to a variety of mathematics classroom observation

tools."), and by accessing official sources, we verified every tool's relevance to our search. We complemented our AI search by conducting a literature search of relevant journals to ensure that the GenAI had not neglected important observation tools. Of the initial 20 tools, we eliminated eight. We bounded our analysis to tools used in preK-12 mathematics classrooms, and consequently, we eliminated six tools because they were primarily used in higher education classrooms. The six eliminated tools included: *The Teaching Dimensions Observation Protocol* (Hora & Ferrare, 2010), *Classroom Observation Protocol for Undergraduate STEM* (Smith et al., 2013), *Oregon Teacher Observation Protocol* (Wainwright et al., 2003), *Student Response to Instructional Practices* (DeMonbrun et al., 2017), *Classroom Discourse Observation Protocol* (Kranzfelder et al., 2019), and *Three-Dimensional Learning Observation Protocol* (Bain et al., 2020). We also eliminated *Inside the Classroom Protocol* (Weiss et al., 2003) used across K-12 math and science classrooms, because this tool's purpose is for large scale comparisons across classroom teaching in the United States, rather than focusing on individual classrooms and teachers. Finally, we eliminated *Generalized Observation and Reflection Platform* (Center for Educational Effectiveness, n.d.) because it is not an observation tool; it is a software program designed for observing classrooms that can be programmed for any given observation tool.

In addition, we included a new observation tool, the *Curricular Reasoning - Observation Assessment* (CR-OA) (Roth McDuffie et al., 2026) in our analysis. The CR-OA tool, designed using AERA (2014) validity standards and developed by a team of mathematics education researchers in collaboration with a team of statistics researchers. The CR-OA tool is part of a larger toolkit, aimed to formatively assess and provide feedback on teachers' use of curricular reasoning—"a specific form of pedagogical reasoning that teachers employ while working with curriculum materials to plan, implement and reflect on instruction" (Roth McDuffie & Mather, 2009, p. 303). The toolkit was intentionally designed to support teacher reflection while also generating meaningful, context-specific data that teachers can use to inform their instructional decisions. The purpose of the CR-OA tool is for observers to collect evidence of observable instructional practices that reflect teachers' engagement with the six curricular reasoning aspects (Dingman et al., 2021). We included the CR-OA tool in our analysis because it was purposefully designed for teachers to reflect on their reasoning as they plan and implement mathematics lessons.

Table 1 lists the 13 observation tools that were analyzed for the study. We began analysis by documenting the stated purpose, publication date, use in the field, audience, validity, reliability, whether the results were used formatively or summatively, the types of classrooms they were designed to observe, structure/theory, the type of rating scale (or lack thereof), and how observations were conducted (e.g., videotaped or live). Using the information gathered on each tool, we identified emergent categories based on how the tools were used in the mathematics education field.

Table 1: Classroom Observation Tools Analyzed Listed by Development Date

Observation Tools Analyzed
Curricular Reasoning - Observation Assessment (CR-OA, 2026)
Early Mathematics Classroom—Pre-K through 2nd grade Instrument (EMC-PK2, 2024)
The Teaching for Robust Understanding Observation Guide for Mathematics (TRU, 2016)
Mathematics Classroom Observation Protocol for Practices (MCOP2, 2015-2017)
Practical Observation Rubric To Assess Active Learning (PORTAAL, 2015)
Mathematics Scan (M-Scan, 2013)
The UTeach Observation Protocol (UTOP, 2012-2018)
Instructional Quality Assessment (IQA, 2012)
Mathematical Quality of Instruction (MQI, 2012)
The Framework For Teaching (FFT, 2007)
Math Observation Checklist and Tool: SERP 5×8 Card (SERP 5x8 Tool, 2003)
Reformed Teaching Observation Protocol (RTOP, 2000-2002)
Formerly known as "*The New Teacher Project*" (TNTP, Creation Date Unknown)

We also examined the reported or estimated training time for each tool and grouped the tools into three categories based on length of training. We defined the three categories of training as: (a) *Easy*, requiring <2 hours; (b) *Moderate*, requiring between 2 to 12 hours; and (c) *Difficult*, requiring >12 hours. We determined the time required for training in two ways. First, several observation tools have websites that describe the training, including information on the number of hours or days required to complete the training. For tools that did not have this option, we consulted articles that reported training researchers or participants on a given observation tool, including training time and sessions (e.g., Rainey et al., 2024; Rogers et al., 2020; Kane & Staiger, 2012). We selected the categories based on how the training might impact teachers' daily schedules. Training requiring <2 hours might reasonably be done outside of school hours, or during a teacher's preparation time built into their schedule. Training requiring between two and 12 hours might take 1–2 school days, perhaps requiring support from the teacher's district to coordinate the training. Training requiring more than 12 hours would likely require more than two days and would require significant effort and coordination by both teacher and the school district to be accomplished.

In addition we grouped the tools based on administrative complexity. The three categories were: (a) *Easy*, which included tools with 15 or fewer indicators and a binary rating scale (e.g., observed, not observed); (b) *Moderate*, which included tools with more than 15 indicators and/or a rating scale of three or four choices (e.g., 1–4 point rating scale); and (c) *Difficult*, which included tools with anything outside the scope of the first two categories and added more complexity (e.g., tools that require the rater to rate the observation every five minutes of a lesson).

Finally, we identified whether the tools and training materials were publicly available without requiring special access or permission. This was important as we were interested in determining whether teachers can use these tools to reflect on their teaching practices.

Results

After analyzing the 13 mathematics classroom observation tools for both purpose and usability, we identified those tools that were more ideally situated for teacher use and teacher reflection, as contrasted with other tools that were better suited for researchers, to collect and analyze data to answer research questions. Each tool we analyzed was created for a distinct purpose (e.g., MQI measures the mathematical work in a classroom (Learning Mathematics for Teaching Project, 2011)), and is used by researchers, private organizations, school administrators, coaches, and teachers to varying degrees. We classified the tools according to their usability, which included the training time, administrative complexity, and public availability. Table 2 displays the 13 tools with information about each tool's usability. Typically, the majority of tools tended to require intensive training and were administratively complex; often these qualities are associated with acceptable to strong interrater reliability when using the tool. The most usable observation tools include, in order of their overall usability, SERP 5x8 Tool (Donovan et al., 2013), CR-OA (Roth McDuffie et al., 2026), TRU Observation Tool (Schoenfeld, 2017), and PORTAAL (Eddy et al., 2015).

Table 2: Usability (Training Time, Administrative Complexity, and Public Availability)

Tools	Training Time	Administrative Complexity	Publicly Available
CR-OA	Easy	Easy	Yes
MCOP2	Easy	Difficult	Yes
SERP 5x8 Tool	Easy	Easy	Yes
TRU	Easy	Moderate	Yes
MQI	Moderate	Difficult	No
PORTAAL	Moderate	Moderate	Yes
EMC-PK2	Difficult	Moderate	No
FFT	Difficult	Difficult	No
IQA	Difficult	Difficult	No
M-Scan	Difficult	Difficult	Yes
RTOP	Difficult	Difficult	Yes
TNTP	Difficult	Moderate	Yes
UTOP	Difficult	Difficult	Yes

The 13 observation tools were sorted into three categories based on their purpose, use, and audience, as shown in Figure 1. A tool categorized as *for Teacher Reflection* (a) uses broad categories and indicators, (b) presents results narratively rather than numerically, and (c) positions the teacher as an interpreter of results. Three tools are categorized as *Tools for Teacher Reflection*. The data gathered with these tools is understandable for teachers, and the results of these tools are formative, providing notes and descriptions rather than numerical scores. These tools also had lower training requirements, which may be because the tools were used to give feedback to teachers. These three tools are different in purpose and how they present the results, yet each provides results that can be interpreted directly by the observed teachers and presents results designed to promote reflection for the observed teachers on improving their own practice.

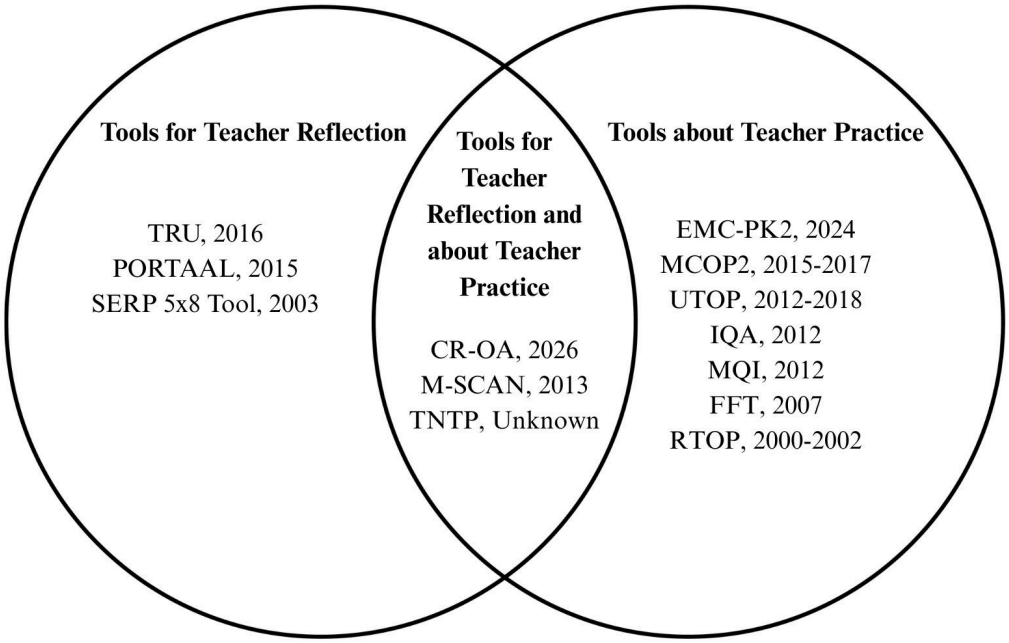

Figure 1: Categories of Observation Tools Based on Purpose, Usability, and Audience

A tool categorized as *about Teacher Practice* (a) includes a rigorous set of criteria to observe, (b) presents results as an evaluation of teacher practices, and (c) offers results that position the observer as the interpreter. Seven tools are categorized as *Tools about Teacher Practices*. These tools fulfill the first two steps of the reflection process as defined by Philips et al. (2023), collecting data and analyzing data, but they do not fulfill the third step, contextualized interpretations. These tools are used mainly by researchers and administrators. They are designed to record what teachers do in the classroom and to determine the quality of instruction, often for the purpose of evaluation or determining the effectiveness of a particular intervention. These tools take a clear normative stance about productive classroom practices, and they measure instruction according to their defined norms, often with complex rubrics and numerical scores. Using the tools and interpreting the results requires moderate to extensive training time. These tools are ideally situated for research as they provide reliable results regarding the quality of teaching. Some tools in this category are also frequently used by district and school administrators and coaches to evaluate teachers given that their results are better suited for reporting and comparison.

We classified three tools as both *Tools for Teacher Reflection* and *Tools about Teacher Practice* because the tools frame their results to be interpreted by the observed teacher and observer for quality instruction. Two tools, the M-Scan and TNTP, require extensive training, and are thus mainly used by researchers and administrators. Due to their extensive training, we viewed these tools as unlikely for teachers to use. In contrast, both the M-Scan and TNTP present results that can be understood by teachers, providing space for teacher reflection, and results can be reliably compared and rigorously analyzed by researchers, providing relevant data about teacher practices in their classrooms. The CR-OA is unique because it frames results to prompt teacher reflection and provides useful data for researchers about teacher's reasoning, while requiring less training time and offering less administrative complexity.

Conclusion

In this paper we aimed to identify classroom observation tools that provide teachers the opportunity to reflect on their teaching practices. We report the results of the analysis of 13 mathematics classroom observation tools that are currently available for teachers, educational leaders, and researchers. We found that the majority of the 13 classroom tools are not intended for teachers to reflect on their practice. Rather the purpose of these tools is to collect data about teachers' practices and often evaluate teacher practices. This suggests that many of these observation tools are developed for researchers and administrators and not for teachers. Further, we found only three of the six tools (CR-OA, SERP 5X8, TRU) that teachers might use to reflect on their practice require less than two hours of training. This creates a barrier to teachers' reflective practice. There is a need in the field to develop and validate tools that provide teachers access to systematically reflect on their teaching practice.

The 13 mathematics classroom observation tools were also limited based on the three components of teacher reflection articulated by Phillips et al. (2023). All of the tools collect quality classroom data. However, the other two components—conduct a thoughtful analysis and evaluation of the data, and contextualize an interpretation of the data—were not accessible for teachers who want to reflect on their practice.

As we have stated, the CR-OA is a new observation tool that was designed and developed using the AERA validity standards (2014). Our purpose in creating the tool was to measure teachers' curricular reasoning; however, we found that as teachers use this tool, they begin to reflect on their own reasoning for their mathematical decisions they made when teaching. This reflective practice made us wonder how many other observation tools are similar. We suggest that as new tools are developed, the field needs to place teachers' needs and reflective practices as an important part of the development of the tools. If the field of mathematics education has the goal to improve mathematics teachers' ability to teach their students, yet the tools we are developing are not helping teachers improve or reflect on their practice, it will be difficult for our tools to be useful to more than the research team who developed it.

Given the importance of graphs in STEM, nuances in how graphs are used across STEM fields is an underexplored area. This study explores the diverse disciplinary expectations for graphical representations across STEM textbooks. We use a framework to analyze graphs based on their coordinate systems, the number and types of reference frames, and visually salient features. We note that while Cartesian graphs representing two continuous quantities are common, there is significant variability in graph use across fields. Our findings have important implications for school mathematics, including the importance of promoting covariational and multivariational reasoning to better prepare students for the specific demands of various STEM disciplines. We conclude with limitations and directions for future research.

Keywords: Undergraduate Education, Integrated STEM, Curriculum, Graphs

Graphs play a central role in STEM disciplines for modeling, analyzing, and communicating phenomena. They function as tools through which STEM professionals reason about and convey complex relationships (e.g., Meira, 1995; Roehrig et al., 2021). Consistent with this, graphical representations are pervasive in STEM textbooks and professional publications (e.g., Lemke, 1998; Paoletti et al., 2020; Roth & Bowen, 1999). Given their widespread use, supporting students in developing robust understandings of graphs is critical for preparing future STEM professionals.

Although graphs are central to STEM, findings from research (e.g., Lai et al., 2016; Ruf et al., 2024) and large-scale assessments (e.g., Nation's Report Card, 2005) suggest that U.S. students have limited opportunities to develop graphing understandings aligned with STEM disciplinary expectations. One potential explanation is that graphs differ within and across STEM fields—varying in how they are constructed, interpreted, and used (e.g., Paoletti et al., 2020). Although these disciplinary expectations likely shape how graphs are used and understood in different fields (Bowen & Roth, 2003), such differences remain insufficiently categorized in STEM education research. The overarching aim of this study is to explore similarities and differences in disciplinary expectations across STEM fields by using an existing framework that accounts for the various aspects of graphical representations. Accordingly, our research question is: *What are the similarities and differences in graphs used across STEM fields?*

In this report, we build on our on-going research by leveraging theoretical constructs that capture nuances in how students may conceive of graphs, coordinate systems (CSs) on which graphs are represented, and the reference frames (RFs) represented via the CSs. We organize these constructs along three dimensions: (a) the type of CSs, (b) the number and types of RFs, and (c) the object(s) students are expected to interpret within the graph space. Figure 1 provides a high-level overview of our framework; we provide more detail in the sections that follow.

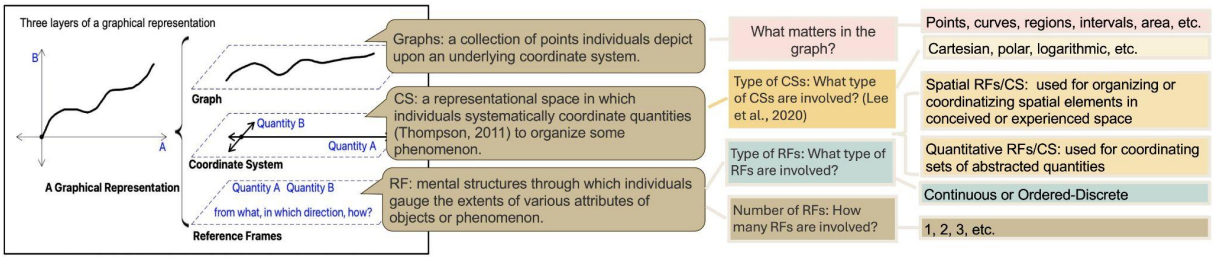

Figure 1: A Framework for Examining Graphs at a Fine-grained Level

Literature and Theory Relevant to Aspects of Graphs Across STEM Fields

In this section, we frame our discussion of literature and theory using six graphs (Figure 2) which are recreations of graphs similar to those found in textbooks across different STEM fields. We recognize that disciplinary knowledge is required to make sense of each graph and its different aspects (e.g., Altindis et al., 2024; Roth et al., 1999; Roth & Bowen, 2003; Zimmerman et al., 2023). Accordingly, we do not attempt to offer a full interpretation of each graph. Instead, we focus on supporting the reader in understanding how our framework (Figure 1) can help us identify similarities and differences across the examples that may inform instruction in undergraduate STEM courses.

Coordinate Systems

A CS is a representational space through which an individual relates quantities to make sense of a phenomenon (Paoletti et al., 2025; Thompson, 2011). Such spaces commonly involve the coordination of two quantities, though they may involve more. For example, Figures 2(a and d) represent CS that coordinate two quantities, while Figure 2f clearly involves more than two.

Across STEM disciplines, multiple forms of *conventional* CS are used. While Cartesian axes like those in Figure 2f are most commonly used in US Curricula (Lee & Guajardo, 2023; Paoletti et al., 2020), graphs using polar (or polar-like) CS (Figure 2a-b) and logarithmic scales (Figure 2d-e) are also used. Such conventions are important because researchers have shown that graphing conventions can influence students' thinking about graphs, often in unintended ways (e.g., students carry rules that apply in one conventional CS to another in which the rules do not apply; Montiel et al., 2008; Moore et al., 2014).

We distinguish between two broad types of coordinate systems: *spatial and quantitative* (Lee, 2017; Lee et al., 2020). A *spatial CS* is one through which an individual organizes elements within conceived or experienced physical space. In contrast, a *quantitative CS* emerges when an individual abstracts quantities from a phenomenon and organizes them within a representational space that differs from the original physical context. Here, the space does not mirror physical layout; rather, it provides a structure for coordinating quantities.

In some mathematical contexts, graphs may not involve clearly identifiable situational quantities (e.g., graphs representing abstract variables x and y), and not all graphs align neatly with either CS described above. Nevertheless, the distinction between spatial and quantitative CSs has proven useful in prior analyses of middle school and STEM textbooks (Lee & Guajardo, 2023; Paoletti et al., 2020), as well as in explaining differences in students' graph construction and interpretation (Knurek, 2025; Paoletti et al., 2025). Taken together, these distinctions offer a productive lens for examining the varied roles CSs play in undergraduate STEM contexts.

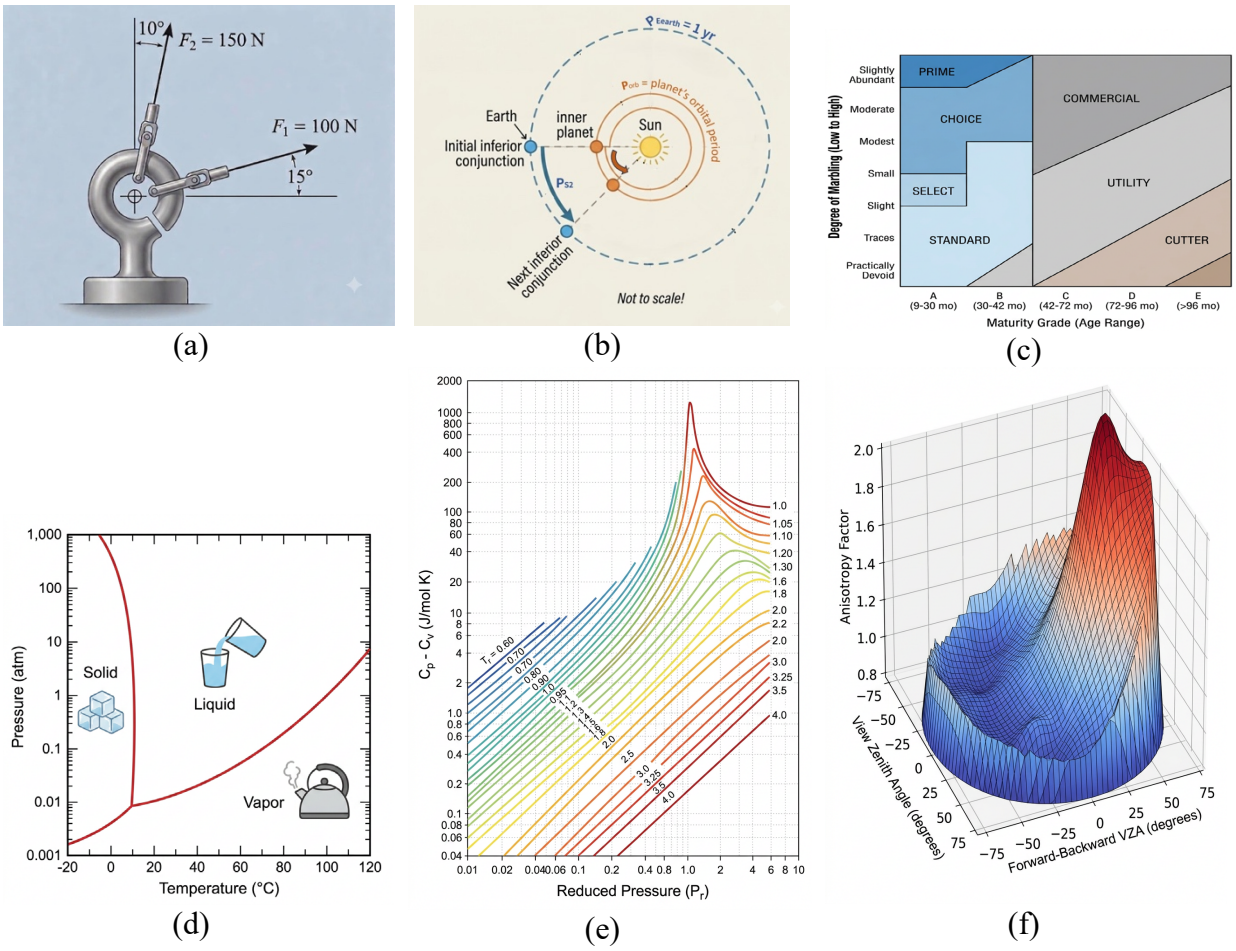

Figure 2: Recreations of Graphs from Six Textbooks: (a) Mechanic Statics (Hibbeler, 2015. p. 23), (b) Astronomy (Bennett, 2011, p. 93), (c) Agriculture (Field & Taylor, 2015, p. 120), (d) Material Science (Callister & Rethwisch, 2013, p. 297), (e) Chemical Engineering (Sinnott, 2005, p. 70), and (f) Environment (Jensen, 2013, p. 373)

Reference Frames

A CS comprises one or more RFs. RFs are mental structures through which an individual coordinates various attributes associated with objects or phenomena (Lee, 2017; Levinson, 2003). The construct of RF has played a central role in research on spatial cognition (e.g., Levinson, 2003; Taylor & Tversky, 1996), children's conceptions of space (e.g., Piaget & Inhelder, 1967; Piaget et al., 1960), and quantitative reasoning (e.g., Joshua et al., 2015; Lee et al., 2019). Across these domains, RFs are understood as cognitive structures that enable individuals to coordinate and compare attributes within a representational space.

Within a CS, RFs can be represented via quantities represented on axes as well as through other objects within the graphical space (i.e., a series of related curves (Figure 2e) or distinct regions within the graph (Figure 2c–2d)). It is common for CSs to represent two RFs. As with CSs, we distinguish between spatial and quantitative RFs, with some graphs including one (or more) spatial and one (or more) quantitative RF represented (Knurek, 2025). When students interpret graphs structured by two RFs, they may be asked to determine the value of one quantity at a specific value of another, or to reason about how two quantities vary together. Interpreting

how two quantities change together entails covariational reasoning (Thompson & Carlson, 2017).

In some contexts, CSs can represent three or more RFs. Interpreting graphs with 3 or more RFs requires coordinating multiple quantities simultaneously, which entails multivariational reasoning (Jones, 2002; Panorkou & Germia, 2023). Research suggests that learners as young as middle and high school can demonstrate such reasoning (Bagossi, 2024; Panorkou & Germia, 2023). Examining the prevalence of such graphs in undergraduate STEM courses can inform the design of curricular materials that better support students' interpretation of such representations.

Beyond considering the number of RFs represented in a graph, our research has identified distinctions in how students interpret graphs as representing continuous versus ordered-discrete RFs (Olshefke-Clark et al., 2024, accepted). In many instructional settings, students are asked to interpret graphs that represent continuously varying quantities (Figure 2e–2f). In other cases, however, graphs represent discrete but ordered regions within a graphical space (Figure 2c–2d). For example, Figure 2c describes both the degree of marbling and an animal's maturity in discrete but ordered chunks (i.e., traces, slight, small, as progressively increasing marbling). Interpreting such graphs entails attending to those regions rather than to continuously varying relationships. In such contexts, curriculum designers may expect students to reason about regions or about specific points within those regions. The extent to which undergraduate STEM curricula emphasize interpretations based on points, lines, or regions remains an open question.

Methods

To address our RQ, we followed a purposive multi-stage sampling process (Babbie, 2020) to identify commonly used textbooks across a variety of STEM fields. First, examining the STEM offerings at a variety of undergraduate institutions (e.g., UD, Texas State, Montclair State), we identified several STEM disciplines that we conjectured may provide novel insights into graph use across STEM (e.g., Agriculture; Chemical Engineering; Mechanic Statics). After identifying several STEM fields of potential interest, we used the Open Syllabus Project (OSP), which has a large-scale database aggregating curricular data from millions of syllabi.

Using OSP, we identified the three most commonly used textbooks in each STEM major, ranked by their frequency in syllabi. We then searched for digital or physical versions of these textbooks available to the research team (e.g., PDFs, versions from university libraries). Through this process, we aimed to select books that were actually used in university STEM instruction. Table 1 provides a summary of the 6 STEM textbooks we report on in this paper. In total, we identified 856 graphs, which we coded via the process described below.

Table 1: Summary of Six Selected Textbooks

STEM Discipline	Textbook Title & Authors	Published Year	Rank	# of graphs
Agriculture	Scientific Farm Animal Production: An Introduction (11th Ed.) by Field and Taylor	2015	2	48
Mechanic Statics	Engineering Mechanics: Statics (14th Ed.) by Hibbeler	2015	3	294
Chemical Engineering	Chemical Engineering Design (4th Ed.) by Sinnott	2005	2	123
Astronomy	The Cosmic Perspective (6th Ed.) by Bennett	2011	1	151

Environment	Remote Sensing of the Environment: Pearson New International Edition: An Earth Resource Perspective (2nd Ed.) by Jensen	2013	1	128
Material Science	Materials Science and Engineering: An Introduction (9th Ed.) by Callister and Rethwisch	2013	1	112

Coding

We coded each graph that represented at least two quantities in each book. We located the graph and identified the number of distinct reference frames (RFs), the types of RFs across two dimensions, the types of conventional coordinate system (CS), and the visually salient features. We describe and use examples selected from each textbook to illustrate our coding strategies.

Number of RFs (2, 3, 4+). To code for the number of RFs, we examined how many pieces of information a student would need to coordinate to potentially make sense of a graph in ways compatible with the authors' intentions. If a graph involved only two quantities and each was represented in RF, we coded it as "2 RFs." For example, Figure 2c represents the relationship between two quantities, maturity and marbling, and they serve as the horizontal axis (maturity) and the vertical axis (marbling) in a two-dimensional CS. If the representation required coordinating an additional RF beyond two axes, we increased the RF count to "3". This included cases such as: a secondary axis (i.e., two different variables are plotted against the same horizontal axis), three-dimensional surface plots (e.g., Figure 2f), graphs linked to a physical situation diagram or vector-direction frame that must be interpreted simultaneously (e.g., a schematic of the celestial sphere), or graphs where the user must coordinate the two axes with an internal family of curves representing a third quantity (e.g., Figure 2e). When the representation stacked multiple layers of coordination (for instance, an embedded physical diagram or multiple axes), we coded it as "4+," indicating four or more frames operating together.

Type of RFs: Dimension 1 (Quantitative, Spatial, Both). We then characterized the type of quantity each RF represented, either spatial, quantitative, or both. If the RF represented a quantity in a space intended to be different from the space in which the quantity should be conceived, we categorized that RF as quantitative (e.g., Figure 2c-f). If the RF was represented in a space analogous to the space in which the quantity is intended to be conceived, we coded the RF as spatial (e.g., Figure 2a-b). When a graph had both spatial and quantitative RFs (for example, motion graphs, vector diagrams with magnitude, or graphs tied closely to a pictured situation), we coded it as Both.

Types of RFs: Dimension 2 (Continuous, One or more Ordered-Discrete). For each RF we identified, we characterized whether this RF was intended to represent a continuous or ordered-discrete RF. If a graph exclusively used continuous or ordered-discrete RFs, we coded the graph as Continuous or Ordered-Discrete. As we coded graphs, we noticed that many graphs represented one (or more) continuous and one (or more) ordered-discrete RFs, leading to the code Mixed. In this report, we group Mixed and Ordered-Discrete into one category called One or More OD. We also identified several graphs in which one quantity was not continuous or ordered discrete (e.g., categorical labels such as names, colors, or types); such graphs were coded in an Other category that we do not present in the current report, as there were few such cases.

Type of conventional coordinate system (Cartesian, Logarithmic, Polar, Mix, other). Next, we classified the coordinate system itself. If the graph used perpendicular axes, we coded it as a Cartesian CS (e.g., Figure 2f). If it used a polar structure (i.e., one angle, one radial

distance), we coded the graph as having a polar CS (e.g., Figure 2b). If both axes were logarithmic, we coded the graph as having a logarithmic CS (e.g., Figure 2e). If multiple coordinate systems were used across the representation, we coded the graph as mixed (e.g., Figure 2d). Anything that did not fit the above descriptions was coded as Other.

Visually salient features. We coded the visual elements designed to stand out, as these elements often signal what the authors expect students to attend to while interpreting the graph; we note that a single graph could be coded with multiple visually salient features. For example, if a graph included discrete plotted points, we coded *Points* as visually salient (e.g., Earth in Figure 2b). If the graph included a connected curve or trend, we coded *Lines in the graph* as visually salient (e.g., the red curves in Figure 2d). We coded *Regions* as visually salient in graphs that shaded or bounded areas (the regions in Figure 2c, d). Similarly, we included codes for *Bars* (e.g., bars in a bar graph), *Vectors* (e.g., Figure 2a), *Lines to axes* (e.g., Figure 2e), and *Physical objects* (e.g., Figure 2d) as visually salient features within a graph. Figure 2d provides an example of a graph in which lines in graphs (the red curves), regions (Ice, Liquid, Vapor), and physical objects (ice cube, pitcher of water, tea kettle) were all coded as visually salient.

Results

In this section, we present the results of our coding. We first describe the number of RFs in each graph. We then characterize the graphs across the two dimensions of RFs and the conventional CSs we observed. We conclude by presenting the visually salient features.

Table 2 presents the number of RFs in each textbook. We highlight that while graphs representing 2 CS were majorities in each textbook (all over 60%), graphs representing three or more RFs were also common across all the textbooks we examined. Graphs representing 4 or more RFs were less common, but present in fields that have an explicit focus on engineering and physical sciences (Chemical engineering; Engineering Statics; Material Science).

Table 2: Number of Reference Frames Identified in Each Graph (and as Percent of Graphs in that Textbook)

Textbook	2	3	4+
Agriculture	45 (94%)	3 (6%)	-
Statics	180 (61%)	86 (29%)	28 (10%)
Chem Eng.	84 (68%)	33 (27%)	6 (5%)
Astron.	107 (71%)	44 (29%)	-
Environ.	109 (85%)	19 (15%)	-
Material Sci.	74 (66%)	22 (20%)	16 (14%)

Table 3 presents our analysis across two dimensions of the RFs present in graphs which were coded independently. With respect to types of CSs, and consistent with findings from Paoletti et al. (2020), graphs were represented on quantitative CS in the vast majority of textbooks. Mechanic Statics was an exception with all graphs represented on Spatial CSs. The Astronomy textbook included a higher mix of Quantitative (70%) and Spatial RFs (28%). With respect to continuity or ordered-discrete RFs, the majority of graphs represented continuous quantities, with the Agriculture textbook being an exception (only 31% of graphs representing continuous quantities). Hence, across textbooks, quantitative CSs representing continuous quantities are most common, but graphs on spatial CSs or graphs representing OD quantities are important for particular STEM Fields (Statics and Agriculture, respectively).

Table 3: Number of Graphs Categorized by Types of RFs and Types of Quantities (and as Percent of Graphs in that Textbook)

	Types of RFs			Types of Quantities	
Textbook	Quantitative	Spatial	Both	Continuous	One or OD
Agriculture	47 (98%)	1 (2%)		15 (31%)	28 (58%)
Statics		294 (100%)		294 (100%)	
Chem Eng.	123 (100%)			121 (98%)	2 (2%)
Astron.	106 (70%)	43 (28%)	2 (1%)	149 (99%)	2 (2%)
Environ.	124 (97%)	4 (3%)		113 (88%)	15 (12%)
Material Sci.	112 (100%)			109 (97%)	3 (3%)

For space reasons, we do not present a table showing our analysis of the types of conventional CS. We note in several books (Agriculture, Statics, Environ., and Material Science), the vast majority of graphs were represented on Cartesian coordinate systems (between 87-100%). However, in the Chemistry Engineering and Astronomy textbooks, Cartesian coordinate systems were common (52% and 48% respectively); in these texts, Logarithmic axes (35% and 19%) and mixed axes (12% and 7%) appeared often. The Astronomy text also included 24% of graphs coded as other, which consisted of 3D schematic representations of the celestial sphere that lack explicit coordinate scales or quantitative statements on variables, focusing instead on illustrating spatial geometric relationships.

Table 4 presents the visually salient features of the graphs. Recall that in this category, a graph can have more than 1 visually salient feature. With the exception of the Statics textbook, lines within a graph were visually salient in 60% or more of all graphs. In many cases, it was also common for textbooks to include lines to axes, likely to support students in interpreting the graph accurately in relation to the quantities represented on the axes. Outside of this commonality, we highlight that the textbook's subject likely influenced which features were typically visually salient. The Astronomy textbook included numerous points to represent the locations of objects (e.g., planets). Similarly, all graphs within the Statics textbook represented vectors (100%), typically shown in relation to a physical object (51%). Hence, while certain visually salient aspects of graphs were common across fields, each field's particular content likely influenced the visually salient features they included within a graph.

Table 4: Number of Graphs Coded as Having Different Types of Visually Salient Features

Text book	Points	Lines in Graph	Regions	Bars	Vectors	Lines to Axes	Physical Objects
Agric.	4 (8%)	29 (60%)	8 (17%)	15 (31%)		6 (13%)	2 (4%)
Statics					294 (100%)		149 (51%)
Chem.	11 (9%)	117 (95%)	11 (9%)			108 (88%)	8 (7%)
Astr.	110 (73%)	128 (85%)	3 (2%)	1 (1%)	2 (1%)	45 (30%)	81 (54%)
Env.	35 (27%)	108 (84%)	39 (30%)	3 (2%)	4 (3%)	54 (42%)	7 (5%)
MS.		109 (97%)	7 (6%)	3 (3%)		109 (97%)	

Discussion

Addressing our RQ, we identified similarities and differences in graphs used across STEM fields. Generally, it may feel safe to say graphs with lines representing two quantities on Cartesian CSs are the most common graphs students are likely to experience across STEM fields. The fact that such graphs are common in US curricula textbooks (e.g., Lee & Guaradjo, 2023; Paoletti et al., 2020) may lead some to conclude that we are adequately preparing students to interpret graphs across STEM fields. However, we caution that such a conclusion may miss several nuances in how graphs are used both in US curricula and across STEM fields.

First, we highlight that given the majority of graphs (implicitly or explicitly) require students to reason about the ways two quantities covary, and such reasoning is not explicitly promoted in US school mathematics (Thompson & Carlson, 2017). This finding leads us to echo the calls of others (e.g., Gantt et al., 2023; Panorkou & Provost, 2025; Thompson & Harel, 2021) for the importance of covariational reasoning for students' success in STEM fields. The findings presented here underscore how critically important covariational reasoning is across STEM fields and the need for policymakers and curricular designers to make covariational reasoning a central part of US school curricula.

Second, given that US students are rarely asked to reason covariationally, even fewer opportunities exist for them to reason about *more* than two quantities changing despite showing such an ability as early as middle and high school (Bagossi, 2024; Panorkou & Germia, 2023). Given the high prevalence of such graphs across several STEM fields, we encourage future researchers to explore the potential efficacy of supporting younger students in making sense of graphs representing three or more quantities. Such reasoning can build on the research exploring students' covariational reasoning.

Third, while most graphs represent quantitative RFs, spatial RFs played a large role in the Engineering Mechanic Statics textbook. The fact that only 1 textbook uses such graphs may lead some to conclude that we should deemphasize such graphs in school mathematics. However, we highlight that Engineering Mechanic Statics is an introductory course for numerous engineering degrees. As such, if we expect students to succeed in their engineering coursework, we should provide them opportunities to construct meanings for graphs as representing spatial RFs. Further, given the ways US school math uses both quantitative and spatial RFs interchangeably (Lee & Guaradjo, 2023), we contend that supporting all students in becoming explicitly aware of the differences between the two types of RFs would support them in developing meanings for graphs more applicable across all STEM fields.

Our analysis presents an important first step in describing ways that graphs differ within and across STEM fields. Our analysis of visually salient features within a graph highlights how disciplinary content and practices (Roth & Bowen, 2023) play a key role in what visually salient features a graph includes. Further, our framework proved useful in categorizing a variety of features of graphical representations across STEM fields. Our analysis was limited as none of the research team has disciplinary knowledge that spans various STEM fields. Future researchers may be interested in exploring the ways faculty actually use such graphs in undergraduate STEM instruction, including how they expect students to interpret or construct such graphs. Such research can support mathematics policy makers and curricular designers in updating US school mathematics to reflect the types of knowledge required for student success in STEM fields. Such curricular materials could both increase the number of future STEM professionals.

This paper centers on empirical results that highlight how plausibly distinct pattern-based items (PBIs) are in what they assess when compared with standard or legacy items. The latter are taken to include items associated with high-stakes or large-scale testing and are currently developed using item response theory (IRT) or Rasch methods. Examples of legacy items are those appearing on the State of Texas Assessments of Academic Readiness (STAAR). We highlight a test-reliability metric and expectations regarding cross-item correlations to set out the contrast. While empirically informed, this paper presents a largely theory-centered account of how the continuing enactment of tests based on a notion of ability or a latent-trait will retain aspects of ineffectiveness and inequity that have been there from the start. The contrast with PBIs may serve to highlight that there are alternatives to continuing this legacy.

Keywords: Assessment, Learning Theory, Policy, Research Methods

When students engage with a mathematical task, they bring strategies, prior knowledge, distinct forms of communication, and emerging ideas to bear. Current standardized tests typically reduce this complex of varied reasoning and forms of engagement to a binary of right versus wrong. Our paper presents an alternative assessment approach that makes visible an array of instructionally relevant distinctions. The alternative centers on the use of pattern-based items (PBIs) or pattern-based questions (PBQs). To make the case that the use of pattern-based items is an alternative, we look to place in sharp relief the contrasts with current, or what we will call "legacy," large-scale, often high-stakes, standardized assessments that currently play a significant role in public education in the United States (and, indeed, around the world).

To make this case, we draw on results from the STAAR Interim Assessment Program (IAP, 2018–2019), in which PBIs were administered at scale across grades 3 through 8 in Mathematics and grade 5 in Reading at the request of the Texas Commissioner of Education. We focus specifically on two technical metrics—Cronbach's Alpha and cross-item correlations—not to evaluate PBIs by legacy standards, but to use the contrast those metrics reveal as a lens into fundamentally different assumptions about what assessment is for. Where legacy tests are designed to maximize consistency across items, producing a single scale score meant to index a latent trait, PBIs are designed to surface the diversity of student thinking, making the reasoning students bring to their work visible and usable at scale. Critically, we argue that the technical standards used to judge legacy tests are not neutral measures of quality—they encode assumptions about the fixedness of student ability that carry equity consequences.

A Focus on Patterns

Tests like the State of Texas Assessments of Academic Readiness (STAAR)—a mandatory program covering Texas public school students in grades 3 through 8, as well as specific high

school end-of-course classes—are built on a fundamentally different logic than pattern-based assessments. Using methods drawn from item response theory (IRT) and Rasch modeling, legacy assessments are designed to produce a single, consistent score that places each student on an ability scale. The technical standards that define a "good" test in this tradition reward consistency. Items that do not align with the ability scale are removed. As a result, the instrument will tend to be optimized for ranking students rather than illuminating specific features of their understandings.

The difference between these two approaches is not merely technical. The norms embedded in standard psychometric practice—particularly the reliance on internal consistency as a measure of test quality—carry assumptions about student ability that trace their roots to the earliest days of what is now called psychometrics, or "mind measurement." As will be discussed, from early on its inception, this tradition treated intellectual capacity as a fixed, ranked quantity: something a student either had more or less of, and that a well-designed test could reliably detect. As will be discussed, Alfred Binet, whose work gave rise to the modern intelligence test, came to explicitly critique aspects of this view, insisting that intelligence was not "a fixed quantity that cannot be augmented" (1909, pp. 105-106). Yet the institutional apparatus that grew from his methods did precisely that, building tests designed to sort students into stable ability categories and building metrics that advanced tests optimized for sorting. We argue that continuing to assess student understanding through this framework reproduces both the ineffectiveness and the inequities that have characterized that tradition from the start.

An Example of a Pattern-Based Mathematics Item

Figure 1 shows an equivalent-fraction related pattern-based item that was administered at scale (N=60,517) as part of the State of Texas Assessments of Academic Readiness (STAAR) Interim Assessment Program (IAP 2018-2019). Pattern-based items were included in the STAAR IAP for grades 3 through 8 in Mathematics and grade 5 in Reading at the request of the Commissioner of Education (Stroup, 2020; Stroup et al., 2023; Stroup, 2024; Stroup, 2025). Like most of the items developed for, and then implemented on, the IAP, the alignment of this question with the Texas Essential Knowledge and Skills curricular standards was maintained by retaining essential elements of a released multiple-choice STAAR item, including, as is illustrated in this case, the use of specific language like "shaded to show equivalent fractions" (Texas Education Agency [TEA], 2018 Grade 3 p. 12).

Visual similarity to traditional or "legacy" multiple-choice or multi-select items notwithstanding, the development of the prompt and the responses is designed to reveal instructionally relevant patterns in students' understandings related to specific curricular standards (e.g., equivalent fractions). Unlike legacy multi-select questions, which also may have more than one correct response for students to endorse, pattern-based items are designed to make use of the full combinatorial space of responses.

Analogous to possible combinations of four notes on a keyboard, there are 16 possible combinations of the four responses (A–D) that are made available to identify the relevant patterns. By excluding the no-response category, we use 15 states in our analyses. These analyses include frequency plots of the 15 combinations for each item, sorted (at the request of the teachers we've worked with) from low to high according to a matching, True/False-type, partial-credit model.

The combination ABC, shown at the right in the frequency plot in Figure 1, receives full credit for this item by matching the three correct responses (the three "True" responses) and *not* selecting the one incorrect (or "False") response.

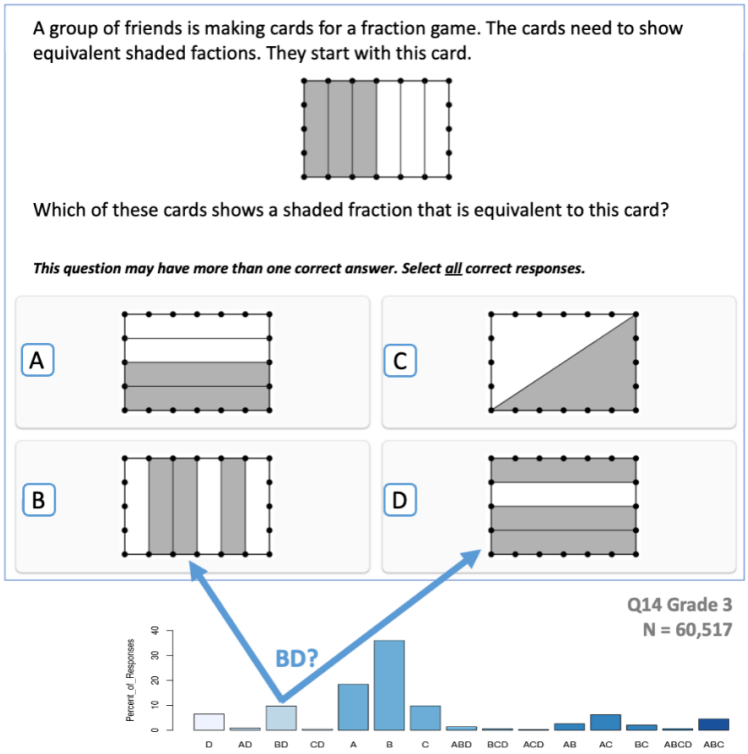

Figure 1: The Pattern of a Correct Response B Combined with an Incorrect Response D Suggests Students are "Counting Pieces."

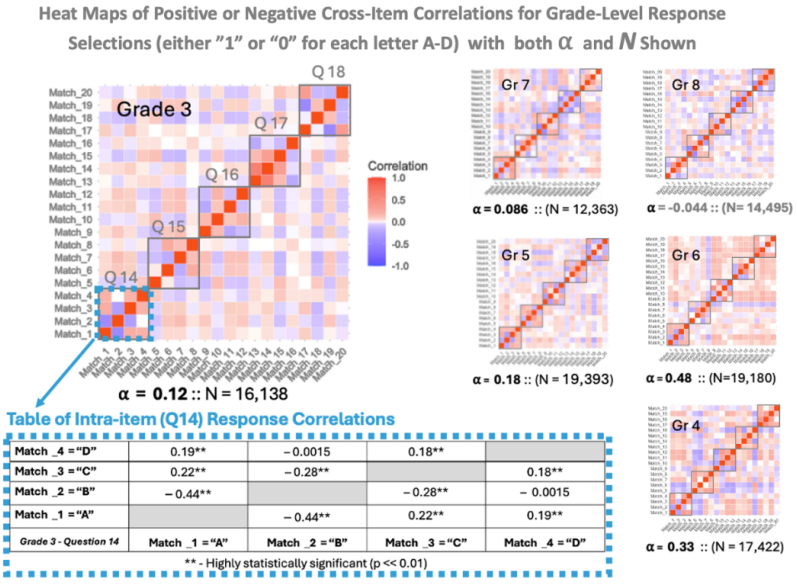
To illustrate the importance of going beyond simply tallying how many times students selected each response (A, B, C, or D), we have highlighted the BD combination in the frequency plot. B is a shaded region that is an equivalent shaded fraction of a whole card. D, in contrast, is not an equivalent area. The question might become, what does this combination of a correct response and an incorrect response suggest about the students' understanding?

As reported in previous work (Stroup, 2020; Stroup, 2024; Stroup, 2025), the elementary teachers we have worked with have maintained that students are "counting pieces" without reference to the fraction of the whole the pieces represent. Further, they reported that counting pieces is a way of thinking about fractions that they regularly encounter in their work with students. This is precisely the kind of instructionally actionable insight that a scale score cannot produce: not that those students answered incorrectly, but that they are applying a specific, recognizable strategy that has a known relationship to the target concept and that can inform an instructional response.

Moreover, implicit in the use of scale-score reporting of assessment results is the sense that there is a consistently interpretable "something" that is being measured on that "scale" of something. This something is to be accessed through the specific use of a collection of scale-consistent items that make up a test. This focus on consistency, or what we'll call *homogeneity*, contrasts with the pattern-based approaches' focus on characterizing and engaging with the *diverse* understandings students may have regarding specific topics in the state standards, as made visible by analyzing the distinct combinations in their response selections for a given item.

Contrasting Homogeneity with Diversity Using Cronbach's Alpha and Correlations

Cronbach's Alpha (CA) is a widely deployed measure of the internal consistency of items appearing on a given test. Historically, CA (or the mathematically equivalent Kuder-Richardson 20 [KR20] test for dichotomously scored items) has been taken as a measure of a test's reliability. While we recognize this usage, we suggest a normative interpretation is implicit in the use of the word "reliability" that goes beyond what is warranted by what is a measure of internal consistency. The distinction matters partly because reliability, strictly defined, refers to whether repeated administrations of the same instrument produce consistent results. Internal consistency, by contrast, measures whether items within a single test administration align or cohere. Conflating these two properties imports an assumption that a good test must measure one coherent thing, which is precisely the assumption PBIs are designed to challenge. We certainly allow that values for CA (or KR20) approaching an upper value of "1" can be interpreted as indicating a high level of internal consistency. Rather than add the normative use of reliability, however, we suggest that the consistency associated with high CA values is a measure of the *homogeneity* of the items.



In a related way, positive correlations between results on individual items are associated with the homogeneity also associated with relatively high values for Cronbach's Alpha. The normative assumptions traditionally associated with high CA results are problematic when compared with results from analyzing responses to pattern-based items, such as the PBIs deployed on the STAAR Interim Assessment Program in Texas. The identification of distinct patterns relies on items that make visible contrasts in forms of student understanding. The ability to identify meaningful patterns relevant to instruction—e.g., the results shown above, which can inform educators that a number of students may be counting pieces rather than referring to a unit whole in determining fractional equivalence—is an important component in establishing the warrant for using pattern-based approaches to assessment.

What we might expect, then, is that measures of internal consistency, as well as cross-item correlations for response selections, would reflect this effort to specify the *diversity* of students' understandings. The values for CA would be low (or even negative). Moreover, correlations between students' response selections could be positive or negative, and, at scale, could be statistically significant ($p<0.05$) or highly statistically significant ($p<0.01$). This focus on identifying *diversity* we see as contrasting substantially with the use of *homogeneity*, as normative, in evaluating both tests and individual items.

To setup and frame the contrast with pattern-based items shown in Figure 2, it is worth first discussing the analyses of homogeneity associated with STAAR tests. The normative interpretation of relatively high CA or KR20 values is maintained in the technical digests prepared annually in Texas for the STAAR tests. Internal consistency coefficients "ranging from 0.70 to 0.79 are considered adequate, those from 0.80 to 0.89 are considered good, and those at 0.90 or above are considered excellent" (TEA, 2022, p. 31). In practice, the coefficients for the tests in each grade ranged from "0.84 to 0.92 for the primary STAAR English and STAAR Spanish assessments administered in spring 2022" (TEA, 2022, p. 31) Overall, the end-of-course tests had "reliability estimates" ranging from 0.91 to 0.94 (TEA, 2022, p. 31). Positive correlations between item scores would be expected. CA or KR20 values below 0.7 would be considered inadequate, and those below 0.5 would be considered completely unacceptable as coefficients taken to measure test homogeneity.

Using the same metrics, now framed to assess the complexity and diversity of students' understandings, the contrasts in our results for the pattern-based mathematics items used on the

IAP, shown in Figure 2, are striking. Using "1" to represent selecting a response and "0" to represent not selecting a response, as extended to 20 responses (four letter choices for each of five items), a "heat map" is shown for the correlations of each response with the other responses. The shading intensity depicts the relative strengths of positive and negative correlations. In general, the shadings and associated values for the positive and negative correlations are relatively faint, except for responses within a given item. The squares across the heat maps denote areas of intra-item correlation, with the associated shading intensities, representing higher values for both positive and negative correlations, more intense.

Match _4 = "D"	0.19**	−0.0015	0.18**	
Match _3 = "C"	0.22**	−0.28**		0.18**
Match _2 = "B"	−0.44**		−0.28**	−0.0015
Match _1 = "A"		−0.44**	0.22**	0.19**
Grade 3 - Question 14	Match _1 = "A"	Match _2 = "B"	Match _3 = "C"	Match _4 = "D"

Figure 2: Using Chronbach's Alpha and Correlations to Highlight How Pattern-based Items Highlight Contrasting Diversity of Student Responses at Scale

The actual values of the intra-item correlations for the equivalent fractions item (Figure 1) are shown in the table at the bottom of the figure. Note that the correlations are both positive and negative and that almost all these varying values are highly significant ($p<0.01$). This pattern—strong, mixed-sign correlations within items and weak correlations across items—is what one would expect from an instrument designed to capture the diversity of student thinking within each conceptual domain, while making no assumption that performance on one standard necessarily predicts performance on another. To attend to the diversity of student understandings, the contrasts between responses are intended to be most significant within each item.

The contrasting expectations regarding inter- and intra-item correlations at each grade level do, as expected, have implications for computed consistency coefficients. When the consistency coefficients are computed for the responses at each grade level (we used Cronbach's Alpha), the values are generally very low, typically well below 0.5, and in one case even slightly negative. Clearly, PBIs do not do well when assessed normatively in terms of cross-item and test-level homogeneity. This is by design. The question of whether to continue using assessments focused on homogeneity to maintain relative rankings of students, or to use assessments centered on engaging the diversity of student understandings, need not be decided by biasing the selection based on contrasting expectations for what statistically rendered comparisons can or should show.

More relevant might be which approach does a better job of assessing students in ways that provide insights into students' understandings of distinct curricular standards. Moreover, as is taken up in the next section, the choice can center on contrasting implications for equity.

Homogeneity in Relation to Equity

Susan E. Embretson in her William H. Angoff Memorial Lecture presented at Educational Testing Service in January of 2001 (Embretson, 2003) titled *The Second Century of Ability Testing: Some Predictions and Speculations* makes the case in her "overview of the last century" that the "most fundamental principles in psychometrics and testing were available by 1930" (p. 5). Then "[w]ith a few notable exceptions, the remainder of the last century of testing was devoted to applying or refining these principles" (p. 5). How does a focus on creating cross-item homogeneity draw on specific features of "ability" testing that Embretson sees as carrying forward from the early 20th century into the present?

Her account is largely historical, including the identification of Alfred Binet as a pivotal figure in the development of what were to become the fundamental principles of psychometrics. Rather than focus on low-level skill development, one of Binet's contributions "is the use of higher-order cognitive tasks to measure intelligence" (Embretson, 2003, p. 8). Referencing the works of Binet and Binet and Simon (1905, 1908, and 1911), Embretson discusses "Binet's global conceptualization of intelligence," where "empirical criteria" would be used to "select intelligence test items" (p. 8). Binet's two criteria were to be that "task performance should increase with age" and "task performance should be related to school achievement" (p. 8).

In the present, we might want to distinguish between tests of achievement and tests of intelligence or aptitude. This expectation notwithstanding, the explicit linking of what would appear to be tests of "school achievement" to intelligence or ability testing is central to understanding the development and the requirements for current scale-score reporting of test results. Embretson summarizes some of these features:

> An interesting feature of Binet's system is that items and examinees are placed on a common scale. That is, both items and examinees are referenced to mental age. Tasks were scaled for mental age from empirical data on the performance of children at various ages. Examinees were scaled for mental age by their relative success in solving the age-calibrated tasks. Due to the age-calibrations of the tasks, examinees may be compared even if they do not receive the same items. (p. 8)

Much of what is outlined is part of accepted current practices in item and test development. Homogeneity for items serves in relation to placing examinees on "a common scale." Tasks are to be "scaled," using "empirical data." as a form of "mental age" taken to be analogous to the growth associated with physical maturational, or age-referencing, traits like height (see left-most graph from the Center for Disease Control in Figure 3 [NCHS, 2000] with an overlay of a child's trajectory along an expected growth curve). And once the specific "age-calibrations" of tasks are determined, examinees do not have to "receive the same items" to be compared.

Based on the features of the growth curves, there is no expectation that one's age-referenced ability would change relative to the age referencing of other students. The sense is that normal growth would be a child remaining in their relative position until they mature (as shown in Figure 3, the curves flatten out). Relatively tall children would be expected to become relatively tall adults; less tall children would be expected to become less tall adults. The WISC IQ growth curve is included to reinforce the sense that tests of what might look like "school achievement" can, in fact, as Binet is said to have outlined, serve a "global conceptualization of intelligence."

Figure 3 is meant to summarize and illustrate the intended parallels between expected growth relative to other children for physical traits (height), the development of mental ability (now typically reported as an intelligence quotient [IQ] of mental age/actual age*100) and graphs of actual age-specific scale score results for tests from one of the largest, achievement referencing, school-aged test vendors in the United States (NWEA, 2026, p. 8).

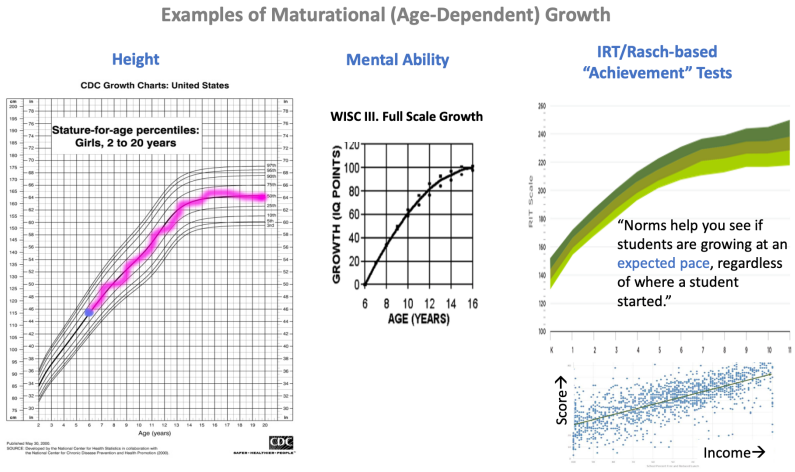


Figure 3: Similarity in Graphs of Height, IQ and "Achievement" Results.

The continuity with the "Fundamental principles in psychometrics and testing" reaching back to Binet and embraced by those wanting to treat intellectual capacity or ability as a heritable trait analogous to biological traits like height becomes clearer when the vendor states, "Norms help educators see if students are growing at an expected pace, regardless of where a student started" (NWEA, 2020). The implications for equity are demonstrated by the vendor's own analysis of scale score as a function of income (shown at the lower right of Figure 3; NWEA, 2018, p.8). Disaggregated results for other tests based on the same fundamental principles show a similar tendency to treat comparatively low (or high) outcomes for particular groups of students as normative and therefore expected.

Embretson's account of the rise of psychometrics elides the fact that Binet came to be deeply troubled by what was being done with his work in ways that fully anticipate the kind of results summarized in Figure 3. Binet observed that:

> Some recent philosophers seem to have given their moral approval to these deplorable verdicts that affirm that the intelligence of an individual is a fixed quantity, a quantity that cannot be augmented. We must protest and react against this brutal pessimism; we will try to demonstrate that it is founded on nothing. (1909, pp. 105–106)

The "brutal pessimism" that Binet identifies is centered on the idea that "intelligence" is a "fixed quantity" of an "individual."

Binet's concern notwithstanding, Embretson outlines how "the remainder of the last century of testing was devoted to applying or refining these principles" (p.5) in ways that are illustrated by Figure 3. Indeed, the educational psychologist Howard Gardner and his colleagues summarize the transformation by suggesting the "discovery of *g*," taken as "general intelligence as defined by psychometricians," and the "statistical analyses related to *g* are the most compelling findings and contributions of psychology" (1995, p.58). The contrast between possible measures of

student achievement and measures of "aptitude" now appears to have been collapsed, with achievement tests functioning as *de facto* measures of individual and, by extension, group intelligence.

Arthur Jensen (2000) embraces this possibility: "When the applicant pool is homogeneous in amount of prior schooling, a comprehensive scholastic achievement test can reflect *g* as well as a conventional paper-and-pencil IQ test" (p. 126). Jensen's point is that emphasizing the apparent "face validity" of "scholastic achievement" tests (e.g., an NWEA MAP or a STAAR math assessment made up of items that look to be about mathematics) "need not harm either construct validity or predictive validity" (p. 126) relative to measuring *g* or what Binet called the "fixed quantity" of the "intelligence of an individual" (1909, pp. 105–106).

Implications for equity are foregrounded in that Jensen "put forth his view that racial differences in intelligence were genuine, were due significantly to hereditary factors, and were not much susceptible to remediation or erasure" (Gardner et al., 1995, p. 153). Jensen and his colleague J. Philippe Rushton summarize what they see as the trajectory for a focus on hereditary factors:

> More generally, there is a need to educate the public about the true nature of individual and group differences, genetics, and evolutionary biology. Ultimately, the public must accept the pragmatic reality that some groups will be overrepresented and other groups underrepresented in various socially valued outcomes. Organizations such as the APA could play a critical role in changing the zeitgeist. (2005, p.284)

It is reasonable to be concerned that tests evaluated in terms of homogeneity may end up advancing the effort to convince "the public" of the genetic or biologically determined "reality" that "some groups" with be "overrepresented" or "underrepresented" in a widely array of "socially valued outcomes" in ways that may include representing current tests results as measures of college and career readiness.

The low sensitivity of legacy scale scores to instructional variation has been documented elsewhere (*cf.* Polikoff & Porter, 2014). Because items are selected for cross-item homogeneity and scaled to stable ability distributions, tests optimized in this way will, by design, be resistant to detecting instruction effects related to specific standards. PBIs, by contrast, are aligned with curricular standards and are designed to detect shifts in the patterns of thinking students bring to those standards, making instructional effects visible.

The equity implications of ability-based psychometrics come into sharpest relief when results are tracked over time. A system built on the assumption that relative rankings are stable will produce graphs that look like growth curves—each cohort moving upward at roughly the same rate, with gaps between groups persisting or widening. This is what Figure 3 illustrates.

Diversity and Attending to Qualitatively Distinct Understandings

Perhaps because Jean Piaget (1972) framed his work as developing a "genetic epistemology" rather than contributing to the kind of psychometrics that emerged from the work of Binet, Embretson did not take up the broader implications of Piaget's work for assessment (*cf.* Stroup & Wilensky, 2000; Stroup et al., 2011). Nonetheless, early in his career, Piaget worked with Binet as Binet was developing his approach to intelligence testing. Anticipating his development of a theory based on significant, age-related changes in children's reasoning, Piaget became attentive to how, at each stage of cognitive development, the child's thinking is qualitatively different. Without committing to specific aspects of his stage theory, pattern-based questions similarly focus on qualitatively distinct forms of reasoning (see Figure 1). Moreover, as reported in

previous work (Stroup et al., 2023), when items developed for the IAP were implemented across grade levels, the results did not follow the "growth" curves shown in Figure 3. Some results went up; others went up then down; and for one item related to volume, the partial credit scores went down from grade 5 to grade 8. Teachers had explanations for this decrease (e.g., over-dependence on formulas in later grades) in ways that are seen as related to features of instruction.

This paper articulates a vision for mathematics education research that moves beyond paradigmatic arguments and towards a place that grounds mathematics education scholarship in a different space using robust methodologies and methods. Utilizing innovative quantitative, qualitative, and mixed methods have substantive opportunities to explore mathematics education topics. For example, validation is one methodology that draws from quantitative, qualitative, and mixed-methods research practices (Bostic, 2026). Additionally, we argue that doctoral graduate education in STEM education must prioritize learning a variety of research methods to prepare scholars for the methodological hybridity (Edelen et al., 2026) needed for 21st century research.

Keywords: Research Methods

Historically, there has been an "ongoing tug of war" (Campbell et al., 2025, p. 348) related to methods and methodologies. Broadly speaking, quantitative research answers questions that examine "what," "to what degree," and "how" (Creswell & Guetterman, 2019; Gay et al., 2012). Qualitative research on the other hand explores 'how' and 'why' questions that reify phenomena (Creswell & Guetterman, 2019; Gay et al., 2012). Mixed-methods research blends the best of both areas in a variety of ways (Creswell & Guetterman, 2019; Gay et al., 2012) and came about as a response to the aforementioned tug of war. For decades, there have been civil methodological arguments, which stemmed from a movement from a previously dominant paradigm in mathematics education scholarship and towards a more pluralistic approach to studying mathematics education issues (Inglis & Foster, 2018). These arguments often missed a key facet: The best methods are those that effectively answer a research question (Inglis & Foster, 2018; Schoenfeld, 2016). It is precisely for this reason that this manuscript's goal is to end arguments about what methods are better and incite what we refer to as a methodological rebellion for mathematics education scholars to learn educational, and even social science, research methods more deeply.

An Abbreviated Review of Mathematics Education Scholarship Through Methods

Prior to the 1980s, quantitative research dominated mathematics education scholarship (Bostic et al., 2019; Schoenfeld, 2016). There was the start of qualitative research being published, which helped to uncover new ideas and issues that were previously underexplored. An early example of qualitative research that has helped to shape mathematics education scholarship is "The case of Benny" (Erlwanger, 1973). Piagetian and Vygotskian ideas were taken up in scholarship, as seen in *Journal of Research in Mathematics Education* (JRME) and *Educational Studies in Mathematics* (ESM) publications (Schoenfeld, 2016). Qualitative research provided scholars with new methods and approaches that led to insights absent from quantitative research. The 1990s continued the trend with more qualitative research found in mathematics education publications. The 2010s had a small but growing group of scholars engaging in mixed-methods research (Campbell et al., 2025) that developed into the robust, grounded field that it is today.

Campbell and co-authors conducted an analysis of the JRME and ESM between 2014-2023. JRME is the flagship journal for the National Council of Teachers of Mathematics thus having a large North American presence. ESM is not associated with an organization yet it was started in

Europe. The ESM sample contained 462 empirical articles whereas JRME had 125 articles. Most of the ESM articles were qualitative in nature (52%), with mixed-methods coming in second (28%), and quantitative research was found the least (20%). Said another way, 241 qualitative studies were published compared to the 91 quantitative studies an almost 3:1 ratio! JRME had a more balanced profile with 38% of the sample defined as qualitative research, 35% of the articles had quantitative research, and 27% drawing on mixed-methods research. Looking at the research methods by global region highlights a similar trend. ESM authors in Europe, North America, South America, Sub-Saharan Africa, as well as Australia and Oceania tend to use qualitative methods more frequently than quantitative methods. JRME authors portray a more balanced profile with authors from these same regions demonstrating a balance of quantitative and qualitative methods. It was rare to observe within a region when mixed methods were leveraged as much or more than quantitative and qualitative methods.

A similar scoping study was done with integrated STEM education research to give some contrast to mathematics education scholarship. This study included 64 academic journals and a total of 746 empirical articles between 2020–2025 for the sample (Edelen et al., 2026). Results indicated that 52% of the scholarship was quantitative (n=392), 32% was qualitative (n=238), and 16% was mixed methods (n=116). Much of the quantitative research used a pre-/post-test approach that can omit variance during an intervention and very few used an experimental or quasi-experimental design. Quite a bit of the qualitative studies in this sample employed interviews alongside thematic or content analysis. These approaches are good but highlight a lack of methodological diversity across the article sample, which suggests that some richness from other methodological perspectives may be lost (e.g., ethnography, grounded theory, discourse analysis, and critical pedagogy). Among mixed-methods research, surveys and achievement data were the most frequently used data collection tools. Self-report data have been shown to be problematic (Akbulut, 2025), which necessitates careful consideration.

Taken collectively, this abbreviated review signals both growth and constraint within mathematics education and, and more broadly STEM education scholarship. The field has expanded methodologically across the past five decades, moving from quantitative dominance toward greater inclusion of qualitative and, to a lesser extent, mixed-methods approaches. Yet, patterns within publication trends suggest that methodological diversity remains uneven, with certain designs and analytic traditions taken up far more frequently than others. While the knowledge base has deepened, there remains missed opportunities to capture the full complexity of phenomena. The scholarly landscape underscores the need for methodological plurality and moreover, for scholars to be prepared to engage, combine, and extend methods in ways that illuminate dimensions of mathematics education that might otherwise remain obscured.

Mathematics Education Methods Preparation in Brief

A slightly different lens on mathematics education research is to examine scholars preparation in graduate school. Such examinations may illustrate potential opportunities. There has been some scholarship on doctoral mathematics education suggesting that 75% of the recent doctoral mathematics education graduates complete no more than two quantitative research courses during graduate school (Shih et al., 2019). Typically, descriptive statistics, ANOVA, and single-variable regression are included in such courses. Experimental designs are generally explored in later courses. On the other hand, the number of qualitative courses taken by mathematics education graduates is uncertain but over 90% of the sampled doctoral graduates felt their preparation in qualitative research methods was “adequate” or “very well adequate”. It was unclear what was in those courses; potential paradigms and philosophies may be overlooked.

Integrating those findings with Edelen et al.'s (2026) prior analyses of STEM education scholarship suggest that much published qualitative work relies heavily on interviews coupled with thematic or content analysis, pointing to a narrower range of qualitative approaches than the field might warrant. This raises questions about whether perceptions of adequacy align with the depth, rigor, and methodological diversity needed to sustain and extend qualitative inquiry in mathematics education. As Shih's team wrote about doctoral graduates' methodological preparation, "This finding is worrisome, as the lack of foundation in research methods is likely to several limit research activities" (2019, p. 24).

If mathematics education scholarship seeks to build upon its extant foundation, as well as leveraging findings from fields that also conduct mathematics education research (e.g., psychology, integrated STEM education, policy, and assessment), then it is absolutely necessary that graduates are fully prepared to confidently understand at least one area, which may allow them to design, conduct, and report results from their research. And if this was not concerning enough, these findings do not report on doctoral graduates' understanding of mixed methods; an area that has grown tremendously in the last decade. For these reasons, it may be useful to reflect further on what is important in graduate education and to foster longevity of mathematics education. One viable outcome is to consider a methodological rebellion aimed at strengthening how graduates and current scholars are prepared to engage with educational research methods.

A Proposal: Let's Become Rooted in Educational Research Methods

Mathematics education scholarship is wide and deep, which is both an opportunity and a challenge. There is no possible way for a scholar to know all of it deeply; however, it is fair to expect a scholar to know at least one area deeply and to have a broad understanding of major mathematics education topics (e.g., teacher education and student learning) in some capacity. Similarly, it is not feasible to know all research methods deeply, as with mathematics education topics, a scholar could capably know quantitative, qualitative, or mixed methods deeply. Lacking expertise in one or more area opens space for collaborations with others who might be an expert in that area. Building collaborations with research methodologists helps to synergize different forms of expertise. A mathematics education researcher, working alongside a methodologist, should feel confident collaborating and be able to verify and/or understand the methods and outcomes from such work. Leaving interpretations or evaluations entirely to a methodologist may lose the richness that could only be found from a mathematics educator who can interpret results in context.

Hence, we argue that scholars in mathematics education must cultivate both depth and discernment when it comes to research methodologies and methods. From our perspective, depth anchors a scholar's intellectual identity in research; discernment allows one to engage responsibly beyond one's primary area of expertise. When collaborating with research methodologists, mathematics education scholars should not cede their epistemic, or even ontological responsibility. Rather, we should enter dialogue in which methodological rigor and disciplinary insights inform one another in a symbiotic relationship. A mathematics educator should be able to interrogate methodological choices, understand analytic decisions, and interpret findings in light of the histories, practices, and logics of mathematics classrooms. Without such a reciprocal engagement, methodological precision risks becoming detached from educational meaning in mathematics education research. Productive collaborations, then, move beyond divisions of labor to being co-constructed spaces of inquiry in which methodological expertise and mathematics education knowledge work together to generate claims that are both technically sound and educationally illuminative. Building from this stance, recent scholarship in STEM

education has begun to more explicitly name what methodological depth and discernment might be helpful for future STEM education research. Edelen and co-authors (2026) advocated for a greater understanding of the differences between methodology and method, which could foster more diversity of qualitative, quantitative, and mixed-methods approaches. A goal is to embrace the methodological hybrid nature to capture the complexities of learning, which means building greater methodological preparedness among scholars and working collaboratively. QuantCrit is one approach that is often ignored in STEM education (Young et al., 2025). Validation (Bostic, 2026) draws upon quantitative, qualitative, and mixed-methods approaches. Ethnographic work draws on interactional and historical analyses to examine how learning is co-constructed in practice and to focus on how learners make meaning visible (Walford, 2020).

Yet, this vision raises an important question: Are we, as mathematics education scholars, being prepared, preparing others, and preparing ourselves to participate meaningfully in such collaborations? More directly, do we possess the depth and discernment necessary to engage in methodological discussions as intellectual partners in the shared construction of knowledge?

Final Thoughts

One goal from this manuscript is (a) to end arguments trying to prove one research method is better and (b) to give some overview of mathematics education scholarship. A second goal is to highlight the opportunity for current scholars—especially graduate students and post-doctoral scholars—to value all methodologies and methods and to become deeply knowledgeable with the diversity and hybrid approaches to educational research. By deepening knowledge of methodologies and methods, there is potential for generating and leveraging modern approaches that effectively capture variance and/or wholly capture the essence of a phenomenon.

CONCEPTUALIZING AND APPLYING A TASK ANALYSIS FRAMEWORK

Jeffrey Choppin

We applied a task analysis framework that characterized tasks according to their ambiguity and potential to make connections, in the process providing nuance with respect to mathematical activity and tools entailed by the task. We proposed four forms of mathematical activity that increased in their ambiguity and potential to make connections and created a matrix that detailed descriptions of these activities according to different types of mathematical tools. Based on middle school mathematics topics, we identified three types of tools: mathematical terminology and formulas, procedures and algorithms, and representations. We analyzed tasks from three different curriculum programs to test out the framework and to see what insights could be generated by its use. The goal is to provide specificity when analyzing tasks that has face validity for both researchers and practitioners.

Keywords: Curriculum, Mathematical Representations, Instructional Activities and Practices

We propose a framework to characterize tasks in middle school mathematics curriculum. The proposed framework builds from and expands on task analysis framework of Stein et al. (2009) that has been widely utilized to characterize mathematical tasks, especially in the US context (cf. Cai et al. 2009; Tekkumru-Kisa et al., 2020). The Stein et al. framework has four levels of task ratings, of which two are considered low cognitive demand and two are considered high cognitive demand. The low cognitive demand categories are memorization and procedures without connections, while the high cognitive demand categories are procedures with connections and doing mathematics. We argue additional nuance is needed with respect to the nature of mathematical activity and tools entailed by tasks, especially for secondary mathematics content. We describe the tenets of our framework and present results from the analyses of several curriculum programs. The potential contributions of the paper are methodological and theoretical in relation to studies of curriculum design and enactment.

Our framework builds from the perspective that curriculum materials entail two communicative functions, monologic and dialogic (Choppin et al., 2015; Choppin et al., 2022). We argue that tasks that are routine mostly adhere to the monologic communicative function while tasks that are non-routine mostly adhere to the dialogic communicative function. Non-routine tasks have the potential to generate idiosyncratic and varied approaches or ways of reasoning; these different approaches or ways of reasoning in turn afford opportunities for students to generate meaning (e.g., thinking devices) when their differences and similarities are made explicit and provide opportunities to develop new knowledge in a community. We characterize non-routine tasks largely by their ambiguity, their potential for making connections, and their potential for multiple approaches. Instead of the term cognitive demand, we use notions of ambiguity and connections to distinguish between routine and non-routine tasks. Below, we elaborate the framing around the dialogic potential of tasks and then present the framework.

Proposed Task Analysis Framework

We extrapolated two essential characteristics that distinguish low and high cognitive demand categories in the Stein et al. (2009) framework. The first essential characteristic is the ambiguity of the task, especially in terms of whether an approach or formulation is specified. The lack of

specificity of an approach invokes the need for strategic flexibility so that students must make decisions about what concepts and processes are relevant to a task (Doyle, 1983; Stein et al., 2009). The second essential characteristic is the potential for students to make connections; the two primary types of connections are (1) connections between procedures and concepts and (2) connections between different types of representations (Stein et al., 2009). The categorization we propose emphasizes these characteristics and connects them to forms of mathematical activity and mathematical tools entailed by tasks, which provides greater specificity when characterizing learning opportunities tasks afford, especially regarding secondary mathematics content.

We define mathematical activity as a process by which students engage with mathematical content represented in tasks. We propose the following four activity categories that entail increasing ambiguity and potential for connections: following established processes and recalling terminology, applying mathematics to contexts, demonstrating flexible use of tools, and generating conceptual understanding. The category following established processes and recalling terminology applies to tasks with minimal ambiguity or potential for connections in which students are expected to recall or use established procedures or terminology. The category applying mathematics to contexts applies to tasks that require students to apply or describe terminology or procedures in ways that require some interpretation of the context. The category demonstrating flexible use of tools applies to tasks that involve choices regarding terms, procedures, or tools that can be used, requiring students to make strategic decisions about an approach. The category generating conceptual understanding applies to tasks that involve developing/applying terminology or procedures in novel ways or explaining novel relationships between concepts. We use the term novel to indicate engagement with mathematical content in ways that students have not previously explored or encountered or may be unconventional.

In addition, we identified the mathematical tools that are embedded in tasks to add specificity to our descriptions of mathematical activity, with different tools entailing different ways students engage with mathematical content for each type of activity. These tools, based on middle school mathematical content, include mathematical terminology and formulas, procedures and algorithms, and representations. Identifying tools allows us to provide more fine-grained descriptions of the ways tasks influence how students engage with mathematical content. See Table 1 for a matrix of the intersection between mathematical activities and mathematical tools.

Table 1: Matrix of Mathematical Activity and Mathematical Tools

	Mathematical Activity (increasing ambiguity and potential for connections from left to right)			
Mathematical Tools	Following established processes and recalling terminology	Applying mathematics to contexts	Demonstrating flexible use of tools	Generating conceptual understanding
Mathematical terminology and formulas	Memorizing or recalling basic facts, definitions, or formulas.	Applying or explaining facts, definitions, or formulas in new contexts	Selecting or explaining facts, terminology, or formulas when multiple possibilities exist.	Developing or applying terminology or formulas in novel ways OR explaining novel relationships between concepts
Procedures and algorithms	Accurately and efficiently carrying out established procedures OR explaining how to do so.	Applying or explaining established procedures in new contexts.	Selecting or explaining procedures or algorithms when multiple possibilities exist.	Developing or applying procedures or algorithms in unconventional or novel ways.
Representations	Generating representations with a well-established method OR identifying information in a representation without having to interpret a context	Generating a representation that involves a context OR identifying information from a representation that requires interpretation of the context.	Identifying or explaining mathematical relationships from representations when multiple possibilities exist OR generating representations when multiple possibilities exist.	Developing or using representations in novel ways OR interpreting representations in unconventional or novel ways.

In Table 1, the level of ambiguity in mathematical activity increases from left to right, with the leftmost two forms of mathematical activity involving minimal ambiguity and are considered routine. By contrast, the rightmost two involving higher levels of ambiguity and are considered non-routine. We define ambiguity in terms of a lack of prescribed approaches, such as a procedure previously modelled or terminology that has been formally defined. Ambiguity entails having flexible options from which to choose in terms of tools, requiring students to make and explain choices regarding their approach. We also note that the rightmost columns can subsume some of the properties of the leftmost columns, such as when problems involve applying

mathematics to contexts in ways that involve more ambiguity than what is indicated in the applying mathematics to contexts column.

Applying the Framework

We applied the framework to characterize tasks in three different curriculum programs. Using the cells in Table 1 as a codebook, we coded at the level of task. We delineated a task when there was a distinct set of requirements from tasks that preceded or followed. Occasionally, we grouped tasks if there was a set that had a closely related set of requirements (e.g., students were expected to do the same thing or very similar thing with each task in the set). To maintain the exclusivity of the categories for mathematical activity, we required that each coder only apply a single activity code. The activity categories are what distinguishes tasks according to their ambiguity and potential for connections, which are the essential task characteristics identified in our framework as well as the Stein et al. (2009) framework. The dimension of mathematical tools allows us to create fine-grained descriptions of mathematical activities for each type of tool, providing a greater likelihood that the descriptions have face validity with researchers and practitioners. For mathematical tools, we allowed coders to apply up to two tool codes after we observed that many tasks employed multiple tools according to our descriptions. To achieve consensus, we met synchronously via Zoom to reconcile differences. We began by reconciling the mathematical activity and then reconciling the tool codes, an order that mirrored the prioritization of mathematical activity as the more important distinguishing characteristic. We iteratively revised the table over the course of reconciling the first two curriculum programs to increase clarity and comprehensiveness, leading to the version in Table 1.

Discussion

We developed and applied a curriculum framework to provide greater specification of the nature of tasks in contemporary curriculum materials at the secondary level. The framework employed a codebook (Table 1) to engage in low-inference coding of tasks so that the results would have face validity to both practitioners and researchers. The consensus process demonstrated the need for ongoing refinement of Table 1 and led to productive discussions that we hope will lead to increased reliability and confidence when applying the framework.

The mathematical activity categories provide important distinctions between mathematical processes and tools tasks require of students, especially in relation to secondary mathematical content. Ideally, the detailed descriptions in cells resonate with practitioners to inform decisions regarding curriculum programs and the kinds of mathematical experiences they envision for their students. Furthermore, the framework could serve as an impetus for mathematics educators to discuss the optimum combination of the activity/tool pairings, the extent to which tasks should involve ambiguity, and the desired level of ambiguity across a set of tasks. The analysis revealed some homogeneity between programs that may have been the result of analyzing only commercially developed programs. In future analysis, we will include at least one NSF-funded program to possibly draw distinctions between types of curriculum programs.

The framework builds on the notion of non-routine nature of tasks as a mechanism to emphasize their ambiguity and potential for connections. When tasks are ambiguous or offer multiple approaches, they provide opportunities for students to collectively negotiate the meaning of the relationships between approaches and the mathematics that makes them similar or different, which we characterize as dialogic potential. Curriculum programs that are comprised of primarily non-routine tasks are communicating that mathematics is an objective and established body of knowledge that has binary forms of understanding or performance, while programs that have a substantive number of non-routine tasks communicate that knowledge is

collectively determined by the community in which that knowledge is discussed and used. These approaches involve monologic forms of communication (e.g., transmission from one person or group to another) or dialogic forms (e.g., knowledge is created by the community that uses it, within some bounds of convention). Both approaches have their uses; the decisions educators face is what combination of these approaches is ideal or desired.

We interviewed 15 rural K-12 administrators or instructional leaders with responsibilities related to mathematics education in their school or district. We asked these educators about how curriculum programs were adopted in their districts to understand the rationale for selection and the processes by which curriculum programs were selected. We identified five themes: a range of stakeholders were involved in the adoption process; the criteria for adoption included state standards, internal criteria, and external rubrics; the typical length of adoption cycles was three to seven years; there were processes that informed the adoption process; and vendors had a role in the adoption process. We summarize these themes and explain their implications for learning opportunities for middle school students in rural areas.

Keywords: Curriculum, Middle School Education, Policy, Standards

Mathematics curricula exert a considerable influence on learning opportunities for students, given the role they play in teacher lesson planning and subsequently the nature and sequencing of tasks students encounter (Remillard & Heck, 2014). Consequently, the choice of a curriculum program plays an important role in students' mathematical education. Research exploring the impact of the Common Core State Standards for Mathematics (CCSSM) showed how adopted curriculum programs were a stronger influence than the CCSSM on the mathematical activities and discourse observed in middle school classrooms (Choppin et al., 2022).

Rural contexts pose unique challenges to educators relative to urban or suburban areas, given their geographic remoteness, smaller populations, and limited resources (Irvin et al., 2012; Jimerson 2005; Monk 2007). To better understand how these factors impact learning opportunities for students in rural-serving schools, we explored the curriculum adoption process in rural mathematics middle grades to better understand the rationale for choosing which curriculum programs to adopt and the processes by which the programs were chosen.

This study was part of a larger study that is exploring the landscape of rural mathematics education in grades 5 to 9. In Phase One of the study, we surveyed middle grades teachers and instructional leaders. We recruited a subset of the teachers and instructional leaders from the survey to participate in semi-structured interviews that included questions on curriculum adoption processes. In the summer and fall of 2025, we interviewed 15 instructional leaders; these interviews form the basis of the analysis for this proposal to answer the research question: How are mathematics curriculum programs selected in rural contexts?

Background and Framing

Rural Mathematics Education

Rural schools face numerous challenges due to their geographic isolation from other communities and larger urban areas (Saw & Agger, 2021). Teachers in rural mathematics classrooms frequently begin their careers with limited preparation tailored to the specific demands of rural schools and mathematics teachers, more broadly, in rural schools have fewer opportunities to attend content-specific professional development and fewer colleagues with whom to collaborate (Cady & Rearden, 2009; Dille & Røkenes, 2021; Şahin et al., 2024).

Financial challenges mean that some rural schools have reduced access to technology and STEM educational opportunities (Bouck, 2004). This negatively affects the courses available to students (Anderson & Chang, 2011), resulting in rural students having less access to highly credentialed teachers and advanced math courses (Monk 2007; Saw & Agger, 2021).

Mathematics curriculum plays a particularly important role in rural contexts, where schools often serve as central community institutions (Villa & Knutas, 2020). Curriculum can provide coherence, ensure equitable access to high-quality mathematical experiences, and create meaningful connections between mathematics and local community contexts. In rural settings, curriculum becomes a critical structure for supporting teacher capacity, sustaining instructional quality, and promoting long-term educational opportunity for students (Carrete-Marín & Domingo-Peñafiel, 2022; Carrete-Marín et al., 2024).

Curriculum Adoption Processes

Curriculum adoption processes in rural schools face unique challenges due to contextual factors such as a lack of acceptance of reform-based pedagogical practices, and standardized content across school locales (Howley & Howley, 2005). Curriculum adoption cycles can be altered due to large-scale curriculum changes, such as No Child Left Behind (Powell et al., 2009) and the CCSSM (Allensworth et al., 2021). More recently, the focus on high-quality instructional materials (HQIM) is prompting districts to consider curricular changes. These efforts are intended to ensure that all students have access to rigorous curricula and instructional practices; however, the variation in curricular resources, access to professional learning, and implementation methods can lead to inconsistent results (Polikoff, 2012).

Methods

Data were gathered from 15 rural school leaders from Ohio, Virginia, South Dakota, Georgia, Louisiana, Tennessee, Washington, and Kansas. Data were collected through semi-structured interviews that lasted approximately 45 to 60 minutes and were intended to support understanding of the affordances and challenges of mathematics education in rural spaces. Interview data were transcribed, participants were assigned pseudonyms, and the instructional leader interviews were coded at the level of turn by themes, using an inductive coding process (Vears & Gillam, 2022). Using this process on the responses to all interview questions, we generated a list of codes used to sort the interviews into topics, one of which was *curriculum adoption processes*. Given the research question of this paper, we collected all quotes related to *curriculum adoption processes* into a single document and then used a multi-phase process to generate themes (Saldaña, 2013). First, we created low-inference memos for each quote to reduce the text while preserving the main ideas. This supported the second phase, in which we grouped the low-inference memos into *sub-themes* to reflect common ideas expressed in the memos. Third, we grouped these sub-themes into larger *themes*, which we reduced to a parsimonious but comprehensive set that captured the key phenomena evident in the sub-themes.

Results

We identified five themes: (a) a range of stakeholders were involved in the adoption process; (b) the criteria for adoption included state standards, internal criteria, and external rubrics; (b) the typical length of adoption cycles was three to seven years; (d) there were processes that informed the adoption process; and (e) vendors had a role in the adoption process. Below, we report on these themes and then discuss their connections and implications.

Stakeholders Involved in the Adoption Process

Nine of the 15 participants reported that their curriculum adoption committee included a range of stakeholders, including parents, community members, instructional leaders, and teachers. Two specifically mentioned community members and parents as being involved, while another mentioned the need to attend to the community's conservative values. Three of the participants emphasized the role of teachers in the adoption process, stating that teachers were primary decision makers, while eight others mentioned teachers as playing an important role. One participant stated, "if you teach math, you get a seat at the table in determining what's best for your students," while another stated, "we definitely use teacher voices a ton in order to support what purchases we make." Four participants stated they sought School Board approval or informed the School Board of their choice. Typically, the composition of the adoption committees included teachers from each grade level, mathematics specialists, directors of curriculum, and building-level administrators.

Criteria for Adoption

The participants listed three types of criteria used to adopt curricula: (a) rubrics, generated locally or by another entity, and criteria reported by EdReports (EdReports.org, 2026); (b) state standards; and (c) internal criteria that reflected the values or instructional philosophies of the teachers. Four participants reported rubrics to evaluate programs; in three cases, the rubric was internally generated, and in one case, the participant used the Equip Rubric (Achieve, 2013). Three participants reported using EdReports to identify programs, including one who stated: "I usually go to EdReports to see what curricula are scoring where, and then I usually get samples … I usually look at the ones that score all green." Five participants reported using state standards as a criterion to select programs. One participant stated, "I think the constant driving forces are those curricular materials meeting state standards, that's the that's the biggest thing that drives those decisions." Another administrator reported that they only considered curriculum programs that were "fully approved by Virginia for alignment" with their standards. Three participants reported using internal criteria to select programs. One participant reported that differentiation was an emphasis, stating, "We have students because we are a smaller school, of varying backgrounds and varying abilities in one classroom, so making sure that the material is not a sit and get." Another stated, "We want kids to be able to manipulate things, to learn math … So that's a piece that … guides us. What does that look like for this particular company?"

Length of Adoption Cycles

Participants reported three-to-seven-year cycles. The length of the cycles added extra importance to the adoption process. One participant stated, "it's a pretty big investment for us, and we want to make sure that we're going to be happy for five years." Two participants explained that their adoption cycles were aligned with the typical period for revising state standards, with one saying that their cycle was "generally based on when the [state] standards get updated."

Processes that Informed the Adoption Process

The two processes reported by participants included a pilot period in which they tested out programs for one or more years before adopting, and an ongoing evaluation process for their curriculum programs in advance of the next adoption cycle. Five participants reported piloting two to three programs for up to two years before the adoption decision. One participant described the piloting process, "We piloted two programs … and then the pilot teachers met, and we also had some community members that came joined us to score the programs." Three participants

reported evaluating the effectiveness of their current programs between adoptions. One participant reported:

> Throughout the year, we reflect on and say, are we using these? How are we using them? When are we using them? Are they using them daily, things like that? … We start to think, you know, how did these materials prepare our students?

Another participant described ongoing needs analysis, saying that they "look at the data in regard to how our students are performing. So, what have we noticed where we're weak at standard wise? What have we noticed skill wise? Where have we noticed that that we have those gaps?"

The Role of Vendors in the Adoption Process

Two participants stated that their states provided a list of approved vendors that indicated which curriculum programs the district could consider, with one participant stating, "You have to use one of their vendors; they don't care who you choose, but it has to be one that's been vetted through their office." Four participants reported that vendors met with teachers and instructional leaders to present their programs. They reported that they met with multiple vendors in one day, either at an external site or even via Zoom. One participant described how the state educational service agency would put on "textbook fairs" where the staff could "go to one place and see three different curriculum presentations" by vendors. Another participant reported:

> We invite the reps to Zoom with our staff to get to know them. We might have those Zooms all on the same day on an in-service day, so we can compare some things, contrast some things. They kind of take us through their one-hour, one-and-a-half-hour kind of sales pitch.

A third participant reported that, "The [state-approved] vendors … come to each school. Each school has a representative, and these representatives go and have a meeting with the district supervisor and kind of hash out the pros and the cons."

Discussion

Given the unique challenges of education in rural contexts (Irvin et al., 2012; Jimerson 2005; Monk 2007), the five identified themes add to existing literature on mathematics curriculum adoption processes in rural contexts. Results from leaders in eight states show variation in curriculum adoption processes, including piloting programs before adoption, meeting with vendors, and conducting ongoing evaluation of current curriculum programs, all within their rural areas. Based on existing research that mathematics curriculum strongly influences students' learning opportunities (i.e., Remillard & Heck, 2014), the variation in processes reported suggests possible variation in potential learning outcomes for students in rural contexts. Some participants reported some state control over the process, such as creating a list of preferred or vetted vendors that restricted the choices of curriculum programs or requiring that the curriculum programs aligned with the state standards, which speaks to the power of the decisions made at the state level, knowing that adopted curriculum programs are often a stronger influence than state or national level standards (Choppin et al., 2022). In cases where stakeholders were the primary decision-makers, the values of the rural community were considered in the selection process, thereby elevating the contextual needs of those communities. Those selecting materials should be cognizant of the relationship between decision makers and the community needs, and the unique challenges in rural spaces (Howley & Howley, 2005) as the ultimate decision is consequential for student learning opportunity (Remillard & Heck, 2014).

DISTINGUISHING SELF-CONCEPT AND SITUATIONAL INTEREST IN COLLEGE MATHEMATICS: A VALIDITY EVIDENCE STUDY

Abel Sekone
San Diego State University & UC San Diego
asekone4584@sdsu.edu

Regis Komperda
San Diego State University
rkomperda@sdsu.edu

Math self-concept and situational interest represent two central psychological processes that influence achievement-related outcomes, as well as future STEM career choices. Although prior research has developed or used survey instruments to assess these constructs and has documented various sources of validity evidence, the adaptation of such measures to new disciplinary contexts and combining the two constructs requires renewed validation efforts. As part of that process, the main study goal is to gather the following validity evidence for the two scales measuring math self-concept and situational interest in math: test content and internal structure. Results provide empirical support for sources of validity evidence, indicating that the two scales can be used to accurately measure the underlying constructs of math self-concept and situational interest in undergraduate calculus.

Keywords: Calculus, Undergraduate Education, Validity Evidence

Achievement-related outcomes in mathematics are shaped by students' conceptions of their abilities, termed as mathematics self-concept and their interest in the subject (Ding et al., 2024; Geisler et al., 2023; Nazeri, 2016; Niepel et al., 2022; Pietsch et al., 2003; Valentine et al., 2004). Interest, which can be context-based (situational interest) or long-term (individual interest), reflects both the psychological state during engagement and the likelihood of re-engagement with a given content (Hidi & Renninger, 2006). Beyond achievement, self-concept and interest in mathematics influence long-term STEM participation (Ferdinand et al., 2024; Lu et al., 2026; Parker et al., 2014; Zhou & Shirazi, 2025). These constructs frequently manifest concurrently and mutually influence one another in learning environments (Marsh et al., 2005), yet to our knowledge they are often measured separately, and few instruments examine both together in university mathematics contexts. Therefore, in this brief report, we seek to gather validity evidence for measurement models that combine these two psychological processes.

This study investigates the validity of two survey scales measuring math self-concept and situational interest in a face-to-face Calculus I course. Our research question is: What sources of validity evidence support the use of math self-concept and situational interest scales as acceptable instruments for measuring students' perceptions of their mathematics self-concept and their context-based interest in face-to-face Calculus I?

Theoretical Perspective and Prior Research

This study is part of a larger research project examining relationships among classroom climate, math self-concept, and situational interest in college Calculus I and Business Calculus courses. Guided by theories of self-concept and interest development, as well as the *Standards for Educational and Psychological Testing* (thereafter, the *Standards*; American Educational Research Association [AERA] et al., 2014), this analysis examines two sources of validity evidence, including test content and internal structure to determine whether these constructs are empirically distinguishable and accurately measured within this instructional context.

Mathematics self-concept is a well-established construct grounded in the multidimensional, hierarchical model of self-concept (Shavelson et al., 1976) and supported by research

distinguishing its cognitive and affective components (Bong & Clark, 1999; Bong & Skaalvik, 2003; Hammoudi, 2020). Within this framework, math self-concept reflects individuals' perceptions of their mathematical ability and includes an affective dimension (students' feelings about their competence) and a cognitive dimension (students' awareness and evaluation of their mathematical knowledge and skills). These perspectives inform measurement tools such as the Self-Description Questionnaires (e.g., SDQ III; Marsh & O'Neill, 1984; Rubie-Davies & Lee, 2013), PISA math self-concept scales (OECD, 2013; Ding et al., 2024; Ramazan et al., 2023), and cognitive/affective subscales (Hammoudi, 2020).

Situational interest, defined within the four-phase model of interest development, captures context-dependent engagement driven by triggered interest, maintained value, and maintained feeling (Hidi & Renninger, 2006). Linnenbrink-Garcia et al. (2010) drew from this theoretical perspective and developed a classroom-based measure assessing triggered situational interest (TSI) and two components of maintained interest, which are maintained-situational interest feeling (MSIF), and maintained-situational interest value (MSIV).

To ensure accurate score interpretations as recommended by the *Standards* (AERA et al., 2014), the present study focuses on validity evidence based on test content and internal structure. Evidence based on test content can be collected by asking experts to judge the representativeness or appropriateness of the set of items to measure the constructs in the study (Knapp & Mueller, 2010). Statistical techniques such as confirmatory factor analysis (CFA) and invariance testing provide evidence based on internal structure. Consistent with Lewis (2022), measurement invariance testing also supports equitable score interpretation by evaluating whether an instrument functions similarly across participant groups. Prior studies have gathered some of those sources of validity evidence for the math self-concept subscales (cognitive and affective) used here (Ding et al., 2024; Pietsch et al., 2003) and for the situational interest scale (Linnenbrink-Garcia et al., 2010) in either pre-tertiary educational contexts or in different courses. Therefore, combining two subscales that were developed and used in different contexts to form a new math self-concept scale will require gathering sources of validity evidence to support the specific use of the assessment instrument. Similarly, the situational interest scale was developed in domains including undergraduate psychology course, and middle and high school math class; therefore, an adapted version of the scale for use in undergraduate math courses will require collecting sources of validity evidence. The main hypothesis is that combining measures of math self-concept and situational interest in math will result in a scale that demonstrates evidence based on test content and internal structure, including support for equitable score interpretation across participant groups.

Research Methods

Participants

The study included 385 undergraduates, representing 60% of students enrolled across three coordinated Calculus I courses taught by three instructors during Fall 2025 at a research university on the West Coast of the United States. All demographic information was self-reported; the largest racial/ethnic groups were Hispanic/Latinx (29%), White/Caucasian (25%), and Asian (19%). Participants were primarily engineering majors (63%) and identified as men (61%), women (38%), or non-binary/other (1%). Students reported being continuing-generation (67%) or first-generation (32%), with the remaining 1% selecting another category. For invariance testing, gender was analyzed using binary groups (men vs. women) and generational status using first-generation vs. continuing-generation categories. Test-content evidence was obtained from eight mathematics education and educational psychology experts.

Materials and Data Analysis

For this study, math self-concept and situational interest were measured using five-point Likert-scale items (1 = *Strongly disagree* to 5 = *Strongly agree*). The math self-concept scale included cognitive items (CSC, 5 items; taken from PISA 2003/2012; Ding et al., 2024) and affective items (ASC, 3 items; Pietsch et al., 2003). The situational interest (SI) scale, adapted from Linnenbrink-Garcia et al. (2010) by replacing "year" (used in their pre-tertiary contexts) with "semester" for our college setting, was used to assess TSI, MSIF, and MSIV. Demographic information (e.g., gender, first-generation status) was also collected, given evidence of group differences in mathematics experiences (Sax et al., 2015; Snodgrass Rangel et al., 2020).

To collect test content validity evidence the expert interviews were analyzed. This process led to the identification of relevant or irrelevant items for the constructs. To gather internal structure validity evidence, confirmatory factor analyses (CFAs) tested theoretically grounded models (see Figure 1). Analyses were performed in R version 4.3.3 (R Core Team, 2024) using the *lavaan* package (Rosseel, 2012). Item-level missingness was low (0.78%-1.30%), and all indicators demonstrated acceptable distributional characteristics for robust maximum likelihood estimation (MLR; West et al., 1995). Accordingly, CFAs were conducted using MLR estimation with full information likelihood, which is appropriate for five-category Likert items and missing-at-random data (Enders, 2010; Rhemtulla et al., 2012). Because models were estimated using MLR, robust fit indices were reported for all CFA and measurement invariance models (Savalei, 2014). Data-model fit was evaluated for the four CFA models shown in Figure 1 (Models A–D). Fit-index criteria followed common recommendations for MLR estimation: CFI ≥ 0.95 (good) or ≥ 0.90 (acceptable), RMSEA ≤ 0.05 (good) or ≤ 0.08 (acceptable), and SRMR ≤ 0.08 (Hu & Bentler, 1999; Mueller & Hancock, 2019). The likelihood ratio χ^2 values, factor loadings, and factor correlations were also examined. Finally, additional internal structure validity evidence was collected through measurement invariance across gender and college generational status. Invariance testing evaluates whether the survey scales do not function differently across groups. The second-order 2-factor model was evaluated for configural (same factor model across groups), metric (equal loadings), and scalar (equal intercepts) invariance testing. Evidence of non-invariance was evaluated using same fit indices for CFAs, and changes ΔRMSEA > 0.015 (Chen, 2007) and ΔCFI > 0.01 (Cheung & Rensvold, 2002). Additional details regarding data file, participant characteristics, and R analysis code are available at: 10.17605/OSF.IO/W8SDR

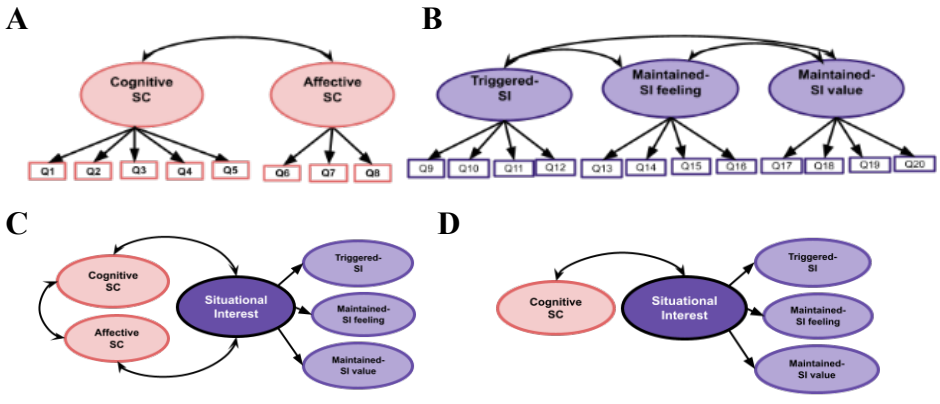

Figure 1: A) Two-factor Math Self-concept (orange), B) Three-factor Math Situational Interest (purple), C) Second-order Three-factor, and D) Second-order Two-factor Models

Results

In the process of gathering test content validity evidence, experts agreed to some extent that items reflected the intended constructs. One expert noted potential overlap between ASC and maintained feeling interest items within SI: "I would also be concerned that the Affective self-concept items will cross-load with the interest items, especially the item with "enjoy" in it".

Table 1 summarizes CFA results. The 2-factor model of math self-concept and three-factor model of situational interest demonstrated acceptable data-model fits. Of interest, the two second-order models also demonstrated good data-model fits; however, because those competing models were non-nested, model comparisons were based on descriptive fit indices rather than chi-square difference testing (Kline, 2023). The second-order model including ASC showed acceptable fit, but the strong correlation between ASC and SI (r = .81) suggested substantial overlap between the constructs. Consequently, the more parsimonious model D (CSC + SI) demonstrated the best overall fit and was retained as the preferred representation of the data.

Table 1: Data-model Fit for CFA Models with MLR Estimation

Model	Scaled χ^2	CFI	RMSEA	SRMR
A) 2-factor Math self-concept	63*	**.957**	.088	**.040**
B) 3-factor Math situational interest	134*	**.974**	**.071**	**.035**
C) Second order 3-factor model of SC & SI	364*	**.956**	**.061**	**.053**
D) Second order 2-factor model of CSC & SI	241*	**.968**	**.058**	**.050**

Note. Acceptable individual data-model fit indices are noted in bold. * p<.001

The results summarized in Table 2 indicate that configural, metric, and scalar invariance were supported across gender and college generational status groups; although the chi-square difference test was significant for the gender metric model, changes in CFI and RMSEA remained below recommended thresholds, indicating comparable item functioning across groups and supporting fair and equitable score interpretation (Cheung & Rensvold, 2002; Lewis, 2022).

Table 2: Invariance Testing by Demographic Groups for Second-order 2-factor Model

Group	Model#	$\chi^2(DF)$	CFI	RMSEA	Model Comp.	$\chi^2\ diff(df)\ p$	ΔCFI	$\Delta RMSEA$
Gender	1.Config	649 (328)	**.943**	**.069**				
	2.Metric	677 (345)	**.941**	**.069**	1&2	**28(17)** .045	**.002**	**<.001**
	3.Scalar	693 (359)	**.941**	**.067**	2&3	**14(14) .419**	**<.001**	**.001**
College generational status	4.Config	601 (328)	**.952**	**.063**				
	5.Metric	620 (345)	**.952**	**.061**	4&5	**16(17) .522**	**<.001**	**.002**
	6.Scalar	637 (359)	**.952**	**.060**	5&6	**16(14) .292**	**<.001**	**.001**

Note. Acceptable individual data-model fit indices are noted in bold. All χ^2 values were statistically significant with p<.001. The sample size for these analyses is N=377.

Discussion and Conclusions

This study gathers validity evidence supporting the use of math self-concept and situational interest scales in Calculus I. Expert review and CFA results indicated overlap between affective self-concept and situational interest, and the more parsimonious model including cognitive self-

concept and situational interest demonstrated slightly better fit than the model including both cognitive and affective self-concept. These findings suggest that cognitive self-concept remains a distinct motivational construct, whereas affective self-concept appears closely aligned with situational interest-related processes. Consequently, self-concept and situational interest may be better understood as related rather than entirely independent motivational constructs in university mathematics. Measurement invariance further supported comparable score interpretation across gender and college generational status groups.

Future work will extend this validation effort by collecting response process and relations-with-other-variables evidence in the larger research project. Future research should also examine consequences of testing by evaluating how use of the scales informs instructional decisions and interventions designed to support students' mathematics self-concept and situational interest.

THE PSYCHOLOGY OF MEANING, PROBLEM SOLVING, AND DRILL: EDWARD THORNDIKE'S MATHEMATICS CURRICULUM 1909–1927

Brandon K. Singleton
Independent Scholar
b.singleton.phd@gmail.com

Edward Lee Thorndike was a founder of educational psychology and the psychology of mathematics learning. Thorndike is understood to have emphasized drill in mathematics and to have neglected meaning and problem solving. However, primary sources reveal that Thorndike paid overt attention to both meaning and problem solving. To clarify Thorndike's views, I systematically studied his mathematics curriculum and its historical context. The results support the interpretation that Thorndike emphasized meaning and problem solving in his mathematics curriculum. He also criticized repetitive drills and designed more meaningful practice. His model of learning, connectionism, provided a scientific explanation of reasoning. These findings raise new questions about how Thorndike influenced early mathematics curriculum design.

Keywords: Curriculum, Learning Theory

Before Edward Lee Thorndike got involved in mathematics curriculum reform from 1909 to 1927, the mathematics curriculum was written primarily by mathematicians and mathematics teachers. They drew upon philosophical ideas about the mind and learning, but they did not have in their possession any rigorous model of the psychology of learning; they did not test their principles through empirical research. Thorndike was the first to develop such a model by studying animal and human behavior in problem situations. Thorndike's attention was devoted equally to matters of psychology and to matters of education, and his psychological model, connectionism, became the basis for educational psychology. Thorndike used his educational psychology to reform the mathematics curriculum. Accordingly, Thorndike is regarded as a founder of educational psychology (Berliner, 1993) as well as of the psychology of mathematics instruction (Resnick & Ford, 1981, pp. 11–13). He was incredibly influential in psychology and education in the United States and abroad.

Although Thorndike thought of himself primarily as a connectionist and criticized the narrowly construed behaviorism of John Watson (Thorndike & Herrick, 1915), mathematics educators usually classify Thorndike as both a connectionist and a behaviorist (Kilpatrick, 1992, pp. 9–10; Steffe, 2017, p. 50, note ii). Because Thorndike's connectionism explained learning via the bonds or habits formed between a situation one meets and the responses one makes to those situations, mathematics educators have had trouble identifying the place for the mind and thinking in his model. When describing Thorndike's mathematics curriculum, mathematics educators have argued that Thorndike emphasized drill at the expense of meaning and problem solving. They have situated this understanding within a narrative of curriculum reform that portrays the early twentieth century as dominated by behaviorism, reductive educational research, and a pedagogy of drill and practice suited for vocations rather than for intellectual development (Cooper-Twamley & Null, 2009; Kilpatrick, 1992; National Council of Teachers of Mathematics, 1970; Resnick & Ford, 1981; Schoenfeld, 2002; Stanic, 1986; Steffe, 2017).

Mathematics educators' existing research on Thorndike unfortunately lacks systematic study of his work. A glance at the table of contents in Thorndike's curriculum planning books reveals that he used the terms *meaning* and *problem solving* alongside *drill* to frame his discussions (Thorndike, 1921, 1922; Thorndike et al., 1923). It is therefore surprising that prior analyses

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

have neglected to discuss Thorndike's views on meaning and problem solving as additional context for his views on drill.

To clarify the nature of Edward Thorndike's mathematics curriculum reforms, I studied Thorndike's mathematics textbooks and handbooks and situated them in his larger career as an educational psychologist and progressive education reformer. Here, I report on one question from that larger study: What attention did Thorndike give in his curriculum to meaning, problem solving, and drill, and how did Thorndike's choices mirror the psychological model of learning—connectionism—that he developed? To answer this question, I studied Thorndike's early career, his books on educational psychology where he spelled out his connectionism, his mathematics textbooks and his handbooks on principles of mathematics curriculum design, and the larger context of progressive education from roughly 1890 to 1930. Although Thorndike's *curriculum vitae* is vast (see Simpson et al., 1926; Woodworth, 1952), I analyzed all of Thorndike's mathematics-related sources and reviewed a generous portion of the books and articles, along with his dissertation, through which he formulated his educational psychology and science of education. My analysis followed norms of historical inquiry, including cross-referencing sources and gathering evidence for and against my interpretations as I cyclically elaborated and refined them. In what follows, I summarize Thorndike's connectionism and his psychology of meaning and problem solving. I then explain how Thorndike approached meaning, problem solving, and drill in the mathematics curriculum.

Connectionism

Before Thorndike became intimately involved with the mathematics curriculum, he spent more than a decade developing an empirical model of learning. In his landmark dissertation study, *Animal Intelligence: An Experimental Study of the Associative Processes in Animals*, and subsequent studies, Thorndike carried out an extensive program of experiments with cats, chicks, dogs, fish, and monkeys (Thorndike, 1898, 1911). Thorndike's purpose was to test hypotheses that would help him infer the degree and nature of reasoning in animals in problem situations such as wooden puzzle boxes with release mechanisms, mazes, item retrieval tasks, and perceptual discriminations. Thorndike's results revealed that it was inappropriate to imagine animal behavior being governed by logical deductions that resembled educated human reasoning. The animals did learn to succeed at their problem tasks, and they did so with increasing speed and competence. However, Thorndike ruled out imitation and logical inference as explanations for animal learning in most cases. The data were more consistent with varied trials and accidental success that gradually conditioned the animal to repeat successful behaviors. His results were devastating to philosophers who explained animal behavior anthropomorphically, and his rigorous methods showed how promising it was to test psychological principles experimentally. Accordingly, Thorndike saw his tests of animal learning as the beginnings of an educational psychology that would give deeper insight into the mysteries of human thought, action, character, and changes to these brought about by experience and education.

Thorndike worked by observing, describing, and measuring learned responses. He varied the experimental conditions to test the factors that best explained learning. He collected a vast corpus of data and interpreted it holistically. Several trends emerged. First, learning was observed in all animals, from the most primitive fish to the most sophisticated monkeys. Second, the number of things learned and the quality of the learning increased as the complexity of the organism's physiology increased. Third, most learning occurred gradually, and changes in behavior usually passed through uneven transitional phases rather than instant tipping points. This meant that most learning in nonhuman animals was through habituation rather than through

ideation or principled reasoning. Fourth, changes to behavioral patterns were caused by the effects of the animal's actions and not by mere repetition of the acts alone. Thorndike recognized that the state of mind, or attitude, or predisposition of the animal was necessary to explain the course of learning; it influenced what the animal did in a given situation and what consequences it found satisfying or annoying. Animals learned to repeat behaviors that brought satisfaction and diminish behaviors that did not. Learning was an active, not a passive, affair, and behaviors were strongly associated with both the situations that evoked them and the consequences that ensued from them in the mind of the animal (Thorndike, 1898, 1911).

After 1911, Thorndike ceased the animal experiments that defined his early career and turned decisively to the problems of human learning, a goal that had motivated his animal experiments in the first place (Thorndike, 1898, p. 2). He brought the insights he had gained from his studies with animals, but he enlarged the principles of learning to encompass the mature forms of thinking and reasoning evident in human behavior and problem solving. In bridging the gap between animal and human learning, Thorndike was careful to point out that human learning is not identical with animal learning (Thorndike, 1898, pp. 86–87), but he also avoided the common tendency among philosophers to disregard animal psychology completely. Thorndike was unsatisfied with speculative explanations of the human mind that appealed to mystical laws of rationality. He therefore started from the principles of animal learning and explored how they operated more fully and with finer sophistication in human learning. He attributed the advantages of humans to their more complex brains and their rich mental life of ideas. He traced out the origins of mental processes such as abstraction and generalization to explain the forms of thinking, reasoning, and problem solving observable in human learning (Thorndike, 1901).

In Thorndike's three-volume series, *Educational Psychology*, he summarized what was known about human nature, human learning, and the possibilities and limits of human abilities (Thorndike, 1913a, 1913b, 1914c). He reported results of experiments by himself and others across a variety of tasks and situations. Although the complete theory is too complex to describe here, a few results are of special interest. Human nature from infancy included instincts for intellectual activity and exploratory play. Perceptual stimulation was interesting, and free activity was interesting, but most interesting of all was connecting actions to their observed consequences. Perception was not a passive experience but was the outcome of learning. Humans perceived similarities and differences based on their prior learning and abstracted new qualities of things by interacting with them. Abstractions compounded on prior abstractions and led to intellectually refined perceptions of qualities and relations. Judgments across classes of experiences led to generalizations. These abilities resulted in highly complex meanings.

Thorndike paid special attention to the relationship between learned habits and problem solving. A leading question for psychologists was how individuals approached novel situations. Did they call upon their prior repertoire of habits, or did they set those habits aside and call upon some higher reasoning faculty? Thorndike was dissatisfied with accounts that invoked a mysterious reasoning faculty but did not explain it. He thought habits had been unfairly discredited. Reasoning was not hindered but enabled by prior habits, in Thorndike's view. Habits ranged from the most thoughtless repetitions under vaguely perceived circumstances to the most insightful discriminations of and judgments about the relevant parts of a situation. When facing a novel problem, individuals responded as best as they could by assimilating the situation or parts of it to meanings from situations they had faced before. They then used their habits from prior learning to get as far as they could toward the goal, using consequences and feedback to adapt their responses where necessary. New combinations and amalgamations of old habits thus led to

new habits. The subtle and adaptive nature of habits explained why they sometimes appeared to go beyond or even counteract existing habits in sophisticated reasoning. Thorndike affirmed, "Successful responses to novel data, association by similarity and purposive behavior are, however, in only apparent opposition to the fundamental laws of associative learning. Really they are beautiful examples of it" (Thorndike, 1913b, p. 46).

Armed with a sophisticated educational psychology that outpaced the informal, speculative accounts of learning that preceded him, Thorndike was prepared to suggest implications to education. He wrote about the fundamentals of human education broadly, and he used empirical research to inform school organization and curriculum planning at the broadest levels (Thorndike, 1906, 1914a, 1924, 1928).

Thorndike's Mathematics Curriculum

Thorndike's first involvement in the mathematics curriculum was in 1909 when he wrote a five-booklet series of supplemental practice problems spanning grades 2 through 5. He began to articulate principles of mathematics learning and pedagogy in about two dozen journal articles for *The Mathematics Teacher*, the *Journal of Educational Psychology*, and other journals between 1910 and 1922. He wrote an arithmetic curriculum for the elementary grades in 1917 and for Jr. High arithmetic and algebra in 1925. He repurposed his algebra material in a book for high school in 1927. In 1921–1923, he published professional handbooks for teachers and curriculum writers that spelled out the underlying principles and considerations that informed his mathematics curriculum design. These handbooks, *The New Methods in Arithmetic*, *The Psychology of Arithmetic* and *The Psychology of Algebra*, were the first of their kind. Never had a psychologist so thoroughly commented on the school mathematics curriculum and been so directly involved with writing it. Thorndike used problem samples from his own books to draw out and explain the underlying theoretical principles of curriculum design. In what ways did Thorndike treat meaning, problem solving, and drill in these mathematics curriculum materials?

Meaning

Thorndike argued that students develop mathematical meanings from "what they *do with*" facts rather than by "what they *are told about* them" (Thorndike et al., 1923, p. 242). Accordingly, Thorndike criticized lessons that began with tedious definitions of unfamiliar concepts followed by application problems. Teachers of those lessons made two errors: they assumed that students could make sense of abstract definitions ahead of experiences with the actual concepts involved, and they posed application problems that students could not profitably engage with until the meanings had already been mastered. Student needs, in Thorndike's view, had been entirely neglected. Thorndike preferred instead to design problems that brought insight into the underlying principles. After students had accumulated sufficient experience with the relevant concepts, the teacher or textbook would provide students with useful terms and definitions. The subtle qualities and relations behind concepts would be learned gradually. Thorndike did not expect students to master a concept at the first learning, no matter how thorough or complete a teacher's explanation or definition was. He observed that students typically began with crude meanings and refined them as they confronted sets of diverse and instructive problems (Thorndike, 1921, pp. 225–229; Thorndike et al., 1923, pp. 240–242).

Thorndike chose problems carefully to ensure students had opportunities to develop useful meanings. A strong arithmetic curriculum was based on a robust meaning of number (Thorndike, 1922, pp. 2–8). Philosophers prior to Thorndike had articulated four meanings that Thorndike drew from. The series meaning, promoted by Daniel E. Phillips, was to know that *one* was the name for the first number, after which came *two*, then *three*, and so on, counting as high as

possible. Phillips thought this meaning arose from the serial and rhythmic experiences of early life, such as breathing, long before cardinality was understood (Phillips, 1897). The collection meaning was to know that a number represented the amount or cardinality of a set. The ratio meaning, promoted ardently by William W. Speer (1897) and James A. McLellan and John Dewey (1895), was to think of number as measurement in a multiplicative relationship with a designated unit, the entity connoting 1. A final meaning came to be known as the relational meaning. Its method, first advanced by Grube in Germany (Seeley, 1888), was to put each number in all possible relations with other numbers through addition, subtraction, multiplication, and division, advancing systematically from each number to the next in instruction. Thorndike's attitude was that each meaning of number was important and that all the meanings should be cultivated in a harmonious and useful way. He criticized pedagogical programs that cultivated number knowledge too narrowly through a single meaning in isolation from the others. He also criticized programs that were unnecessarily formal and systematic, instead emphasizing a diversity of quantitative problems that were sequenced according to natural psychological development in children. For instance, he bemoaned the monotonous and systematic drills on small numbers in the Grube method. He also advised against teaching exclusively from the ratio meaning, despite its merits, because children more instinctively grasped counting at the outset and developed ratio thinking gradually thereafter (Thorndike, 1922, pp. 5–8, 207–208). Thorndike was not branding a proprietary method of instruction in number with a catchy name and a rigid formula; he was instead showing how wise coordination of principles tempered the radical, extreme curriculum programs at the time and led to more balanced growth in number knowledge.

Thorndike likewise articulated the worthwhile algebraic meanings for students to develop. In a traditional algebra course, students were taught simply to solve for the variable in an equation. Thorndike was concerned that this treatment could become too mechanical and constitute mental gymnastics if not accompanied by a relational meaning. He explained, "The understanding of equations as the expression of relations, goes straight to the heart of all applied mathematics, showing the formula and equation as the story of a rule or law which certain events in nature follow or approximate; it introduces the most important idea of mathematics, that of quantitative dependence or functionality" (Thorndike et al., 1923, p. 107). Thorndike made curriculum recommendations to help students reach the latter meaning more effectively. He criticized the routines teachers used that crippled students' ability to think about algebra relationally. He distinguished between *particular equations*, such as those used to solve unknown-value problems, and *general equations*, which expressed general relations among changing quantities. To cultivate understanding of the latter, he had students use relationships such as "Length in feet = (length in inches) ÷ 12", evaluate relationships at many different values of the variables, plot relations on a cartesian graph, trace with chalk how the y-values varied together with the x-values, study proportional, linear, and nonlinear relationships, and interpret multi-variable relationships by reasoning about how changes to one variable influence another (Thorndike et al., 1923, pp. 105–108, 121–131, 252–255).

Problem Solving

Thorndike explained that problem solving was a desirable condition for mathematics learning (Thorndike, 1914b, p. 146). Invoking the authority of John Dewey, Thorndike espoused the view that students be "active seekers" working on problems that satisfied "some real need" rather than being "led along blindfold as it were by the teacher and textbook, not knowing where they are going or why they are going there" (Thorndike, 1922, p. 266). Thorndike wished for students to

work under a problem attitude throughout all the problems and exercises in the curriculum. A problem attitude meant that students took interest in and saw value in the problems they solved, and they used genuine forms of reasoning that resembled the kinds of reasoning they might use in comparable situations in everyday life. Thorndike criticized remote and unrealistic problems, replacing them with more sensible and appealing scenarios. He criticized rigid book organization by chapter and topic such that all problems using a common method were grouped together. After shuffling and regrouping problems more organically, Thorndike hoped to promote greater thought and discrimination in the methods selected (Thorndike, 1922; Thorndike et al., 1923).

Problem solving meant facing new problems and trying to work them out before being given a technique or method. Thorndike maintained that "other things being equal, it is more educative to solve a problem as an original" and that "pupils who are able to solve a certain type of problem as an original should certainly be excused from training in a routine method of solving it" (Thorndike et al., 1923, pp. 150–151). Even if students did not arrive at the solution independently, their preliminary efforts were worthwhile to their total learning. Thus, Thorndike tended to introduce the standard arithmetic algorithms by first allowing students an opportunity to solve the problem with a simpler method they already knew. They could use their results to verify that the new algorithm worked as expected. Although Thorndike did not require students to derive and justify standard algorithms from first principles, he took care to ensure that students understood and appreciated the problem at hand and recognized the computational service done for them by the algorithm. He had students verify algorithms using their prior methods and number sense so that they did not put their trust blindly in an outside authority. Where possible, Thorndike crafted additional problems that helped students see into the whys behind the standard algorithms (Thorndike, 1922, pp. 60–74, 81–83, 115–117, 266–277). Furthermore, he chose to "give no rules for rules' sake" (Thorndike, 1921, p. 234). If students solved problems effectively without formal rules and procedures, there was no need for the rules, Thorndike insisted.

Thorndike used an inductive teaching approach rather than a deductive teaching approach. The inductive approach lessened the importance of teacher explanations and increased the importance of problems designed to teach students through their own efforts. Students were meant to gain insight into quantitative principles by working directly with problems that gave rise to those principles. The teacher was to act as a guide, using questions to help the students express their reasoning and make corrections until the problem was solved. Deductive explanations and proofs were positioned near the end, rather than the beginning, of the teaching sequence, helping students acquire the vocabulary to talk about the things they'd learned and to generalize the patterns and principles they observed earlier (Thorndike, 1906, pp. 147–164; 1921, pp. 37–49, 147; 1922, pp. 74, 115–117).

To get the most value from problem solving, Thorndike believed that mathematics teachers needed to be more intentional and selective with the problems given. Before Thorndike had carried out the experiments that informed his connectionist psychology, mathematics teachers subscribed to a view known as faculty psychology. They believed that training in mathematics strengthened a few core mental faculties, such as perception, judgment, and reasoning. The outcome of such training was mental discipline, and mathematics, along with Latin and Greek, was thought to be superior at cultivating mental discipline. When carried to the extreme, this view justified mathematics teachers in giving indiscriminate exercises. Meaningless and computationally tedious problems were perpetuated by the mere force of tradition. As a response to these conditions, Thorndike carried out experiments that refuted faculty psychology. Thorndike did not discredit transfer, but he sobered expectations regarding its extent and

pressured teachers and curriculum authors to plan programs of study that were useful and worth learning about. Thorndike called for more attention to useful fundamentals and less emphasis on tedious, elaborate, specialized computations and procedures with large numbers and complex algebraic polynomials. Thorndike was critical of word problems that he viewed as bogus or contrived. Students would lose respect for arithmetic and algebra if they were fed a steady diet of such problems, Thorndike believed. Thorndike discussed the uses of intellectual or puzzle problems and problems that required students to reason about algebraic relationships through nonroutine solution methods. Finally, Thorndike pioneered tests that were intended to measure students' general ability to reason and solve problems so that the disciplinary worth of mathematics courses and other courses could be better defined, observed, and measured (Thorndike, 1921, 1922; Thorndike et al., 1923).

Drill

The term *drill* was not new when Thorndike used it to describe mathematics teaching. It was a widely circulated term with multiple meanings. As Joseph Mayer Rice's sweeping surveys of American classrooms between 1892 and 1893 showed, repetitive drill and recitation was commonplace (Cremin, 1961, p. 5; Cuban, 1984). However, some pedagogies framed drill for more instructive purposes. For instance, the mathematics professors and school principals who penned the mathematics recommendations in the 1893 report by the Committee of Ten used the term *drill* for targeted or intentional practice aimed at cultivating particular ideas and abilities ("Report of the Committee on Secondary School Studies," 1893, pp. 111–112).

Thorndike criticized rote drill and devoted a lot of effort to clarifying the nature of effective drill in the mathematics curriculum. He suggested that drill be more meaningful, more authentic, more intellectually varied, less repetitive, and less mindless. Thorndike's typical attitude was expressed well in the following quotation.

> Another means of stimulating the essential interest in quantitative thinking itself is the arrangement of the work so that real arithmetical thinking is encouraged more than mere imitation and assiduity. This means the avoidance of long series of applied problems all of one type to be solved in the same way, the avoidance of miscellaneous series and review series which are almost verbatim repetitions of past problems, and in general the avoidance of excessive repetition of any one problem-situation. Stimulation to real arithmetical thinking is weak when a whole day's problem work requires no choice of methods, or when a review simply repeats without any step of organization or progress, or when a pupil meets a situation . . . for the five-hundredth time. (Thorndike, 1922, p. 225)

Thorndike insisted that the quality, not the quantity, of practice was the thing to improve (Thorndike et al., 1923, p. 334). He used variety to stimulate thinking. He devised questions that allowed students the freedom to think of examples, to prove things, and to choose methods strategically based on the unique affordances of problems. Variety did not mean randomness without purpose. Thorndike chose numbers and question formats intentionally to create the experiences that best suited his aims. Special exercises involving patterns and relationships were used to help students discover principles through counting, relating operations to one another, working with place value and multi-digit algorithms, extending whole-number knowledge to fractions and decimals, and so on. He gave students enough practice to make their habits sure and reliable, but he did not want those habits to become automatic in the sense of unconscious or without awareness. He measured the distributions of problems in common textbooks and provided loose rules of thumb to make learning more complete and economical.

Thorndike's criticisms of repetitive drills were sensible given that his connectionism explained learning through the effects of one's acts in light of a purpose rather than through the mere repetition of those acts. Because other psychologists had supposed repetition explained learning, Thorndike carried out experiments to test whether repetition alone brought about changes to behavior patterns over time. These tests gave strong evidence to the contrary. "So far as I can now see, the repetition of a situation in and of itself has no selective power," Thorndike concluded (Thorndike, 1931, p. 14).

Thorndike believed that units of learning, which he frequently referred to as bonds, were more effective when they were interrelated and organized into a total intellectual system. He therefore advised that programs of practice be organized to cultivate insight into relationships and principles. He did not wish for number facts to be learned in isolation and remembered independently. Rather, he hoped for prior knowledge to facilitate the acquisition of new knowledge (Thorndike, 1922, pp. 137–139).

Implications and Future Questions

The foregoing evidence suggests that Thorndike's views on meaning, problem solving, and drill in the mathematics curriculum were more sophisticated than has been supposed. Likewise, connectionism was a more fruitful basis for reforming the mathematics curriculum than has been supposed. Thorndike explained thinking, perception, abstraction, generalization, and reasoning about novel problem situations through his connectionism. He used these insights to propose a mathematics pedagogy that, although imperfect, thoroughly critiqued traditional mathematics curriculum materials and placed enormous pressure for sweeping improvements. Thorndike can profitably be understood as a reformer who centered the student rather than the teacher in mathematics curriculum design and who ambitiously attempted to make mathematics more interesting, useful, and rewarding to learn. The fact that so many of Thorndike's mathematics curriculum principles and psychological insights fell into obscurity and went unnoticed in our field for the better part of a century is worthy of contemplation. To advance as a field, it is important to understand our history and disciplinary foundations, account for the forces that influence curriculum reform, and assess the progress and setbacks that we have attained by our efforts. Thorndike's case suggests that there is unrecognized work to be done along these lines.

The findings of this study raise new questions about Thorndike's influence on the mathematics curriculum between 1909–1927 and thereafter. What did students and critics have to say about Thorndike's mathematics curriculum reforms? How did Thorndike's connectionism dictate the terms of the conversation about mathematics teaching and learning? What alternatives to connectionism arose, and why? How did Thorndike's larger program of educational research shape the role of mathematics in curriculum policymaking and school organization? Thorndike's case is remarkable considering how central he was during the modernization of American schooling and how much his reputation suffered during later periods of reform. There is much to learn about the formation of mathematics education as a community during the progressive years from about 1890 to 1950.

Keywords: Data Analysis and Statistics, Curriculum, Undergraduate Education

The Guidelines for Assessment and Instruction in Statistics Education (GAISE) college reports (Aliaga et al., 2005; Carver et al., 2016) call for the use of real, contextualized data, active learning strategies, and appropriate technology in introductory statistics courses. Many undergraduate students leave introductory statistics harboring misconceptions (Garfield, 2002). Undergraduates rely on the textbook as their main resource, using it for content review, worked examples, and practice problems (Zieffler et al., 2013). Despite the role of texts in shaping the enacted curriculum, they remain an under-examined resource; most studies to date have used the 2005 GAISE recommendations as an analytic instrument (e.g., Dunn et al., 2017). This study evaluated the alignment of descriptive statistics chapters of three introductory statistics textbooks (henceforth referred to as text/texts) with selected 2016 GAISE recommendations.

This content analysis study examined end-of-chapter tasks in the descriptive statistics chapters of three texts that claim GAISE alignment (De Veaux et al., 2022; Moore et al., 2021; Triola, 2021). A single task (including all subparts) was the unit of analysis. We focused on the GAISE (2016) principles that can be meaningfully assessed in a text: *investigative statistical thinking (G1)*, *integrating real data with context and purpose (G3)*, and *using technology to explore and analyze data (G5)*. Tasks were coded for *G1* and *G3* on a 0-2 ordinal scale indicating *minimal*, *partial*, and *robust* alignment. For *G5*, we only coded tasks where technology use was either explicitly required or clearly implied. We reached 89.9% intercoder reliability before coding all data and discussing discrepancies.

Table 1 summarizes the findings (M, P, and R are minimal, partial, and robust). Across all three texts, procedural tasks substantially outnumbered tasks that promoted investigative statistical thinking, and technology was required relatively infrequently. Triola (2021) emphasizes procedural fluency and minimal integration of technology; De Veaux et al. (2022) offer a more balanced approach with opportunities for robust reasoning; while Moore et al. (2021) prioritize engagement with real data and offer moderate engagement with technology.

Table 1: GAISE Recommendation Alignment by Text

GAISE	Triola (2021)				De Veaux et al. (2022)				Moore et al. (2021)			
Recommendation	N	M	P	R	N	M	P	R	N	M	P	R
G1	202	68%	26%	6%	204	48%	38%	15%	83	65%	25%	10%
G3	202	35%	63%	2%	204	29%	66%	5%	83	14%	82%	4%
G5	37	56%	41%	4%	34	50%	29%	21%	33	24%	61%	15%

Our findings suggest that publisher claims of GAISE alignment do not necessarily translate into robust opportunities for students to engage in investigative statistical thinking, meaningful use of technology, or critical engagement with real data.

POSITIONING MATHEMATICS AS DECISION MAKING IN MIDDLE SCHOOL ENGINEERING DESIGN STEM LAB

Keywords: Instructional Activities and Practices, Integrated STEM / STEAM, Problem-Based Learning

Mathematics instruction was embedded within a Project-Based Learning (PBL) unit integrating the Engineering Design Process (EDP) to strengthen meaningful connections between mathematics and engineering. Rather than treating mathematics as a separate subject, students engaged in mathematical reasoning as they defined problems, generated solutions, tested prototypes, and redesigned based on evidence. Within iterative EDP cycles, students used measurement, proportional reasoning, spatial reasoning, scaling, and data analysis to evaluate constraints and optimize designs, supporting mathematical modeling and evidence-based argumentation (National Council of Teachers of Mathematics [NCTM], 2014; Schoenfeld, 2014).

This study investigated how positioning mathematics as a decision-making tool within iterative PBL/EDP cycles influenced students' mathematical reasoning in a middle school STEM laboratory. Using a mixed-methods action research design (Creswell & Plano Clark, 2018), data were collected over two academic years from approximately 120–150 seventh- and eighth-grade students enrolled in a STEM/STEAM elective at a Title I middle school. Quantitative and qualitative data were collected concurrently, analyzed separately, and integrated during interpretation.

Analysis revealed four key episodes illustrating shifts in students' mathematical reasoning. First, *Constraint-Driven Quantification* emerged as students moved from intuitive judgments (e.g., "this looks stronger") to using measurements and proportional reasoning when required to meet design constraints such as load limits or filtration rates. Second, *Iteration and Covariational Reasoning* developed across redesign cycles as students coordinated changes in design variables with changes in performance outcomes. Rather than attributing results to chance, students analyzed relationships between quantities, such as how base width or material thickness affected load capacity or flow rate, demonstrating emerging covariational reasoning (Thompson & Carlson, 2017).

Third, *Representational Reasoning and Modeling* evolved as students progressed from informal sketches to labeled diagrams, tables, and graphs. These representations enabled students to track relationships among quantities, interpret results, refine designs, and communicate evidence-based mathematical arguments (Lesh & Doerr, 2003). Finally, *Reasoning as Participation* reflected shifts in students' identities as mathematical thinkers. Student reflections suggested that mathematics became a shared resource for explaining and predicting outcomes rather than a teacher-imposed requirement. Statements such as "the numbers show what works" indicated increasing ownership of quantitative reasoning.

Findings suggest that engineering design constraints create authentic modeling demands that make mathematical reasoning necessary and meaningful. By positioning mathematics as a tool for decision making, PBL/EDP environments can support students' development of quantitative, covariational, and representational reasoning while fostering productive mathematical identities.

ADAPTING A NOTICING OF ARGUMENTATION FRAMEWORK FOR ELEMENTARY INTEGRATED STEM CONTEXTS

Uyiosa O. Ugiagbe

Keywords: Professional Teacher Noticing, Mathematical Argumentation, Integrated STEM, Elementary Mathematics

Mathematical argumentation is central to meaningful mathematics learning (Stylianides, 2007), and what teachers attend to when selecting and planning tasks shapes whether and how argumentation is supported in their classrooms (Ayalon & Hershkowitz, 2018). Yet research on noticing of argumentation has focused almost exclusively on secondary mathematics. Ayalon (2024) developed a model specifying what teachers should notice when students construct arguments, interpret the factors shaping argumentation, and respond with instructional alternatives, but it was built for secondary teachers analyzing written student work from classrooms other than their own. No existing framework addresses how elementary teachers notice mathematical argumentation in integrated STEM environments, where coding artifacts, robot behaviors, and digital representations create new sites for reasoning (Shumway et al., 2023). This poster presents a framework adapted for this context.

We adapted Ayalon's (2024) model to account for three contextual shifts: (a) elementary students' argumentation tends to be intuitive and empirical rather than formal and deductive (Knox & Kontorovich, 2023); (b) video-stimulated recall interviews (Lyle, 2003) capture teachers narrating perceptions of their own instruction rather than producing written analyses of others' classrooms; and (c) integrated STEM environments introduce technology-mediated evidence that may not be recognized as mathematical justification by teachers who view mathematics and coding as separate activities. Drawing on Louie et al.'s (2021) argument that framing precedes and shapes other forms of noticing, we added framing as a fourth component. Pilot data from a third-grade teacher implementing a coding-infused area measurement unit motivated this addition; her framing of student engagement in mathematics and coding as sequential rather than integrated organized her entire noticing pattern. Table 1 presents an overview of the revised framework. We used binary assessment designations (present/absent) to replace Ayalon's numbered levels across all components, with richer narrative variation. Interpreting sub-factors were streamlined from 19 to 10 through principled merging of overlapping constructs and addition of sub-factors grounded in pilot evidence.

Table 1: Framework Overview

Component	Focus	Dimensions/Factors
Framing	How the teacher conceptualizes the integrated activity and the role of mathematics within it	3 Dimensions
Attending	What the teacher notices about students' mathematical reasoning	2 dimensions; 7 sub-dimensions
Interpreting	How the teacher explains what shaped the reasoning observed	4 factors, 10 sub-factors
Responding	What instructional alternatives the teacher proposes	Quality and target category analysis

SEQUENCING MATHEMATICAL CONTENT OF THE INDIVIDUAL

Stephanie T. Varga
University of Alberta
svarga@ualberta.ca

Keywords: Curriculum, Cognition, Instructional Activities and Practices

Curriculum content and its sequencing, referred to as scope-and-sequence herein, often falls short of accounting for how learners "make sense" (Maker; 1986; Coker et al., 2023; Graves, 2023; Segedinac et al., 2018). This poster presents a method for the learner to construct their own scope-and-sequence of mathematical content. Sensemaking of the individual is accounted for, herein, by visually sequencing the subsequent problems posed by the learner on their way to solving an initial problem. I adopt the practice of Barabé (2023) who diagrammatically shows the subsequent problems posed by a collective of learners around a routine mathematics task. I apply Barabé's diagrammatic technique to the sensemaking of an individual learner to answer the question: *How might the scope-and-sequence of mathematics curriculum account for sensemaking of the individual learner?*

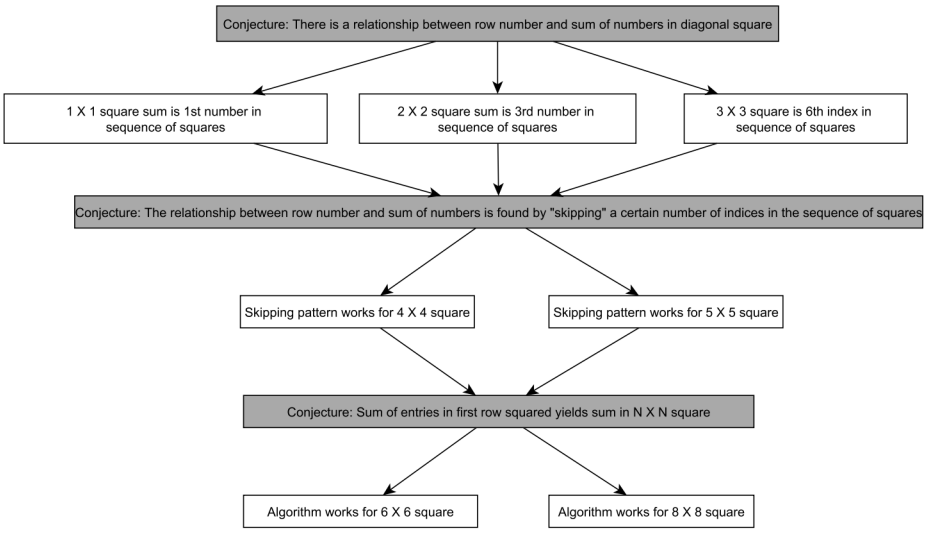

Figure 1 : Diagram Showing Mathematical Sensemaking of a Student (Cifarelli & Cai, 2005)

This poster presentation follows the paradigm of *enactivism* where cognition is considered skillful know-how (Thompson, 2007). This view differs from predominant theories of cognition that are representational, looking at cognition as knowing-what (Thompson, 2007). Enactivists consider *sensemaking* as evaluation undergone by an individual when in a situation unfamiliar to them (Thompson, 2022). I apply here Barabé's diagrammatic technique to excerpts from the transcript of Cifarelli and Cai (2005). The transcript is of a mathematics graduate student, Sarah, who talks-aloud as she solves a problem she has posed. I have analyzed and visualized the precedence relationships between mathematical problems posed by Sarah (Figure 1). This poster describes how the result is a scope-and-sequence that accounts for her sensemaking and how the described method lends itself to future research of mathematical sensemaking.

While researchers continue to advocate for the use of concrete manipulatives to support students in understanding a range of mathematical topics, limited research, especially at the secondary level, has illustrated exactly how such tools enhance learning in the classroom. To fill this gap, we investigated how high school students leveraged algebra tiles to explore quadratic factoring after a week-long unit based on their use. Analysis resulted in a framework of ways students employ algebra tiles to overcome challenges associated with fluency and cognitive load, and ultimately reason more flexibly about factoring. The role of manipulatives and productive struggle is discussed.

Keywords: Mathematical Representations, Algebra and Algebraic Thinking, High School Education

Introduction

Manipulatives have long been used as a tool in supporting students to learn and explore mathematical topics. Cognitively Guided Instruction classrooms have shown that young students are capable of insightful thinking as they use blocks to learn to count and model mathematical problems involving a range of operations (Carpenter, et al., 2014). Manipulatives support mathematical learning by anchoring abstract reasoning in physical interaction as well as providing immediate feedback when exploring new ideas. Students can visualize, review, and correct their steps, enhancing reflection and error detection (Tran et al., 2017). Moreover, the bodily movements and gestures associated with manipulatives provide opportunities to practice mathematical ideas during interaction with concrete or digital objects (Bakker & Van der Kolk, 2019).

While a considerable body of research has explored the use of manipulatives in mathematics classrooms, much of the work has concentrated on assessing performance, comparing outcomes with their use relative to traditional symbol-based methods. Results of such studies have had mixed conclusions (Carbonneau et al., 2013), indicating that the use of concrete objects does not guarantee deeper understanding and can even hinder students' mathematical learning. No doubt the pedagogy associated with how students interact with these tools shapes what they take away from their use. For example, teachers might fail to help students bridge the mathematical meaning between the physical and symbolic representations and instead treat manipulatives as trivial, leading to an instrumental understanding of rote-based procedures (Sarama & Clements, 2016).

In addition to emphasizing comparative outcomes, most research around manipulatives has focused on younger students as they grapple with early operations. As such, there is a critical need to explore how learners, especially those in middle and high school, use such tools to leverage their preexisting abilities, build internal representations, and develop problem-solving strategies, an area where empirical qualitative studies are scarce. The goal of this study is to fill this gap. Specifically, we aim to answer the research question: *In what ways do students use algebra tiles to support their ability to factor quadratics?*

Literature Review

Embodied Learning and Representations

While results of empirical studies involving manipulatives have been mixed, researchers have detailed various theoretical arguments for their use. Theories of embedded and embodied cognition suggest that knowledge transfer requires physical actions to internalize abstract concepts (Pouw et al., 2014). In fact, neuroscience has found that learners continue to use the somatosensory part of the brain which serves to represent physical objects, even when they cease to use their fingers in calculations (Boaler et al., 2016). Such results highlight the important role of embodied learning. Additionally, learning is enhanced by experiencing ideas through multiple modalities. In particular, the abstract nature of mathematics means students only have access to concepts through different representations (National Council of Teachers of Mathematics [NCTM], 2014). As such, a deeper understanding is achieved by engaging with topics through different representations. Han and Black (2011) found that physical simulations with concrete objects form multimodal representations, helping students understand concepts more quickly and transfer knowledge to applications, providing empirical evidence of their benefit.

Manipulative Structure

The nature of manipulatives can also influence learning and engagement. Martin and Schwartz (2005) found that non-descript (bland) manipulatives, such as blocks, foster better transfer of fractions than pre-structured (perceptually rich) materials with a narrow interpretation, such as pie wedges. Although perceptually rich manipulatives may increase interest and activate prior knowledge, surface details can distract from key mathematical concepts and do not necessarily improve performance (Kaminski, et al., 2009). Notably, Carbonneau et al. (2020) demonstrated that bland manipulatives were not only more effective than perceptually rich manipulatives in supporting conceptual understanding, but also contributed to other attributes. They showed that bland manipulatives promoted greater academic perseverance by increasing students' likelihood of trying multiple strategies and persisting longer in problem solving.

Cognitive Offloading

When tasks are too complicated or perceived too complicated for working memory, humans look for ways to use the environment to overcome limits with short term memory, what is referred to as cognitive offloading. From this perspective, another affordance of manipulatives is their ability to help students offload cognitive demand to support the coordination of various problem-solving processes. Manipulatives act as an external cognitive support, scaffolding working memory, and organizing thought processes. For example, when problems require multiple tasks, students can offload different steps of the process to prevent the overload of multiple ideas, helping them to organize tasks and solve problems more accurately and efficiently. According to Risko and Gilbert (2016), the choice to offload can be intentional, using tools, or subconscious through gesturing. Various studies have shown that hand gestures and body movements unconsciously serve to reduce cognitive demands (Goldin-Meadow et al., 2001; Novack et al., 2014; Tran et al., 2017). However, while manipulatives can support learning by lowering cognitive demand and organizing thought, over-reliance on offloading can hinder internalization and metacognitive development (Martin & Schwarz, 2005; Risko & Gilbert, 2016). Therefore, instruction with manipulatives should guide students to gradually internalize mathematical processes beyond manipulatives by fostering sensorimotor interactions that are

mathematically meaningful, rather than relying solely on their physical concreteness (Pouw et al., 2014; Sarama & Clements, 2016).

Factoring with Algebra Tiles

Factoring is the process of transforming an algebraic expression from an additive structure to a multiplicative structure. However, learning to meaningfully factor an expression can be challenging. In most cases, the process cannot be determined directly but requires carrying out the distributive property and identifying patterns to undo this process, a method often referred to as guess and check. While teachers often tell students these number combinations, algebra tiles can be used to explore and develop fluency with such patterns. Since the multiplicative form consists of two expressions multiplied together, they can be interpreted as the dimensions of a rectangle with the resulting product the area (Caglayan, 2013; Lischka & Stephens, 2020). Hence, the goal when utilizing algebra tiles is to arrange the additive pieces into such a rectangle.

For example, the expression $x^2 + 11x + 24$ in additive form can be modeled by algebra tiles, consisting of a single (x by x) tile (or square), 11 (x by 1) tiles (or planks) and 24 (1 by 1) tiles (or blocks) (See Figure 1). To form a rectangle, we start with the square in the top left. We then either distribute the 11 planks on adjacent sides of the square in such a way that the rectangle remaining can be filled in with the 24 blocks or create different rectangles out of the 24 blocks so that the sides align with/add up to the 11 planks. This latter approach is what is typically provided to students when they are told to find two numbers that multiply to 24 and add to 11.

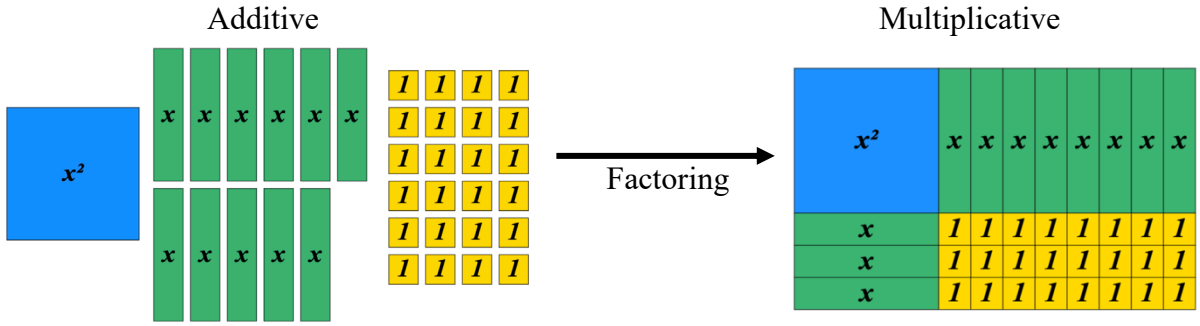

Figure 1: Algebra Tiles Representing the Factoring Process of Transforming the Additive Structure of $x^2 + 11x + 24$ to the Multiplicative Structure of $(x + 3)(x + 8)$

Research on the use of algebra tiles in classrooms is limited. However, results in the few examples indicate subtle, yet positive results associated with their use. For example, in a clinical study, while Carbonneau et al. (2020) found no difference in undergraduate students' ability to complete the square when instruction involved algebra tiles compared to symbolic approaches, algebra tiles did lead to students persevering much more, as they attempted to redo problems almost twice as frequently when they experienced difficulty. In a classroom context, Altizer (1977) found no statistical significance in the scores of pre-algebra students when factoring with or without the use of tiles during instruction, but did not that manipulative students demonstrated longer retention, presumably as a result of visualizing tile-based actions. While most students in both groups struggled to connect factorization as the inverse of multiplication, interview results indicated some manipulative students developed this understanding through imagery built from the physical interactions with the tiles.

Methods

Context

This study took place in a predominantly White (73.7%), rural US high school in the Southeast, with poverty rates equivalent to that of the state. Data collection followed three days of 90-minute instruction, led by the first author, where students were introduced to factoring quadratics using algebra tiles to explore associated patterns. In an effort to capture a range of thinking, two 9th grade Algebra I classrooms, one Regular and one Honors, were chosen. On day 1 (90 minute instruction), students were shown how base 10 blocks could model whole number multiplication using an area model which was then extended to binomial multiplication using algebra tiles. On the second day, students worked in groups, investigating how to factor monic quadratics $x^2 + bx + c$ using the tiles with the goal of generalizing the pattern of finding the combination of numbers adding to term b and multiplying to term c. Instruction was exploratory in nature and organized around group work with students asked to verbalize and discuss their ways of thinking.

Data Collection

To explore the different ways students used the algebra tiles when factoring, on the last day of instruction, nine students (six enrolled in Honors and three in Regular) participated in 30-minute, individual semi-structured interviews (Ginsburg, 1997) which were videotaped. The sample included five boys and four girls, with a racial composition that mirrored that of the school and two classes: six White, two Hispanic, and one Black student. The students were asked to factor two different problems: $x^2 + 12x + 20$ (factorable) and $x^2 + 10x + 20$ (nonfactorable) using the method of their choice and then $x^2 + 11x + 30$ specifically without tiles. Any time students asserted a quadratic was not factorable, they were asked to explain their rationale.

Data Analysis

To systematically examine the solution methods and reasoning afforded by algebra tiles, we began by identifying the different approaches students used as they explored factors and organized these data into addition- and multiplication-related methods. This revealed three cognitive challenges associated with factoring. Documenting these challenges helped us understand how and why students invoked these different resources, exposing nuances in students' reasoning. We then returned to the data and coded each student strategy according to the tools they used and how they used them to navigate these challenges. Using a constant comparison method (Strauss & Corbin, 1994), we looked across different students to identify both similarities and differences in their approaches. This method allowed us to construct a broader framework consisting of three distinct categories of approaches, characterizing the full range of ways students leveraged resources to make progress. In addition, to quantify the degree to which algebra tiles supported perseverance, similar to Carbonneau (2020), we recorded how many trials per question each student attempted to find the factors or determine it was not factorable as well as the average amount of time students engaged with each problem.

Results

Two interconnected findings resulted from this study. The first is the notable challenge factoring monic quadratics presented students and the second is the variety of ways students leveraged algebra tiles to overcome these challenges. Below we outline three cognitive hurdles involved in the factoring process that emerged and then describe the different strategies algebra tiles afforded students in reasoning through these different components.

Challenges Associated with Factoring

Factoring a monic quadratic, $x^2 + bx + c$, requires finding a number pair that adds to b and multiplies to c. One surprising result of this study was how demanding this task was for students. Analysis of student solutions revealed three different cognitive elements involved in this process: 1) fluency with addition and multiplication, 2) coordination of these two operations, and 3) a structured system of exploration/testing. While decomposing factoring into these various subcomponents serves predominantly to illuminate the different resources students brought to bear as each strategy students used was linked to one or more of these challenges, these details also provide insight into the challenges of factoring.

Fluency with addition and multiplication. Students must be sufficiently fluent with addition and multiplication to find two numbers that either add to b or multiply to c. Such an understanding goes beyond carrying out these operations. Direct calculations on two numbers provided can be supported with counting methods as the exact parameters are known. Usually, teachers tell students to start with factors of c, since there are fewer and therefore more efficient than finding two numbers that add to b. However, this approach is quite challenging as it requires students to simply "know their multiplication facts." Blocks can support this process as students can move them around to check which combinations create rectangles, but such a resource is not available in most classrooms.

Coordination of two operations. Students also need to coordinate the multiplication and addition of different number pairs, simultaneously identifying a factor pair and checking its sum or finding an additive pair and checking its product. Often students are asked to do this mentally, which can be quite taxing, especially for those who need the support of counting methods. To ease the cognitive demand, students will write down factor pairs so they can then devote their resources to adding them.

Structured system of exploration/testing. Finally, students need an overall method of keeping track of combinations they have checked and determining the next number pair to examine. Without a structured system, they can check certain combinations but are unable to determine if they have exhausted all possibilities. To overcome this challenge, students are often taught to list all possible factor pairs.

Factoring Strategies Employed with Algebra Tiles

While factoring proved to be quite challenging for almost every student interviewed, all of the participants were able to use the algebra tiles differently to enhance their reasoning in ways that helped address each of the identified cognitive hurdles. The sheer diversity of strategies employed highlight the benefits of such a tool. Depending on the arithmetic fluency students possessed, some relied heavily on the tiles, while others chose more numerical methods. Through our analysis, we identified three categories of approaches, with the first category consisting of three sub-categories (see Table 1). The first group, Tile-Dependents, were characterized by their heavy reliance on algebra tiles. All five students in this category modeled every possibility they explored with tiles, some even recreating the blocks on paper when asked to factor without the tiles. The subcategories emerged as students used separate methods to structure their exploration and keep track of different additive combinations. The second category, Numerical, consisted of two students who relied consistently on symbolic approaches, carrying out and coordinating the addition and multiplication operations mentally. The two students in the third category, Flexible, employed a range of resources, depending on the nature of the problem. While they both clearly possessed the ability to use numerical approaches, at times they leveraged the tiles depending on the nature and challenge of the problem.

Table 1: Strategies to Factoring

Categories (Students)		Description	Average Time	Average Attempts
Tile-Dependent	Unstructured exploration without verification (2)	Errors stem from limited exploration; No verification of errors	1:43	2.6
	Unstructured exploration with verification (1)	Limited structure to exploration; use of alternative resources to check work	3:10	3.5
	Algorithmic exploration (2)	Use algorithm to structure-offload exploration	3:28	6.2
Numerical	(2)	Prioritize mental calculations	1:08	2.4
Flexible	(2)	Leverage a variety of resources	1:12	2.8

Note. Each sub-category in Tile-Dependent group consisted of 1 student from a regular algebra class, while the remaining students are from the honors class.

Tile Dependent

Students in this category relied heavily on the tiles, using them to essentially carry out the operation of addition by counting out the number of planks to match the linear coefficient b and then arranging them to find different additive combinations. Highlighting the degree to which they had offloaded the calculations onto the tiles, they repeatedly needed to count the number of planks distributed into each group as they explored different combinations. However, offloading addition onto the tiles supported them in overcoming challenges with *fluency* and lowered the cognitive demand associated with *coordinati*on, as it allowed them to focus only on multiplication. Nonetheless, they still used different resources to carry out multiplication, as two students were able to calculate the product mentally while the other three leveraged the tiles in different ways. Some used the arranged planks to scaffold skip counting, while others did not carry out multiplication, but tested combinations by placing the unit tiles out or assessing their viability by estimating the spatial area. The necessity of the tools became even more apparent when students were asked to factor without the tiles. Several used their fingers to find additive pairs; others continued to multiply by skip counting, and some recreated and manipulated images of the tiles on paper. As such, while students in the first group were quite reliant on the tiles, they clearly gained critical benefits from their use, leveraging them to explore and make connections on their own, despite lacking strong computational skills.

Unstructured exploration, without verification. The first sub-category included students who lacked a structured exploration strategy, resulting in inconsistent success. They were not exhaustive in their search for factors and struggled to keep track of their work. For example, both students mistakenly determined that $x^2 + 12x + 20$ was not factorable after trying three combinations. Moreover, when errors did emerge, they failed to use alternative approaches to check their work. Both made errors attempting to factor $x^2 + 10x + 20$, one with the tiles and one with calculations, resulting in incorrect number combinations which neither verified. Although the students in this sub-category spent less time and made fewer attempts per problem than others in the Tile-Dependent group, they still showed emerging perseverance working through multiple combinations.

Unstructured exploration, with verification. Similar to students above, the one student in this category did not follow an ordered structure while checking possibilities but was more exhaustive in his approach. While inefficient, he was able to find factors for all expressions using

a range of approaches to help check his work. For example, after incorrectly using only nine planks to factor $x^2 + 12x + 20$, he was able to find his mistake with a final pass. Averaging over three minutes per problem, algebra tiles seemed to support perseverance, providing a tool to not only explore combinations, but check his work and verify his answers.

Algorithmic. Students in this category, not only used the algebra tiles to carry out the addition, but also offloaded the processes of organizing their exploration onto the tiles by starting with a particular distribution of additive factor and moving exactly one plank to check each subsequent possibility. For example, to determine that $x^2 + 10x + 20$ had no factors, one student laid out 5 and 5 planks, then moved to 6 and 4, then 7 and 3, and so on. By using this algorithm, he knew that when working with 7 and 3, all previous factors had been attempted, hence storing the information in the tiles. Offloading this amount of cognitive load onto the tiles allowed these students to operate at a higher capacity than normal and complete problems with a high success rate. Evidence for perseverance is most prominent in this group, as their entire method was based on a structured exploration using the planks to model all possible additive combinations. Consequently, they spent more time and engaged in more attempts than any other group.

Numerical

Students in this group distinguished themselves by mentally carrying out and coordinating both addition and multiplication. Opting for mental work, they did not need to offload any of this work or cognitive demand onto the tiles or paper to support their *fluency* with the two operations or *coordinate* between them. Notably, this group of students sometimes found additive pairs and checked their multiplicative values, while other times found multiplicative factors and checked their sum. For example, when asked how he explored different combinations, a student clarified that "I go more adding, and then I go to the multiplication" showing that he preferred to find additive factors and then multiply them out. However, when working through problems, he seemed to prioritize multiplication, whispering factors of the c term, rather than additives to the b term. Although these students chose to work mentally, it was clear that conceptualizing factoring as rectangular area was an image that supported their thinking. Finally, while the students did not engage in long sustained explorations due to their arithmetic fluency, the algebra tiles aided perseverance by allowing them to explore both additive and multiplicative approaches.

Flexible

The last group consisted of two students who flexibly leveraged different resources. Depending on the nature of the problem, they explored combinations mentally like group 2, used tiles similar to group 1, and even offloaded work onto paper. For example, one student who quickly found the factors mentally to $x^2 + 12x + 20$ decided to offload her work when factoring $x^2 + 11x + 30$, starting first with additive combinations of 11 before shifting to multiplicative factors of 30 (see Figure 2). In another example, while initially believing $x^2 + 10x + 20$ factored, stating incorrectly that "6 times 4 equals 20," she was able to find her mistake by using the tiles to work through different combinations and convince herself it indeed did not factor. Similarly, the other student in this category invoked the tiles to work through different additive combinations of 10 to determine that $x^2 + 10x + 20$ did not factor. Stating each possibility out loud, she moved the longs correspondingly, seemingly to support her in keeping track and *structuring* her exploration as well as offloading some of the work involved in *coordinating* the two operations.

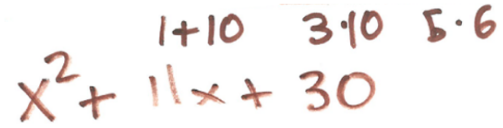

Figure 2: Symbolic Offloading of Mental Calculations

As highlighted above, while both students in this category possessed the fluency to explore different combinations mentally, they chose to use tiles when they needed support, especially in convincing themselves expressions were not factorable. To determine a quadratic is not factorable requires a more exhaustive approach, one that can be facilitated by the tiles. While students in the Numerical group correctly stated that quadratics were not factorable, they did so without providing a comprehensible argument. In contrast, the two students in the Flexible category were able to draw on and connect between more resources and representations, resulting in more sophisticated answers. The tiles also supported their perseverance. Similar to the Numerical group, they did not spend much time nor make many attempts working with factorable quadratics. However, they did leverage the tiles to methodically work through all combinations and make a convincing argument in cases that were not factorable.

Conclusion

Factoring is a difficult operation, requiring students to simultaneously carry out and coordinate two different operations. Moreover, to successfully test viable options, students must do so repeatedly and systematically. Results from this study characterize the complexities of this process and highlight distinct ways algebra tiles support overcoming these different challenges. The three different cognitive tasks we identified that compose factoring, *fluency*, *coordination*, and *structure*, help clarify why this process is difficult. In addition, the three categories of strategies identified provide a learning hierarchy of how students, depending on the strengths and weaknesses they possess, can leverage algebra tiles to progressively overcome these challenges.

The variation in approaches students employed highlights the autonomy afforded by algebra tiles and provides evidence of how these tools support perseverance. As noted in the results, students employed a range of strategies involving different modalities, including gesturing, paper, mental arithmetic. Regardless of the level of fluency students possessed, algebra tiles offered a powerful resource to persevere through each of the different challenges identified. With a specific, achievable goal of completing a rectangle, algebra tiles provide a different way for students to reach their goal. Moreover, they provide a concrete tool to explore and get immediate, actionable feedback about the accuracy of their thinking. This benefitted the Tiles-Dependent students to a great extent, as they tested and in some cases exhausted possible combinations. In contrast, students in Numerical and Flexible categories primarily used the tiles to confirm or disprove factorability. Regardless, the tiles seemed to enhance students' ability to persevere, supporting them in probing possible solutions as well as finding mistakes they had made.

Educators emphasize the importance of perseverance but often treat it as purely an individual trait. We forget that students not only need an environment that fosters such an orientation, but also tools and methods that allow repeated problem solving. Without such resources, students have limited to no means to persevere. Struggle is only productive if students possess resources to formulate and test new ideas. In contrast to traditional methods to teaching factoring where

students must rely on simply their own fluency with abstract symbols, access to algebra tiles significantly expands the approaches afforded students to factor. Moreover, using tiles to investigate patterns normalizes trial and error which inherently supports perseverance.

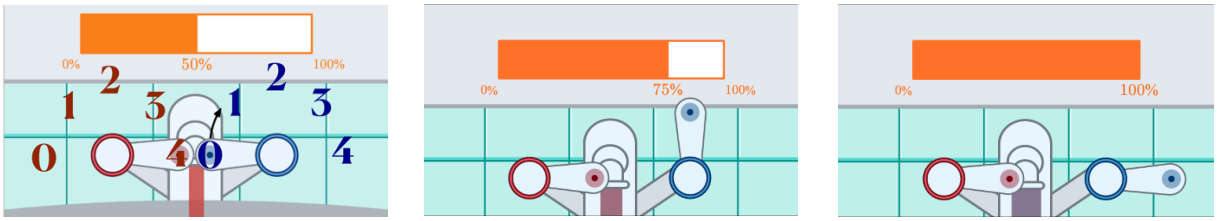
This study explores how middle school students interpret graphs representing three quantities within a two-dimensional coordinate system. While mathematics curricula typically focus on two quantities, STEM disciplines frequently require interpreting graphical representations related to more than two quantities. Using conceptual analysis and a qualitative case study of a seventh-grade student, the researchers modeled his reasoning as he engaged with a faucet task, coordinating hot/cold knob turns and water output. Findings show the student successfully leveraged multivariational reasoning and gestures to coordinate three quantities simultaneously. This work provides evidence of the existence of middle school students' ability to reason about novel graphs that represent three quantities, suggesting the potential for more sophisticated graphical curricula in middle school mathematics education.

Keywords: Mathematical Representation, Multivariational Reasoning, Middle School Education

Graphs are fundamental tools for modeling and analyzing complex situations in STEM disciplines (Knorr-Cetina & Amann, 1990; Roehrig et al., 2021; Tabachneck-Schijf et al., 1997). STEM professionals often construct and interpret graphs that simultaneously represent three or more quantities. For example, meteorologists use a psychometric diagram (Figure 2a) to represent temperature, absolute humidity, and relative humidity by using lines and curves in two-dimensional space. Interpreting such graphs entails multivariational reasoning (Jones, 2022), of which students from sixth grade (Panorkou & Germia, 2023), high school (Bagossi, 2024), and college (Jones, 2022) are capable. However, neither multivariational reasoning nor graphs representing three or more quantities are common features of U.S. math curricula (e.g., Lee & Guajardo, 2023). Further, we are unaware of studies exploring how younger students (i.e., middle school) may be able to leverage their multivariational reasoning in graphical representations.

A growing body of research highlights that students as young as middle school can leverage their reasoning about quantities to develop meanings for graphs as representing two related quantities (Ellis et al., 2015; Johnson, 2012; Paoletti et al., 2023, 2024). Further, at least some middle school students are capable of constructing more than two quantities within a situation and coordinating them in complex ways (Paoletti et al., 2025; Panorkou & Germia, 2023). Hence, we conjectured that while students can develop quantitative meanings through the act of graphing, providing them with the opportunity to first establish robust meanings for a situation involving three (or more) quantities better positions them to interpret graphs as representing

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026



these quantities, which aligns with research suggesting that deep domain knowledge helps sophisticated interpretation of graphs (Roth & Bowen, 2001).

In this report, we address the research question: *How might a middle school student interpret graphs representing three quantities within a two-dimensional (2D) coordinate system (CS)?* To answer the question, we present a case study (Yin, 2018) of one seventh-grade student's activity as he interpreted multiple points and lines in graphs that we intended to represent three quantities in a 2D CS. Before presenting our findings, we first briefly summarize relevant literature and theoretical constructs that frame our analysis, and then we describe our methodological approach and the context in which the task was posed. We conclude with a discussion of the implications of this work and directions for future research.

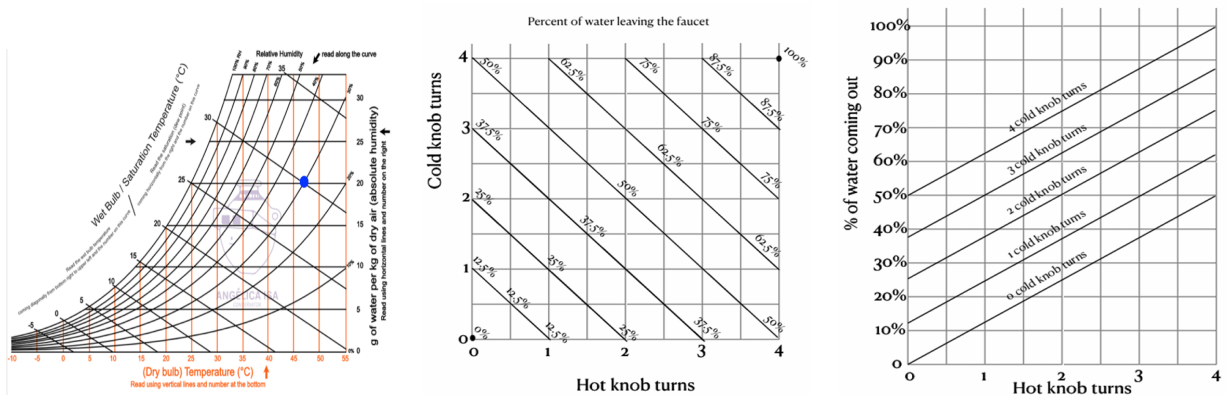
Literature Review and Theoretical Perspective: Graphs and Quantities

Graphs in school mathematics and STEM disciplines are intended to represent quantities. We adopt Steffe, Thompson, and colleagues' (e.g., Smith & Thompson, 2008; Steffe, 1991) characterization of quantities as conceptual entities that an individual constructs to organize their experiential reality (von Glasersfeld, 1995). A quantity is "someone's conceptualization of an object such that it has an attribute that could be measured" (Thompson & Carlson, 2017, p. 425). A conception of a quantity entails (at least) three interrelated components: a reference object, an orientation or directionality, and an implicit or explicit means of gauging "how much" of an attribute is present (Joshua et al., 2015; Lee, 2017, 2024; Lee et al., 2019).

To provide an example relevant to this study, consider the faucet situation in Figure 1 in which each knob can rotate from pointing left (all the way off) to pointing right (all the way on) (as shown in Figures 1a and 1c). After they describe the directionality of the turn (i.e., from off to on is positive), we tasked students with considering a way to measure each knob turn by defining a full knob turn (from left to right) as comprised of four quarter knob turns (*QKT*) (see the added numbers in Figure 1a for a recreation of how the students imagined these values).

(a) 4 Hot QKT, 0 Cold QKT: 50% water output

(b) 4 Hot QKT, 2 Cold QKT: 75% water output



(c) 4 Hot QKT, 4 Cold QKT: 100% water output

Figure 1: A Faucet Task Showing How the Amount of Hot (the Left One) and Cold QKT (the Right One) Combine to Determine the Percentage of Total Water

Most graphs in school mathematics represent two quantities in a 2D Cartesian CS (Paoletti et al., 2020; Lee & Guajardo, 2023). Although graphs are often intended to represent two changing quantities, in this report, we focus on graphs like those in Figure 2, where any given coordinate point can represent three non-varying quantities at a particular moment or state (Moore et al., 2025). Interpreting such graphs can entail multivariational reasoning (Jones, 2022; Panorkou & Germia, 2023), which refers to coordinating three or more quantities. Panorkou and Germia (2023) examined sixth-grade students' multivariational reasoning, showing how sixth-grade students can interpret and compare situations involving three related quantities. In their study,

the students did not always focus on simultaneous continuous changes. In some instances, students exhibited forms of multivariational reasoning that entailed considering discrete changes or comparing different states of the system rather than envisioning a single dynamic flow. To exemplify multivariational reasoning, consider the quantity of the total percentage of possible water (hereafter, *percent of total water*) leaving the faucet in Figure 1. Students can conceive of this quantity as a linear combination of the amount of QKT (e.g., in Figure 1b, there is 75% of total water leaving the faucet, as there is 4 Hot QKT contributing 50% of the total water and 2 Cold QKT contributing 25% of the total water). By coordinating the amounts of two independent quantities (Hot QKT, Cold QKT) in relation to a third quantity (percent of total water), students engage in multivariational reasoning.

Relatedly, Bagossi (2024) investigated high school students' reasoning about varying quantities when interpreting a psychometric diagram (Figure 2a) intended to represent temperature, absolute humidity, and relative humidity in a 2D CS. Points on the graph can be interpreted as simultaneously representing the magnitudes of three quantities in a state. Of relevance to this report, we asked students to construct or interpret points in graphs like those shown in Figure 2 (b and c), which we intended to represent the three aforementioned quantities in the faucet task (Figure 1). In Figure 2b, Hot QKT and Cold QKT serve as the horizontal and vertical axes of the CS, and the percentage of total water leaving the faucet is represented via parallel diagonal lines moving down-and-to-the-right. In Figure 2c, Hot QKT and the percentage of total water serve as the horizontal and vertical axes of the CS, and the amount of Cold QKT is represented via parallel diagonal lines moving up-and-to-the-right. Importantly, if given values of two quantities, either graph could be used to find a value of the third quantity. In the next section, we present our methods, describing the research design, participants, and data analysis.

Figure 2: (a) A Psychrometric Graph from Bagossi (2024), (b) and (c) Graphs Showing the Relationship among Three Quantities: The Amount of Hot and Cold QKT, and the Percentage of Total Water Leaving the Faucet

Methods

To address our research question, we present a qualitative case study (Yin, 2018) to describe how a seventh-grade student constructed meanings for graphs (Figure 2b and 2c) representing three quantities in the faucet context shown in Figure 1. We collected the data during the second year of a two-year teaching experiment (Steffe & Thompson, 2000) with two students (with self-selected pseudonyms), Lil Man Man (LM) and Michael Jameson (MJ) (see Table 1); for

brevity's sake, in this report, we only focus on LM's activity. Focusing on a single student allowed us to conduct a fine-grained investigation of his real-time cognitive shifts. In Year 1, the students had worked with the teacher-researcher (hereafter TR, the second author) in sixth grade to develop meanings for graphs that related to two quantities in various contexts (see Paoletti et al., 2023 for examples).

Table 1: An Overview of the Teaching Experiment Sessions over Two Years

Session	Participants	High-level Goal
1–5	LM, MJ	Construct the relationship between two quantities (Base length and Side length) and describe them via graphs within the context of playpens.
6–7	LM, MJ	Construct and reason about three quantities (Hot knob turns, Cold knob turns, and total percentage of water coming out) within the faucet task in Desmos.
8a 8b 9	LM MJ LM, MJ	Make sense of the meanings for two graphs (Figure 2b and 2c; Figure 2b was introduced first) and connect them with specific situations within the context of the faucet task.
10–12	LM, MJ	Extend to relative percentage problems in the faucet context.

Aligned with exploratory teaching (Steffe & Thompson, 2000), in Year 2, we explored how to extend LM and MJ's meanings for graphs as representing two quantities to other situations and contexts, especially contexts involving three quantities. In this report, we focus on Sessions 6–9 with LM and MJ (typically paired, but occasionally individually) within the faucet context (Figure 1). Each session lasted about 40 minutes. During each session, the TR helped the students recall the previous sessions, posed tasks we designed, and asked follow-up prompts to explore the students' reasoning. We used two cameras and screen-recording software to capture students' utterances, hand motions, written work, and computer activity.

Analysis

To analyze the data, we built models of LM's mathematics via conceptual analysis, which entails "building models of what students actually know at some specific time and what they comprehend in specific situations" (Thompson, 2008, p. 60). We began by watching the videos to identify instances where we inferred that LM coordinated more than two quantities within the CSs to answer the prompts posed by the TR. We drew on our observations of LM's gestures and utterances during these moments with a particular focus on the ways that he connected points and lines in the 2D CSs to his quantitative meanings for the three focal quantities in the faucet task. Using these instances, we generated tentative models of his reasoning processes with multiple quantities. We then returned to the data with these models in mind, examining and refining the viability of our explanations. In the results, we describe our model of LM's reasoning activities when coordinating three related quantities in 2D CSs. We mainly presented episodes from Session 8a, where LM initially exhibited meanings for the given graphs.

Results

Across Sessions 6–7, and prior to engaging with the graphs in Figure 2(b/c), LM had opportunities to conceive of Hot QKT and Cold QKT as quantities varying from zero to four (as shown in Figure 1a). Further, he understood that each knob contributed 0–50% of the total water.

In Session 8a, although the TR had introduced Figure 2b to LM, when he initially asked LM to determine one quantity when given the other two, LM would typically try to rely on his quantitative meanings for the situation to determine the third value. For example, when the TR asked LM to determine the percent of total water coming out with two Hot QKT and one Cold QKT, LM mentally calculated that two Hot QKT contributed to 25% and one Cold QKT contributed 12.5%, and added these together to get the correct value without using the graph. Hence, LM understood the situation as entailing three interrelated quantities (i.e., multivariationally).

We now provide episodes showing how LM made sense of the diagonal lines and used the given graphs (Figure 2b) to coordinate the three quantities he constructed via his multivariational reasoning. To avoid LM using his aforementioned calculational strategy, the TR opted to ask LM to determine a percentage without integer knob turns (i.e., 1.5 Hot QKT and 3 Cold QKT). Hoping to explore LM's interpretation of the novel graph, the TR also marked a point on the graph representing this situation ([1] in Figure 3a). Addressing the TR's prompt, LM looked at the graph for 20 seconds and guessed, "I think it's going to be like 56." Explaining this answer, LM put his right hand on the graph, with his first finger pointing at the 50% line and his middle finger pointing at the 62.5% line ([2] in Figure 3a). He pressed his left hand to his forehead and frowned, "I don't know how to explain it, but like…" Then, after several seconds of silence, he suddenly looked up and asked, "Wait. Are you asking what this line [*moving his finger to represent a line across the marked point, ([3] in Figure 3b)*] would be?" With affirmation from the TR, LM drew a line on the graph ([4] in Figure 3b) approximately parallel to the other fixed percentage lines. He looked at the graph and thought for 12 seconds, finally saying it would be around 56.2 or 56.3%.

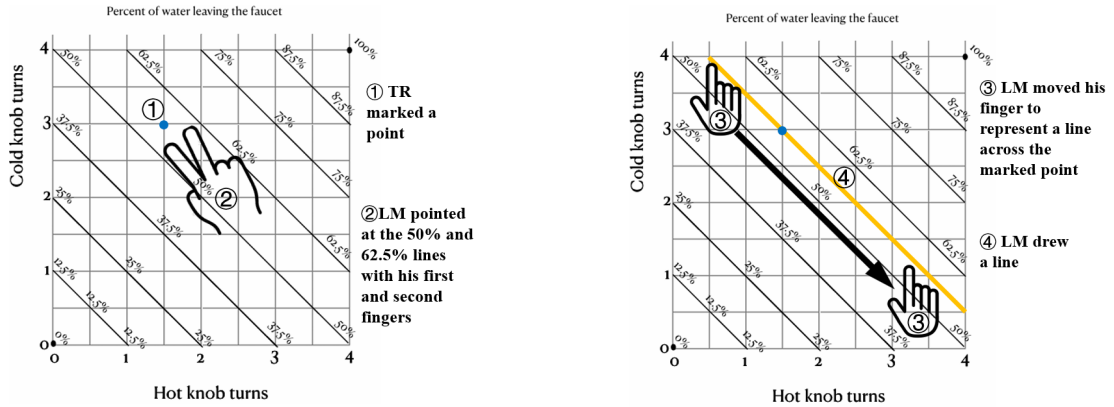

Figure 3: LM's Hand Motions Determining the Percentage of Total Water with 1.5 Hot QKT and 3 Cold QKT

We inferred that as LM engaged in effortful sensemaking of the diagonal lines related to the TR's added point, he initially approximated that the percent was halfway between 50% and 62.5% ("it's going to be like 56"). Although he initially was unsure how to articulate how he obtained this value, he eventually drew a line parallel to the 50% and 62.5% lines, indicating that this new line represented around 56.2% or 56.3%. Addressing a different task, LM drew another line representing 40% of water coming out of the faucet and identified several pairs of QKT that would result in 40% of water. Hence, LM provided evidence that he established the diagonal

lines as representing the total percent of water, but had not yet coordinated the other two quantities, Hot and Cold QKT.

The above situations entailed a focus on how to conceive the diagonal lines as representing a third quantity, and the TR also wanted to explore how LM might coordinate three quantities simultaneously in Figure 2b. Addressing the prompt, determining one QKT when given another QKT and the percentage of total water, LM again engaged in effortful sensemaking as he coordinated three quantities in a 2D CS. In particular, the TR asked LM to find out how many Hot QKT would correspond with one Cold QKT and 37.5% of the total water. Responding to this, LM looked at the graph and thought for 12 seconds before hesitantly saying, "three". As he explained his value, he realized an inconsistency, revising it immediately. He said, "I was seeing one [*pointing as in (1) in Figure 4a*] here. And then I was seeing like whatever [*motioning rightward to cross the 37.5% line as in (2) in Figure 4a*] passed here [*stopped and looked at the graph*]. Oh, two." He further explained his new answer:

> Because it is 37.5 *[using two hands and pointed at both intercepts of the 37.5% line at (0, 3) and (3, 0); (3) in Figure 4b].* It is this line over here. And then I see one *[using his left hand to point at 1 cold knob turn at (0,1) on the left axis; (4) in Figure 4b]* and two *[using his right hand to point at 2 hot knob turns at (2, 0) on the bottom axis; (5) in Figure 4b],* and then up *[moved his right hand horizontally to intersect the fixed 37.5% line; (6) in Figure 4c],* and then *[moved his left hand vertically to meet his right hand at the intersection point (2, 1) on the 37.5% line; (7) in Figure 4c]* and then meet there."

From LM's words and motions, we infer he was able to coordinate an amount of Cold QKT ([1] in Figure 4a) and a fixed percent of total water ([3] in Figure 4b) to determine the number of Hot QKT ([5] in Figure 4b). Later, LM used similar motions to solve another problem in which the percentage was not clearly represented on the graph (i.e., determining how many Cold QKT there are for 2.5 Hot QKT and 70% of total water). Hence, we inferred that LM had constructed meanings that supported him in coordinating three quantities in this 2D CS in a different way.

Given the relative ease with which LM interpreted the graph in Figure 2b, TR was curious if he would have similar success interpreting the graph in Figure 2c. As with Figure 2b, LM initially needed some time to examine the novel representation. The TR asked LM to determine how many Cold QKT would correspond to one Hot QKT and 40% of the total water. LM pointed at the one Hot QKT on the horizontal axis and moved slightly upward. He looked at the graph for eight seconds, saying, "Three [*pause for three seconds*] I think it is two, actually [*pointed at the graph*]." LM was unsure how to justify his value, so the TR asked him to mark the point he referred to on the graph (blue [leftmost] point in Figure 4d). Looking at this point, LM revised his answer again, "a little bit more than two." At that moment, the TR inferred that LM used the fact that the blue point was slightly above the line representing two Cold QKT to determine his answer. To explore this possibility, he provided additional prompts.

Next, the TR asked LM to determine the number of Hot QKT when given one Cold QKT and 30% of the total water. Addressing this, LM used his right hand to point at the one Cold QKT line and moved along with it ([1] in Figure 4d), and his left hand was pointing at 30% of total water on the vertical axis ([2] in Figure 4d). He pointed at the intersection point of the horizontal 30% line and the one Cold QKT line ([3] in Figure 4d), thinking quietly for 10 seconds. TR then drew a green dot at the point LM had indicated (Figure 4d) and asked LM if he could use this point to determine the answer. LM looked at the point, then gazed downwards from this location to the horizontal axis, saying, "Oh, it is 1.5 hot turns." We infer that LM determined the point by coordinating an amount of Cold QKT (represented by the diagonal lines) and a given percent of

total water (represented on the vertical axis) to determine the amount of Hot QKT (represented on the horizontal axis).

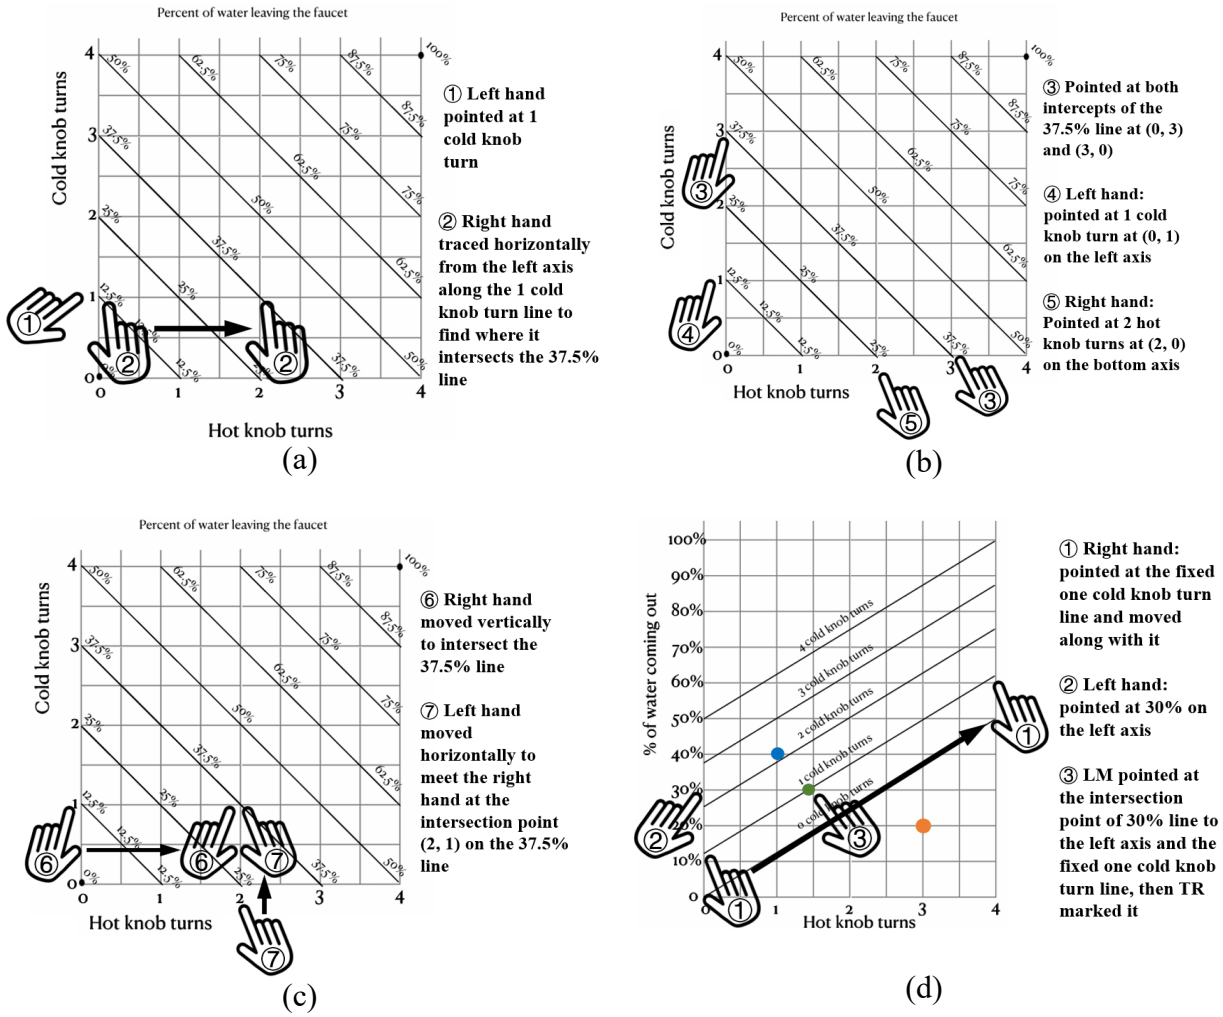

Figure 4: (a), (b), and (c) LM's Hand Motions Determining the Amount of Hot QKT with One Cold QKT and 37.5% of Total Water on Figure 2b; (d) Some Marked Points and LM's Hand Motions Determining the Amount of Hot QKT with One Cold QKT and 30% of Total Water on Figure 2c

The TR decided to see how LM would reason about a situation that was not possible within the context, but which could be marked with a point in the graph (i.e., 3 Hot QKT and 20% of total water). After hearing the prompt, LM immediately marked the point (orange (rightmost) point in Figure 4d). He quickly said, "Wait. Would it be a negative number? [*TR asked why?*] Because it is underneath the zero cold turns." We infer that LM maintained an awareness of the situational quantities he understood from his multivariational reasoning while leveraging his novel meanings for interpreting the 2D graph representing three quantities. By arguing that the answer would have to be a negative number of Cold QKT, LM provided evidence that he understood the graph as being constrained by the situational quantities. Hence, we infer that,

collectively, LM engaged in effortful sensemaking as he connected his multivariational reasoning about the situation to novel graphs representing three quantities in 2D CSs.

Discussion

Although U.S. mathematics curricula typically only ask students to reason about two quantities in 2D CSs (Lee & Guajardo, 2023), the results of this paper provide an existence proof that at least some middle school students can develop the ability to reason about three (or more) quantities in a graphical representation. Building on the work exploring multivariational reasoning with younger students (Panorkou & Germia, 2023), our findings suggest that for LM, establishing these quantitative meanings first was a critical foundation for his subsequent ability to interpret graphs as representing multiple situational quantities (Roth & Bowen, 2001). For example, LM initially relied on mental calculations based on his meanings for how each QKT contributed to the percent of total water. However, when faced with situations where mental arithmetic became difficult, he transitioned to using the novel graphical representations to determine the third quantity based on the given two quantities. However, his activity addressing the last prompt provides evidence that he remained aware of the situational quantities throughout his activity when interpreting the graphical representations.

Gestures played an important role in LM's reasoning with the graphical representations. His hand motions provided the research team with clear, observable evidence of his mental coordination processes (e.g., Figures 3 and 4). For example, in his activity in Figure 3a, he used his hands to physically model the interval required to identify the third quantity. In other prompts, he used two hands simultaneously to coordinate two given quantities to find the other (e.g., Figures 4a–c, 4b). In these cases, LM would use each hand to represent one of the two of the given quantities; by coordinating these two values in the graph, he was able to determine the value of the third quantity. These gestures were the primary vehicle through which we observed LM negotiate the relationship between the situational quantities and the graphical space.

Although we mainly focused on how LM interpreted points and lines representing quantities in a moment or state (Moore et al., 2025) that involved three quantities in a 2D CS, we note his later activity showed that reasoning about three varying quantities may be accessible to him (as in Bagossi's (2024) study). We call for future research to explore how middle school students might build on their ability to reason multivariationally about three (or more) quantities (Panorkou & Germia, 2023) to interpret graphs like those in Figure 2 as representing changing quantities in 2D CSs.

In this paper, we provided an existence proof that middle school students can reason about three quantities in a 2D CS. Such graphs are not uncommon in STEM fields (e.g., Figure 2a). Given that LM and MJ were the first two middle school students we engaged with such graphs, we wonder the extent to which middle school students are developmentally ready for more sophisticated reasoning about graphs than they are currently given opportunities to explore. That is, we conjecture that there is untapped potential for middle school students, who have been given opportunities to construct and coordinate varying quantities (Thompson & Carlson, 2017), to make sense of more complex graphs than they experience in their school experiences (Lee & Guajardo, 2023). We believe this study can serve as a starting point to create curricular tasks that leverage powerful forms of reasoning to support students in developing meanings for graphs in ways that are applicable across STEM fields.

DISPLAYED GRAPHS, CONCEIVED GRAPHS, AND HOLISTIC SHAPE THINKING

Kevin C. Moore
University of Georgia
kvcmoore@uga.edu

Research on students' and teachers' graphical reasoning has identified static (graphical) shape thinking (SGST) and emergent (graphical) shape thinking (EGST) as distinct meanings. SGST refers to reasoning about a graph as an object in-and-of-itself, essentially treating a graph as a piece of wire. EGST refers to reasoning about a graph as emerging from the covariation of two quantities. In this report, I extend the shape thinking construct to include holistic (graphical) shape thinking (HGST). An individual who engages in holistic shape thinking assimilates a graph statically while anticipating its emergence. I illustrate HGST and discuss its implications for abstracting a relationship that consists of a collection of displayed graphs.

Keywords: Graphing, Mathematical Representations, Cognition, Precalculus

Moore and Thompson (Moore, 2021; Moore & Thompson, 2015) introduced *static (graphical) shape thinking* (*SGST*) and *emergent (graphical) shape thinking* (*EGST*) to capture distinct student meanings for relationships and their graphs. SGST involves conceiving a graph as if it is essentially a malleable piece of wire (i.e., *graph-as-wire*). A student engaging in SGST assimilates a graph in terms of perceptual cues and figurative properties of shape, such as a perceived direction of drawing the graph. EGST involves conceiving a graph simultaneously in terms of what is made (i.e., a trace entailing corresponding values) and how it is made (i.e., a sustained image of quantities having covaried). A student engaging in EGST assimilates a graph as a trace in progress that is born from images and coordination of covarying quantities. A completed graph is a record of the emergent correspondence between covarying quantities (Carlson et al., 2002; Frank, 2017; Saldanha & Thompson, 1998; Thompson & Carlson, 2017).

Researchers have used SGST and EGST to characterize important differences in student reasoning across a variety of STEM contexts (e.g., Altindis, 2025; Bowe et al., 2025; Moore et al., 2019; Paoletti et al., 2023; Paoletti et al., 2024; Rodriguez et al., 2019; Tasova, 2021; Tasova & Moore, 2025; Zimmerman et al., 2024). Researchers have also used the constructs to analyze curricular materials and classroom discourse (e.g., Kimber, 2024; Lee et al., 2020; Moore, Wood, et al., 2024; Tallman et al., 2021). Other researchers have incorporated shape thinking to explore task design (e.g., Johnson et al., 2020; Margolis, 2025; Paoletti, 2019). Despite the usefulness of SGST and EGST, Moore and Thompson left potential relationships between SGST and EGST unspecified. Incorporating aspects of SGST and EGST, I introduce a third form of shape thinking—*holistic* (*graphical*) *shape thinking* (*HGST*). HGST involves an individual assimilating a graph in ways that are, on the surface, consistent with SGST. A student engaging in HGST additionally *anticipates* that any perceived properties have emergent entailments. Figurative aspects of the graph are persistently understood to be a consequence of quantities' covariation that can be reconstructed if necessary. In what follows, I provide terminology to aid in differentiating between various researcher and student conceptions of graphs. I then introduce HGST and describe how it clarifies students' actions when making sense of a graph.

Some Terminology for Discussing "The Graph"

I have used "graph" without clarifying for whose meaning I am referencing. Moving forward, I use "graph," "the graph," "function," or their variants using the terms in Table 1.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Table 1: Phrases to Distinguish among Meanings of "the graph"

Phrase	Meaning	To Whom?
Function's Graph	$(u, v)\mid u \in D_w$, $v = w(u)$ where D_w is w's domain.	Researcher
Displayed Graph	A researcher's meaning for a function's graph as presented within conventions of a particular coordinate system.	Researcher
Student's Displayed Graph	A student's meaning for what the researcher takes to be a displayed graph.	Student
Student's Conceived Graph	A student's conception of properties that are common to all displayed graphs constituting their conceived graph.	Student

Function's graph refers to a researcher's conception of coupling quantities' values sans a specific coordinate system. *Displayed graph* refers to a researcher's understanding of a function's graph as displayed within the conventions of a particular coordinate system. Speaking of a function's graph as distinct from a displayed graph enables characterizing a function's mathematical properties common to all displayed graphs of that function. An example is the function's graph defined by $f(x) = 3x$, $-\infty < x < \infty$. The function f's graph appears as a line when displayed in rectangular coordinates and as a spiral when displayed in polar coordinates. Both displayed graphs are produced by a trace so that the output value of f varies at a constant rate of change of three with respect to f's argument; this quantitative relationship is a property of the function's graph and hence of all displayed graphs. Figurative properties can differ across displayed graphs as influenced by the coordinate systems' conventions. Another example is the sine function's graph: $\{(u, v)\mid -\infty < u < \infty, v = \sin(u)\}$. The sine function's graph has the property that v increases by decreasing amounts as u increases by equal successive amounts for $0 \le u \le \pi/2$. **Error! Reference source not found.** presents six displayed graphs of the sine function, each representing the interplay between the sine function's graph and the conventions of the coordinate system in which its graph is displayed. **Error! Reference source not found.**e uses two displayed graphs to show that changes in the sine function's output value decrease with equal successive increases in its argument. Each displayed graph entails the same quantitative relationship but differs in its figurative properties.

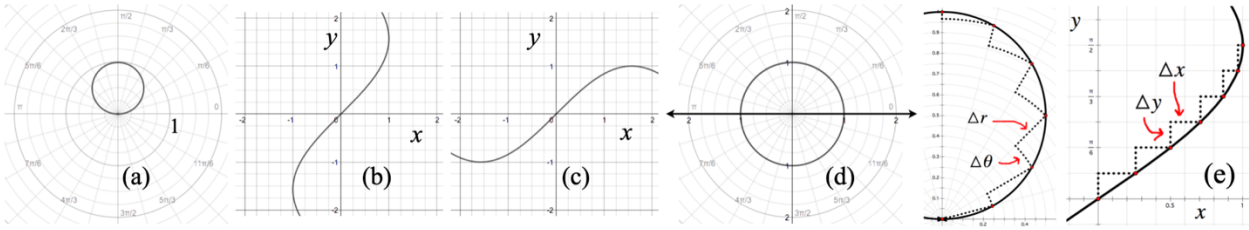

Figure 1: Six Displayed Graphs of $(u, v)\mid -\infty < u < \infty$, v = sin($u$): (a) $r = \sin(\theta)$ in Polar Coordinates; (b-c) $x = \sin(y)$ and y = sin(x) in Rectangular Coordinates; (d) $y = \sin(\theta)$ in a Combination of a Polar and Rectangular Coordinates; (e) Two Graphs Annotated to Identify v Increasing by Decreasing Amounts as u Increases by Equal Successive Amounts

Student's displayed graph refers to a student's understanding of what the researcher perceives to be a displayed graph. I use **Error! Reference source not found.** to illustrate the

advantage of distinguishing between a researcher's displayed graph and student's displayed graph. I conceive **Error! Reference source not found.**a-e to be displayed graphs created by the covariation defined by $v = \sin(u)$. A student can conceive each displayed graph to be created by that covariation, thus establishing a set of displayed graphs they understand as "sine graphs" (Moore et al., 2013). Alternatively, a student might assign each displayed graph a unique association between perceived shape and name. In such a case, the student may only establish **Error! Reference source not found.**c as "the sine graph" (Moore, 2021). To that student, the other displayed graphs could not be "the sine graph" because they are not the shape associated with sine. The student's displayed graph **Error! Reference source not found.**c is a shape associated with a name.

I use *student's conceived graph* to mean that a student has constructed a meaning that entails (potentially mathematical) properties that are invariant among a set of displayed graphs. Returning to the previous examples, it would be accurate to say the latter student's conceived graph for "sine" was a learned shape, and their set of displayed graphs was technically a single displayed graph that was the known shape. On the other hand, a student who conceives **Error! Reference source not found.**a-e to be displayed graphs created by the covariation defined by $v = \sin(u)$ has constructed a conceived graph for "sine" that is an invariant property of covariation. The student's set of displayed graphs is any displayed graph that enables representing the invariant property.

Further drawing attention to the need to differentiate between a researcher's and student's realities, I note that a "function's graph" and "displayed graph" are shorthand for a *researcher's function's graph* and a *researcher's displayed graph*, respectively. Also, a "student's displayed graph" and a "student's conceived graph" are technically shorthand for a *researcher model of a student's displayed graph* and a *researcher model of a student's conceived graph*, respectively. These technicalities acknowledge and honor students' autonomy and their independent mathematical realities by making it clear that a researcher cannot escape her or his personal reality (Hackenberg, 2010; Hackenberg et al., 2024).

Holistic (Graphical) Shape Thinking

In introducing SGST as distinct from EGST, Moore and Thompson (2015) noted that images of covariation are absent from *in-the-moment* understandings established via SGST. As an example, SGST could involve understanding the displayed graph in Figurea as having a greater slope than that in Figureb because it is more vertical or steeper. The reasoner might use this perceptual association to *infer* that over some interval of x, y increases by more in Figurea than in Figureb (e.g., the steeper the line, the more y increases). More generally, the perceptual properties constructed via SGST can *imply* learned information about quantities' values and generalized relationships (e.g., formulas and pairs or tables of values), but images of quantities and their relationships are not organic to the *in-the-moment* assimilation of a displayed graph.

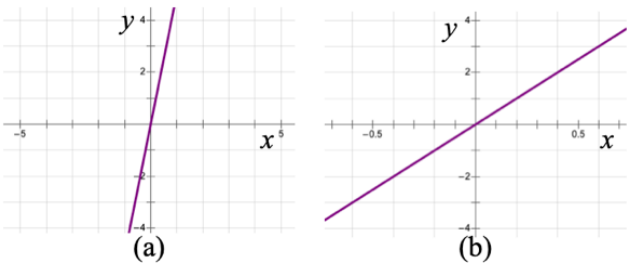

Figure 2: Two Displayed Graphs

In addition to an image of quantities and their relationships being absent from *in-the-moment* understandings of a displayed graph, SGST is also absent of anticipating a graph as an emergent trace of covariation (Moore, 2021). Consider an alternative case in which emergent schemes of covariation are in the space of implications established via reasoning that resembles SGST. That is, consider a student who assimilates a displayed graph based on perceptual or figurative properties but anticipates those properties are a consequence of an emergent trace of covariation. For instance, having inferred that Figurea has a greater slope than that in Figureb because it is steeper, the individual anticipates that this is a consequence of the magnitude change along the *y*-axis being greater in Figurea than in Figureb for an equivalent magnitude change along the *x*-axes. Here, the individual anticipates the displayed graphs as emergent traces of covariation to which *all inferences* about quantities and their relationships are tied. I term such reasoning *holistic graphical shape thinking* (*HGST*), which involves a student assimilating a displayed graph as if it is an object in-and-of-itself (i.e., SGST) while persistently anticipating an emergent trace of covariation of which all properties are a consequence (i.e., EGST).

A student thinking holistically assimilates or recalls displayed graphs "all at once" on the basis of perceived shape and learned facts, but they do so with the persistent understanding that displayed graphs are visual records of emergent schemes. Shape and associated facts are thus understood as inseparable from a displayed graph's emergence and the individual can reconstruct a graph's emergence if necessary. For instance, upon encountering a novel coordinate system or experiencing confusion, the student might choose to enact those schemes. Or the individual might enact emergent schemes to further explore the relationship conveyed by a displayed graph. For instance, to further compare Figurea and Figureb, the individual might conceive each displayed graph in terms of the quantities' covariation along the axes and recognize the rate of change of y with respect to x is equivalent. To further illustrate HGST, I use Rico's response to the task of graphing $\theta = \sin(r)$ in the polar coordinate system. I suggest the reader attempt to construct a displayed graph prior to reading more or viewing the solution (see Figure 5 at the end of the paper).

Rico was a former high school mathematics teacher engaged in an empirical study. A colleague and I had determined he had not previously associated this formula with a displayed polar graph. We used $\theta = \sin(r)$ because to envision a displayed graph, one must accommodate to two departures from customary actions. The first departure is that, customarily, θ (a point's angular direction coordinate) is a function's argument and r (a point's radial coordinate) is a function's output value. This is reversed in $\theta = \sin(r)$. The second departure is that an argument to sine is customarily defined as an angle measure, but r is a distance in the PCS. One must therefore translate a value of r from being a polar distance to being an angle measure (Figure 3a) and then envision the sine of that angle measure (Figure 3b) to produce a direction (another angle measure) as the function's output value (Figure 3c). As Stevens (2026) noted, this process necessitates uniting those two values into a pair that determines a coordinate point on the function's displayed graph determines a point on the function's displayed graph (Figure 3d).

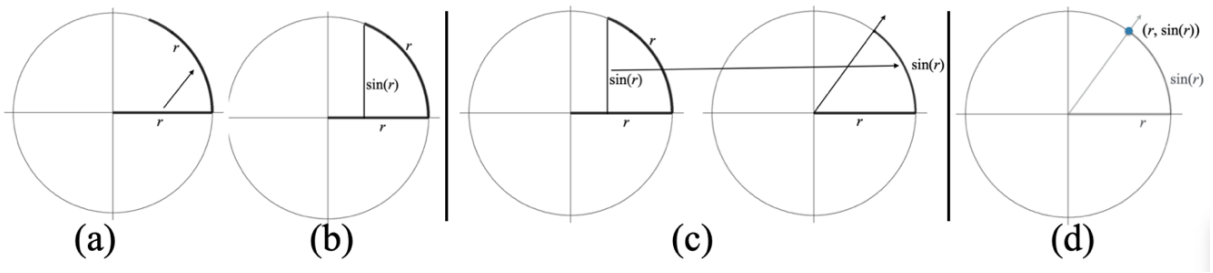

Figure 3: (a) A Radial Distance Becomes an Arc, (b) Envisioning sin(*r*) for a Value of *r*, (c) sin(*r*) Becomes a Direction and Arc, (d) Uniting the Values of *r* and sin(*r*). See http://bit.ly/RicosGraph for an animated version of this process

To construct the graph of $\theta = \sin(r)$ displayed in polar coordinates, one must keep these processes intact as one also envisions the behavior of sin(*r*) as the value of *r* varies. Rico did all of this. Table 2 summarizes the phases of Rico's construction of a displayed graph for $\theta = \sin(r)$.

Table 2: Summary of Rico's Construction of a Displayed Graph for $\theta = \sin(r)$

Phase	Summarizing Rico's Statements	Commentary
1	*r* is distance from origin. θ is angle measure. I must interpret *r* as an arc length. *r* starts at 0 and increases in length.	Rico envisions the mental actions depicted in Figure 3a.
2	I need a reference point. As *r* increases, vertical displacement (*i.e., sin(r)*) increases. I envision a spiral kinda like this (*see Figure 4a*).	Rico coordinates actions depicted in Figure 3a–d while imagining that the value of *r* increases.
3	I know how *r* and θ are related in Cartesian coordinates (*see Figure 4b*). I know as *r* increases, angle measure increases because how the sine function behaves. I know that when $r = \pi/2$ the angle measure (*i.e.,* θ) will be largest (*i.e.,* 1).	Rico's sketched Cartesian graph reminds him of sine's covariation. This recalled shape, for Rico, symbolizes emergent covariational properties. He uses this to anticipate sketching a polar graph that will not exceed a polar angle of 1 because at $r = \pi/2$, sin(*r*) is 1 and sin(*r*) then decreases in value.
4	As that distance (*i.e., r*) increases, the angle measure (*i.e.,* θ) increases toward $\pi/2$ (*see Figure 4d*).	Rico uses the anticipated covariational relationship to coordinate θ and *r* in the polar coordinate system.
5	As that distance (*i.e., r*) increases [*beyond π/2*], the angle measure (*i.e.,* θ) will decrease. Something like this (*see Figure 4e*).	Rico continues to use the anticipated covariation to covary values of *r* and values of θ according to the relational structure depicted in Figure 3a–d.
6	So as I get further from the origin, that's corresponding with an increasing angle measure (*i.e.,* θ) up to one radian. That happens when $r = \pi/2$. As *r* gets larger, the angle measure (*i.e.,* θ) starts to decrease, until it stops decreasing when θ is –1 [*and the cycle repeats*] (*see Figure 4f*).	Rico has constructed an image of covariation of *r* and θ. His image relies on a recalled shape with anticipated emergent properties (sine behavior) that he dis-embed from Cartesian coordinates and re-embeds emergently in polar coordinates.

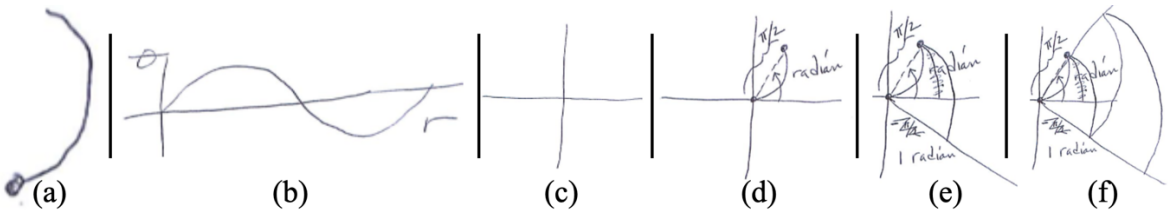

Figure 4: Rico's Progression of Work

I underscore two aspects of Rico's reasoning. First, Rico's construction of the graph displayed in polar coordinates involved a persistent focus on the emergence of covarying quantities. When identifying points, it was for the purpose of partitioning intervals of covariation. Second, Rico drew the Cartesian graph all-at-once from memory. This is consistent with SGST on the surface, but Rico's recalled shape symbolized emergent properties associated with sine that he was able to use to construct the polar graph. Such actions are indicative of HGST. In summary, he coordinated his static image of a Cartesian sine graph with an anticipated covariational relationship to reason emergently and construct a displayed graph of $\theta = \sin(r)$ so that it had the same emergent properties. Rico's actions illustrate that HGST is productive for recalling previously constructed displayed graphs in ways that are flexible for novel displayed graphs.

Indexical Reasoning and Accommodation

There is an important difference between HGST and EGST. With respect to a student inferring information about quantities and their relationships via HGST, the *in-the-moment* associations with quantities and their relationships are indexical: a particular shape or properties of shape *imply* something about how the displayed graph emerged through quantities' covariation. Recalling a displayed graph holistically enabled Rico to anticipate covariational properties, but he did not enact them *until* he constructed a novel displayed graph; EGST involves *in-the-moment enactments* of covariation operations so that quantities and their covariation are organic to a student's displayed graph; a student thinking emergently constructs quantities and they operate on them. On the other hand, HGST is such that quantities and their covariation including how the displayed graph emerges through that covariation are implications of a student conceiving a displayed graph. HGST enabled Rico to recall a displayed graph and then enact its emergent entailments in a novel setting, illustrating the blend of SGST and EGST.

When compared to SGST, me and my colleagues' work suggest EGST and HGST are more productive for students accommodating to novel experiences HGST and SGST each refer to students assimilating displayed graphs on the basis of previously experienced shapes and learned associations. In the case of HGST, these learned associations have emergent entailments. In the case of SGST, these learned associations act strictly as pointers between memorized shapes and learned facts in the form of function rules, numerical patterns, etc. These quantitative associations are not derived from a displayed graph's emergence. Hence, students who are constrained to SGST hold meanings suited for displayed graphs consisting of shapes and associations that have been previously experienced and learned. SGST requires maintaining the representational system in which the shape associations were learned; shapes typically change when representational conventions are changed. For instance, Rico's recalled shape for the sine relationship is based on a particular orientation of variables and positive values. If his meaning

for “the sine graph” was constrained to that static recollection, some other meaning would be necessary for accommodating to a novel graphing experience that departs from the context in which that shape association had been constructed.

The differences between HGST and SGST provide an important distinction to students’ graphical resources (Rodriguez & Jones, 2024). In the moment of enactment, both HGST and SGST appear as similar graphical resources (i.e., steepness as rate with Figure). However, they differ in their space of implications and, hence, their generativity beyond *their in-the-moment* enactment; that enactment is not indicative of the same cognitive structure. SGST’s implicative space consists of learned associations and facts, even when there are generalized properties between values in them. HGST’s implicative space can entail the same learned associations and facts, but those are understood as a consequence of the schemes of covariation organic to a displayed graph’s emergence. Because schemes and images of covariation are generative (Moore et al., 2013; Thompson, 2011), HGST and its emergent entailments thus provide resources suited to unpacking in novel graphing experiences. They also promote understanding when those resources are relevant (Moore et al., 2022; Moore et al., 2013; Moore, Stevens, et al., 2024). Relatedly, and taking on an Action-Process-Object-Schemas framing (Breidenbach et al., 1992), HGST might form a productive object-level meaning, with process- and action-level meanings being rooted in the anticipation and enactment of covariational schemes, respectively. By enacting EGST, a student can constitute a trace in any coordinate system orientation as representative of the same covariational relationship. Returning to steepness as rate, thinking holistically and emergently supports understanding that such a resource is constrained to Cartesian conventions, but that the underlying emergent schemes of covariation are not.

Shape Thinking and Conceived Graphs

Each shape thinking form characterizes the meanings that constitute students’ displayed graphs. The shape thinking forms are also useful when describing students’ conceived graphs. Recall that a student’s conceived graph is a meaning that entails (potentially mathematical) properties that they conceive as invariant among a set of displayed graphs. No matter shape thinking form, in some instances a student’s meaning is constrained to a particular displayed graph and thus entangled with their understanding of a specific coordinate system. I do not use “constrained” with a negative connotation. A student’s initial graphing experiences are necessarily tied to a specific coordinate system and orientation, and there is little reason to expect such a student to anticipate displayed graphs with equivalent properties in alternative coordinate systems. Hence, I use “constrained” to mean that a student’s conceived graph *is* a displayed graph so that it does not occur to the student that particular features or attributes (whether static, emergent, or holistic) could be displayed in another coordinate system or orientation. For instance, had Rico never experienced the polar coordinate system, his conceived graph may have been constrained to that which he recalled via HGST.

Regardless of form, a student’s conceived graph could also be such that its elements are not constrained to a particular displayed graph. In such a case, a student’s conceived graph consists of an equivalence class of displayed graphs formed by the properties understood as invariant among them. With respect to SGST, a student’s conceived graph could be constituted by a collection of named graph-as-wires, figurative cues and features that each shape maintains, and the anticipation of graph-as-wires in other coordinate systems that maintain compatible figurative cues and features. To illustrate, via reasoning statically, a student could construct a conceived graph that is constituted by figurative features common to each shape in **Error! Reference source not found.**. For instance, the student could perceive the drawing of each

displayed graph in terms of repeating the same shape (e.g., repeatedly drawing a wave from left-to-right or repeatedly drawing a circle counterclockwise). The figurative action of repeatedly drawing a pattern constitutes the student's conceived graph. Furthermore, the student could anticipate that displayed graphs in other not yet experienced coordinate systems and orientations would also consist of that figurative action.

In the case EGST, a student's conceived graph is constituted by a covariational relationship that each trace is understood as representing within its respective coordinate system. The student might also anticipate the existence of emergent traces in other coordinate systems and orientations that capture an equivalent covariational relationship within those coordinate constraints. To illustrate, a student could construct a conceived graph that is constituted by the collection of emergent traces in **Error! Reference source not found.** and a covariational relationship common to each shape. The student could understand each trace in terms of some quantity A's value having an increase to 1 as quantity B's value increases from 0 to $\pi/2$. Moreover, the student could understand each trace in terms of quantity A's increase having a decreasing magnitude for successive equal increases in quantity B over that same interval of values. If not constrained to particular displayed graphs, the student anticipates that displayed graphs in other (possibly not yet experienced) coordinate systems and orientations maintain this covariational relationship. The student understands that a displayed graph is always the interplay between their conceived graph (i.e., a covariational relationship) and the structure of the corresponding coordinate system.

With respect to HGST, a student's conceived graph could be constituted by a collection of shapes that the student treats as if they are objects in-and-of-themselves. The student could perceive perceptual cues and visual features that each shape maintains and anticipate that shapes exist in other coordinate systems that maintain compatible features. The student's conceived graph *also* entails a covariational relationship they can enact emergently to produce each associated shape. The student could also anticipate that shapes exist in other coordinate systems that could be produced by thinking emergently within that coordinate system. Another feature of HGST could be that if a student's conceived graph involves generalized perceptual features, the student anticipates these features are a consequence of covariational properties represented within respective coordinate systems. To illustrate this latter point, a student's conceived graph $(u, v)| -\infty < u < \infty, v = \sin(u)$ could entail anticipating that symmetry must occur no matter the coordinate system: the displayed graphs in **Error! Reference source not found.** have symmetry with respect to $\theta = \pi/2$, $x = \pi/2$, $y = \pi/2$, and $\theta = \pi/2$, respectively. The student would also understand that these features of symmetry are a product of v covarying in the same manner with respect to u increasing *or* decreasing from $u = \pi/2$, thus establishing covariational symmetry with respect to $u = \pi/2$.

Closing

Moore and Thompson (Moore, 2021; Moore & Thompson, 2015) left unclear whether a student may use SGST and EGST in-tandem. I identify a productive form of reasoning is that which appears to be SGST but technically has emergent entailments. HGST is not simply the combination of SGST and EGST. SGST involves figurative and thematic properties of displayed graphs and does not capture meanings that include emergent entailments. HGST resembles SGST in-the-moment of assimilation, but assimilation via HGST involves anticipating its emergent entailments. These entailments enable accommodating to novel displayed graphs through enacting mental operations that maintain covariational properties. HGST positions figurative properties strictly as consequences of quantities' covariation. Moving forward, an area

of inquiry is how students construct and leverage meanings consistent with HGST, particularly as they abstract a conceived graph from a displayed graph collection. It is also important to understand learning environments that support SGST, EGST, or HGST. With researchers illustrating the short- and long-term importances of covariational reasoning, it is imperative that we understand how to support EGST (e.g., Paoletti et al., 2023; Tasova & Moore, 2025) and HGST so that students' graphical meanings and resources include emergent entailments.

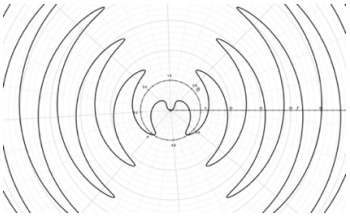

Figure 5: A Fifth Displayed Graph of $(u, v)| -\infty < u < \infty, v = \sin(u), \theta = \sin(r)$

HOW MIDDLE SCHOOL STUDENTS INTERPRET GRAPHS IN A ROBOTICS CONTEXT

Halil I. Tasova
California State University San Bernardino
halil.tasova@csusb.edu

This study examines how sixth-grade students interpreted distance–time graphs while programming Sphero robots in a robotics-based algebra task. Using the constructs of figurative and operative thinking, I analyzed classroom episodes to describe students' emerging meanings for graphs and unit rate. Findings show three patterns: (1) iconic translation (graph as a path of motion), (2) blended reasoning that coordinated quantities while preserving graph shape, and (3) quantitatively coherent reinterpretations that matched distance–time values but obscured the slope–speed relationship. Whole-class discussion supported students in identifying unit rate from graphs and connecting speed and slope across representations

Keywords: Algebra and Algebraic Thinking, Mathematical Representations

The ability to construct and interpret graphs is central to middle school mathematics and foundational for later learning in algebra and STEM disciplines (Carlson et al., 2002; Thompson & Carlson, 2017). Graphs support reasoning about functional relationships, rate of change, and covariation (Carlson et al., 2022; Ellis, 2011; Johnson, 2015). However, research shows that many students interpret graphs primarily as visual shapes or pictures of situation rather than as representations of quantitative relationships (Clement, 1989; Johnson et al., 2020; Monk, 1992; Moore & Thompson, 2015). Such interpretations limit students' ability to reason about rate, invariance, and underlying structure (Frank, 2016; Moore et al., 2014; Tasova & Moore; 2020).

From a quantitative and covariational reasoning perspective, productive graphing involves coordinating two varying quantities and conceiving a graph as a trace emerging from their covariation (Moore & Thompson, 2015; Moore, 2021; Saldanha & Thompson, 1998). Yet instruction often emphasizes symbolic procedures or static representations, providing limited opportunities for students to experience graphs as dynamically generated objects (Frank, 2016; Moore, Silverman, et al., 2019; Paoletti et al., 2022). As a result, students may foreground perceptual shape features over quantitative coordination (Moore & Thompson, 2015; Moore, Stevens, et al., 2019).

Programmable robots, such as Sphero, offer an embodied context in which motion is measurable and directly programmable (see https://www.youtube.com/watch?v=f21VLjQwtoY). When students code a robot's speed and duration, they engage with distance, time, and rate dynamically. Such environments may support students in developing productive and powerful ways of graphing.

This study investigates how middle school students interpret distance–time graphs in a robotics-based instructional setting, with particular attention to how figurative and operative aspects of thought emerge and interact during the activity. By examining students' classroom reasoning as they program and analyze robot motion, this study extends prior work on students' graphical meanings (Frank, 2017; Moore & Thompson, 2015; Paoletti et al., 2023; Tasova & Moore, 2025) into an embodied robotics context.

Theoretical Perspective

Radical Constructivism and Instructional Design

This study is grounded in radical constructivism (von Glasersfeld, 1995), which views knowledge as constructed rather than transmitted. Learning involves reorganizing prior meanings through cycles of action, reflection, and adaptation. In classrooms, such reorganization is often triggered by perturbations—moments when students' expectations conflict with outcomes encountered through tasks, tools, or discourse. From this perspective, instructional design aims not to deliver correct explanations but to create environments that provoke reflection and reconstruction of students' mathematical ideas. Tasks, tools, and discourse are designed to surface students' existing meanings and create opportunities to reorganize them.

Didactic Objects

To conceptualize instructional design, this study draws on Thompson's (2002) notion of a *didactic object*—a deliberately designed "thing to talk about" that supports reflective mathematical discourse. An object is not inherently didactic; it becomes so when used to foreground specific mathematical relationships and operations. Its effectiveness lies not in its physical or digital form, but in the mental actions it invites students to enact (Bowers et al., 2011). Designing a didactic object therefore requires identifying the mental operations students must coordinate to interpret a situation productively. In this study, programmable robots and graphs function as didactic objects when used to organize classroom discourse around distance, time, rate, and covariation. The robot's motion provides a shared object of reflection through which students can examine quantitative relationships.

Figurative and Operative Thinking

To analyze students' reasoning within this environment, this study draws on the distinction between figurative and operative thinking (Moore, Stevens et al., 2019; 2024; Thompson, 1985). Figurative thinking foregrounds perceptual features and imagery. In graphing contexts, students may attend primarily to shape, direction, or visual resemblance, engaging in iconic translations that map a situation directly onto a graph (Monk, 1992). Such reasoning privileges appearance over quantitative and covariational reasoning.

Operative thinking, in contrast, foregrounds coordinated mental actions. A graph is conceived as a trace emerging from the covariation of quantities (e.g., emergent shape thinking; Moore, 2021). From this perspective, slope represents a relationship between changes, and graphical shape is understood as a consequence of those coordinated changes.

In this study, the distinction between figurative and operative thinking serves as an analytic lens for examining how students interpret graphs in a robotics-based setting. Specifically, I investigate how engagement with programmable robots surfaces students' figurative and operative interpretations and how these interpretations interact with, and sometimes reorganize into, more operative, quantitatively grounded reasoning.

Methods

Participants and Setting

Participants were 87 sixth-grade students enrolled in a four-day Summer STEM Camp at a southwestern public university. Students attended one 75-minute robotics-mathematics session per day in four class periods (approximately 20–24 students each). Although students had prior exposure to coordinate graphs and proportional relationships, most had not previously worked with programmable robots. This study focuses on a proportional distance–time graphing task implemented on Day 1.

Data Collection

All lessons were video recorded using three cameras: one focused on the teacher (the author), one on a focal group of four students, and one capturing whole-class activity, including student discussions, gestures, robot motion, and written work. Students' written responses and coding sequences were also collected. The multi-angle recordings allowed me to examine not only students' verbal explanations, but also their embodied interactions with the robots, gestures toward graphs, and revisions of code during the "code–watch–revise" cycles.

Data Analysis

Analysis proceeded in three phases. First, selected small-group discussions were transcribed and reviewed alongside video to preserve gestures, intonation, and interactions with robots. Second, episodes were identified in which students interpreted graphs to determine motion, discussed robot placement or starting conditions, determined speed from graphs, or experienced disagreement about what the graph represented. These moments were selected because they made students' graphing meanings visible.

Third, episodes were analyzed using figurative and operative thinking as analytic lenses. We examined whether students foregrounded perceptual features (e.g., shape-matching, iconic translation) or coordinated quantities such as distance and time (e.g., identifying speed as distance per second). Particular attention was given to moments of tension or perturbation. Rather than quantifying frequencies, the analysis characterizes qualitatively distinct ways of thinking that emerged and how instructional interactions supported or constrained them.

The Robotics Graphing Task

Students began with a 10–15-minute warm-up in which they experimented with a single "roll" command that specifies heading, speed (cm/s), and duration (seconds; see Figure1). I briefly elicit students' ideas about what each parameter controls before they begin experimenting. This initial exploration was intended to familiarize students with the robot interface while also establishing key quantitative relationships among speed, time, and distance through embodied activity.

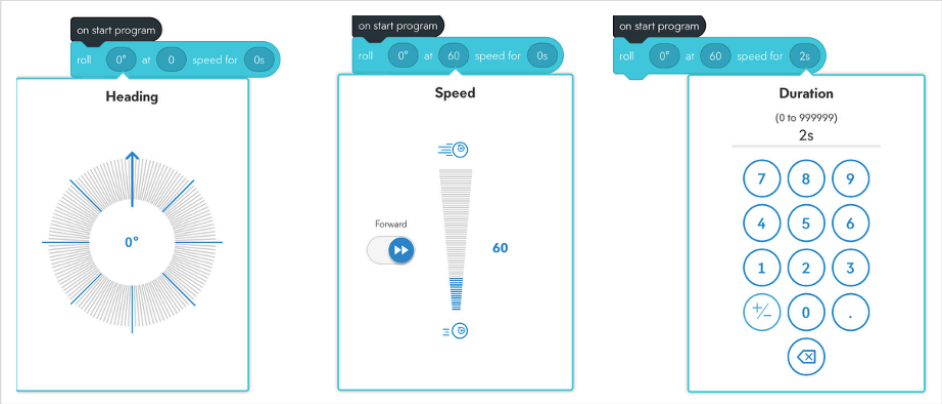

Figure 1: The Roll Block in the Sphero Edu App, Showing Controls for Variables

The focal task was situated in a beach context (Figure 2a). Students were given a distance–time graph containing two proportional linear functions (Robot A and Robot B; Figure 2b). Working in groups of four (two pairs), each pair programmed one robot to match one of the lines. Robots were required to move straight toward the water and to start simultaneously, so that students could directly compare the motions produced by their programs.

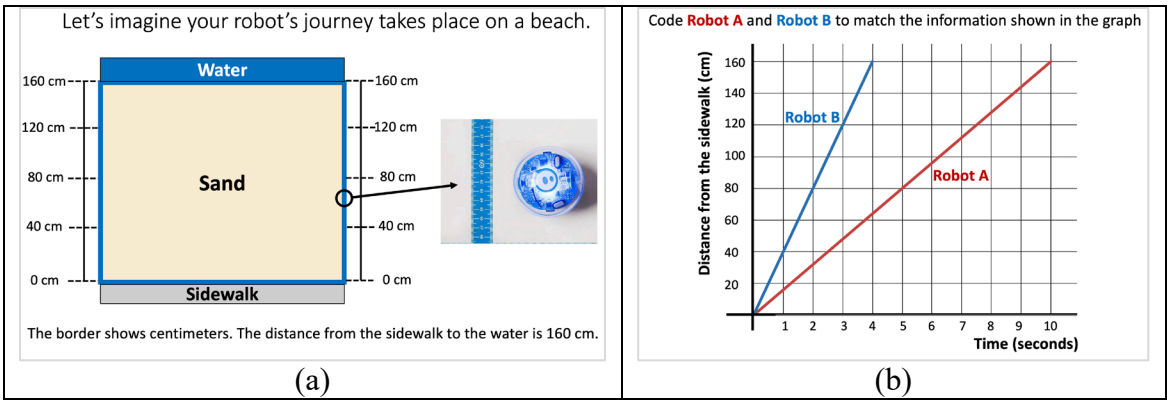

Figure 2: (a) Floor Setup for the Robotics Graphing Task Showing the Beach Context, (b) Distance–Time Graph Used by Students to Program and Compare Robot A and Robot B

Students engaged in iterative "code–watch–revise" cycles: they wrote code, observed robot motion, compared the motion to the graph, and revised accordingly. When both robots were released at the same time, differences in their motions became publicly visible, creating natural opportunities for comparison and discussion. Figure 5 shows an example of a correct solution.

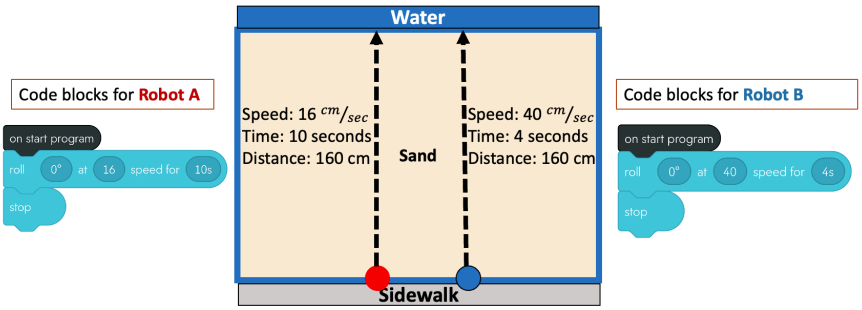

Figure 3: Correct Motion Paths and Code Blocks for Robots A and B

The robot–graph pairing functioned as a didactic object (Thompson, 2002). The graph itself was not inherently didactic; rather, it became didactic through the classroom conversations it supported and the specific mathematical relationships it helped bring into focus. Robot motion also provided immediate, non-evaluative feedback. When a programmed motion did not align with the graph, discrepancies between expectation and outcome created perturbations that anchored discussion around quantitative relationships.

The task was designed with two instructional intentions.

Goal 1: Support students in interpreting graphs as representations of covariation. A central goal of the task was to support students in interpreting graphs as records of two quantities varying simultaneously (Moore, 2021), rather than as pictures of situation (Clement, 1989) or spatial paths (Johnson et al., 2020). The design constraints (straight movement and simultaneous start) intentionally disrupted shape-matching interpretations and created occasions for students to confront what, exactly, a distance–time graph is representing. Classroom discussion focused students' attention on identifying the quantities represented on the axes and interpreting individual points as simultaneous values of distance and time. For example, students were asked:

At 3 seconds, how far is the robot from the sidewalk? Could the robot be in different physical locations and still be the same distance from the sidewalk? If the graph starts at (0,0), what does that tell us about where the robot begins? Such questions were designed to foreground quantitative relationships and point-wise interpretation rather than iconic interpretations.

Goal 2: Support students in identifying unit rate from the graph. A second goal was to support students in identifying unit rate (speed) directly from the graph and relating it to slope. Because students had to determine a speed value that would allow the robot to travel a given distance in a specified amount of time, they were pressed to interpret the graph quantitatively rather than rely only on trial-and-error. Some students initially adjusted speed values until the robot arrived at the water at the correct time. When this occurred, instructional questions redirected attention to the graph: *How much distance does the robot travel in 1 second? Can you find a point where time equals 1? What does that y-value tell you? Can you choose any point on the line and use its coordinates to find the speed? If you divide distance by time, what does that number represent in this situation?* Through such prompts in small groups, students were supported in interpreting speed as distance per second and relating that quantity to the constant of proportionality represented by the graph (i.e., [1, *r*] where *r* is the unit rate).

Results

Figurative and Operative Thinking in the Robotics Task

Analysis of classroom episodes revealed three recurring ways students initially approached the Robotics Graphing Task. These approaches illustrate varying combinations of figurative and operative aspects of thought.

Iconic translation: Purely figurative thinking. A subset of students interpreted the graph as a picture of the robot's physical path (Figure 4a). Rather than attending to the quantities represented on the axes, these students attempted to make the robot trace the shape of the line. For example, one group examined the slanted line on the graph and immediately positioned their robot diagonally across the sand, saying, "It [*referring to the robot*] should go like that." This reflects figurative reasoning in which perceptual shape guided interpretation.

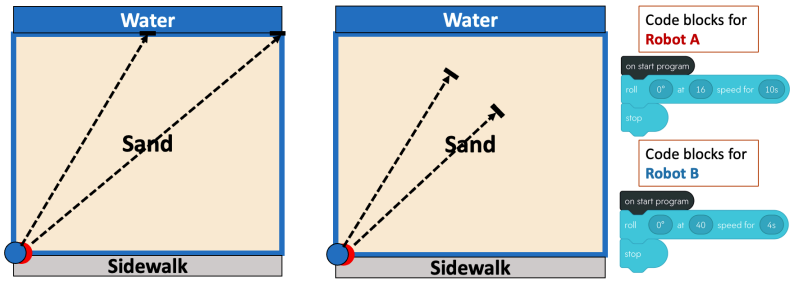

Figure 4: (a) Iconic Translation: Robots Tracing the Visual Shape of the Graph; (b) Coordinating Quantities While Preserving the Graph's Shape in the Robot's Motion

After observing this pattern in several groups during the first period, I added an explicit constraint to the task: the robots should move *straight* from the sidewalk to the water. This constraint, combined with the requirement that both robots start simultaneously, created immediate tension. When reminded that the robot must move straight toward the water, one student responded, "But the graph is not straight," providing evidence of an iconic translation.

Students who attempted to match the shape of the graph spatially on the floor also encountered tension when both robots could not occupy the same starting location. Some groups resolved this tension by taking turns, despite the instruction to start simultaneously. However, this moment opened space for discussion about what the origin (0,0) represents: not a physical corner of the sand, but zero seconds and zero distance from the sidewalk. These tensions became opportunities to discuss what the graph actually represents—not the physical path of the robot on the sand, but a relationship between time and distance from the sidewalk.

Mixed reasoning: Coordinating quantities while preserving shape. A second group of students correctly identified information from the graph—such as the time it takes each robot to reach the water from the sidewalk—yet still attempted to preserve the graph's visual shape in the robot's physical motion (Figure 4b). For instance, one student stated, "This one [Robot B] takes 4 seconds. … this one [Robot A] 10 seconds." However, they positioned the robots at an angle to mimic the shape of the lines. After testing, the robots did not reach the water at the intended time, which surprised these students. One student said, "we used 40 but it didn't work" referring to the speed value they had identified from the graph for Robot B.

Here, students coordinated time, distance, and speed (operative elements) while simultaneously relying on shape-matching (figurative elements). Because the diagonal motion increased the actual distance traveled, the robots failed to reach the water within the specified time. I did not anticipate this form of reasoning—simultaneously quantitative and perceptual—in the original conceptual analysis. It illustrates that figurative and operative thinking are not mutually exclusive; students may blend them within the *same* activity.

To resolve this perturbation, one student suggested, "more speed," indicating a shift toward adjusting the quantitative relationship. They implemented a trial-and-error strategy to determine a speed value that would allow the robot to reach the water in 4 or 10 seconds. I elaborate on this approach in the following section.

Mixed reasoning: Coordinating distance–time information while preserving shape. A third pattern emerged in which students simultaneously matched the visual shape of the graph and satisfied the time and distance information shown on the graph, but in a way that altered the intended quantitative relationship (Figure 5a). Like the second group, these students positioned the robot diagonally so that its physical path resembled the shape of the graph. However, unlike the second group, they ensured in their first attempt that the robot reached the water at the correct time (e.g., 4 seconds or 10 seconds, see the code blocks in Figure 5a).

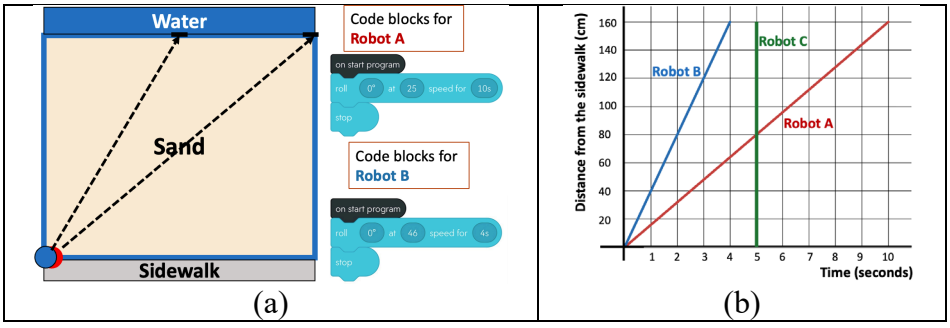

Figure 5: (a) Coordinating Distance-Time Information While preserving the Graph's Shape in the Robot's Motion; (b) An Additional Graph Introduced to Further Probe Student Thinking

Because the diagonal path was longer than the straight distance from the sidewalk to the water, students increased the robot's speed to compensate for the additional distance traveled. As a result, two things were simultaneously true: (i) at each second, the robot's distance from the sidewalk matched the y-value of the graph, and (ii) the robot arrived at the water at the correct time. However, the robot's actual path length differed from what was intended, and therefore its speed differed from the slope (unit rate) represented by the graph.

In this way, students satisfied the information displayed in the graph while preserving its visual shape in the robot's motion. The graph's quantitative information was respected locally (distance from the sidewalk over time), yet the global relationship between slope and speed was obscured. This pattern reveals a blended form of figurative and operative reasoning. Students coordinated time and distance (operative elements) yet continued to rely on shape-matching interpretations (figurative elements).

For this group of students, perturbing their reasoning proved more challenging because their response was mathematically valid and coherent within their reinterpretation of the situation. After observing this pattern across multiple class periods, I introduced a new graph on the same coordinate plane (see Figure 5b) to further probe students' thinking. The goal was to help students recognize that the shape of the graph alone does not determine the robot's physical motion.

When shown a vertical line at five seconds, students offered competing interpretations. One student said, "It [Robot C] goes straight [*gesturing a direct path from sidewalk to the water*]." When asked, "How long does the robot move?" the student responded, "Five seconds," but appeared unsure. After a brief pause, he added, "It doesn't say… it's like same time." Another student interjected, "It can't be [inaudible] at the same time." Here, operative reasoning emerged spontaneously. Some students recognized that a vertical line on a distance–time graph implies multiple distances at the same time, which is physically impossible. This discussion further highlighted the distinction between perceiving a graph as a shape and understanding it as a representation of relationships between quantities.

Unit Rate and Graphs

Whereas the first section focused on the interplay of figurative and operative thinking, this section highlights how students reasoned about unit rate within the task.

Some students initially relied on trial-and-error strategies when determining the speed of the robots: "Try 30." "No, too slow." "Try 45." Rather than correcting these attempts, I posed questions to redirect attention to the graph. For example, I asked, "How far does it [Robot B] go in one second?" A student responded while looking at the graph, "At one second… it's 40." When asked, "What does that tell you?" the student replied, "here [*pointing to the 40 cm mark on the floor*] in one second."

In several groups, students began locating the point where time equals 1 and reading the corresponding distance. Others selected a point and divided distance by time (e.g., 120 divided by 3 is 40, which is the value of the speed in centimeter per second).

Following small-group activity, I brought the class together to consolidate key mathematical ideas. The goal of this discussion was to connect different strategies students had used to determine the robot's speed (i.e., unit rate) from the graph. I projected student work illustrating two common approaches (Figure 6): (i) identifying the speed by reading the distance at one second and (ii) selecting a point on the line and dividing distance by time. I asked students to compare these strategies: "How are these two methods the same?" and "What does each one tell

us about the robots?" Through this comparison, students began to see that both strategies reveal the same quantity: distance per second (e.g., "it goes 40 every second").

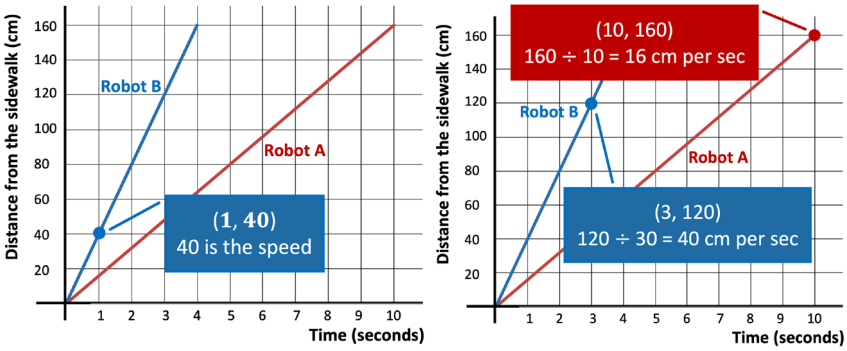

Figure 6: Student Work Highlighting Two Common Approaches for Determining Speed from Proportional Graphs

I then introduced slope triangles as a third strategy. Drawing vertical and horizontal changes on each graph, I asked students to compute their ratio and see how that compared to the robot's speed. This discussion made the connection between speed and slope explicit: both represent the ratio of vertical change to horizontal change. For sixth-grade students, this discussion was intended as an early introduction to slope. For students with prior exposure, it reinforced slope as a rate of change.

Discussion and Conclusion

This study examined how middle school students engaged in figurative and operative aspects of thought while participating in a robotics-based graphing task. With respect to Goal 1, findings show that many students initially interpreted graphs iconically, treating them as pictures of motion rather than representations of covarying quantities. The task constraints—requiring straight movement and simultaneous starts—surfaced these interpretations and created productive tensions. A key contribution of this study is the illustration of blended reasoning: students coordinated time and distance while simultaneously preserving the graph's visual shape in the robot's motion. Although prior research has documented iconic translations and quantitative interpretations separately, fewer studies have illustrated this kind of simultaneous blending of figurative and operative aspects of thought within the same activity. Here, students maintained locally correct distance–time reasoning while reorganizing the physical situation in ways that obscured the intended unit-rate/slope relationship.

With respect to Goal 2, although many students began with iconic or trial-and-error strategies, several articulated quantitative interpretations by the end of the lesson and identified unit rate directly from the graph. Whole-class discussions helped students connect reading the value at one second, dividing distance by time, and using slope triangles. These moments suggest that the robotics environment supported connections between speed, unit rate, and slope. At the same time, this study does not claim that students developed deep or durable understandings of these relationships within a single lesson. Such understandings require sustained opportunities for reflection and practice. Moreover, because of space limitations, this paper focused primarily on moments when figurative and operative meanings co-occurred, rather than tracing individual shifts in detail—an important direction for future research.

Several limitations should be acknowledged. This study was conducted in a whole-classroom setting during a summer camp. While this context allowed observation of a wide range of student reasoning within a short period of time, it did not permit the same depth of individual analysis possible in one-on-one or small-group teaching experiments. Although classroom discussions often culminated in apparent consensus, shared verbal agreement does not guarantee shared meaning. I did not collect systematic individual-level evidence to determine the extent to which each student internalized the targeted quantitative interpretations of graphs or unit rate.

Future research could strengthen this line of inquiry by incorporating individual written reflections, such as asking students to independently explain the story a graph tells or to write code based solely on a graph without testing it physically. Such artifacts would provide insight into the internal coherence of students' reasoning. In addition, implementing pre- and post-assessments could help document changes in students' graphing meanings over time. Finally, conducting individual or small-group teaching experiments using the Robotics Graphing Task would allow for the construction of detailed models of student thinking and support iterative refinement of the task as a didactic object.

An analysis is presented on the potential use of algebra tiles in university level algebra courses for students in economics and administration. Based on the identification of common difficulties in solving quadratic equation problems, an exploratory sequence of introductory algebra activities using algebra tiles is implemented to examine whether the favorable results reported at previous educational levels can be extended to higher education. The exploration es analyzed from an instrumentalist perspective, and hypotheses are proposed for instructional design with an emphasis on the instrumental genesis of algebra tiles.

Keywords: Algebra and Algebraic Thinking, Cognition, Design Experiments, Undergraduate Education

Introduction

Quadratic equations are part of students' educational trajectory from basic education through university. However, having encountered them previously does not guarantee a deep understanding of the concept or the ability to use them meaningfully in specific disciplinary contexts.

In university Algebra courses for Economics and Business Administration programs, it is common to find students who recognize the algebraic procedures associated with this type of equation but experience difficulties in interpreting them, representing them graphically, or relating them to problems involving cost, revenue, or profit analysis. In many cases, quadratic equations appear as a curricular requirement rather than as a tool for solving real situations in the administrative field.

Based on the identification of this issue, it is evident that algebraic difficulties developed during secondary education (ages 12–15) persist among university students, as reported by several authors, including Didiş (2023), O'Connor and Norton (2022), and López and colleagues (2016). In particular, the emphasis on algorithmic methods, such as the quadratic formula for solving the general equation $ax^2 + b\,x + c = 0$ or the strategy of completing the square, reveals that students often struggle to formulate equations, interpret their solutions, and especially understand the different types of solutions and how the elements of an algorithmic process relate to the original problem or situation. Therefore, this project proposes the use of concrete materials, specifically algebra tiles, as support for an experimental teaching approach aimed at addressing learning difficulties associated with solving quadratic equations in Economics and Business Administration contexts.

With this overall goal, and as part of the preliminary analysis conducted to generate instructional design principles, we present here the results of an exploratory study carried out with the specific objective of confirming students' difficulties in solving algebraic equation problems and assessing the feasibility of implementing instruction supported using algebra tiles with undergraduate students.

Theoretical Framework

This study is grounded in the Theory of Instrumental Genesis and Instrumental Orchestration developed by Luc Trouche (2004). From this perspective, an artifact such as algebra tiles does not automatically become a learning instrument simply because it is present in the classroom. For this transformation to occur, students must develop utilization schemes that integrate action, meaning, and intention. The analysis focuses primarily on Instrumental Genesis in terms of two interrelated processes. On the one hand, the artifact influences the student's activity (instrumentation); on the other hand, the student adapts, reorganizes, and reinterprets the artifact according to their purposes (instrumentalization). This process is not immediate; rather, it is gradually constructed through interaction, reflection, and discussion about how the material is used. To describe the development of instrumental genesis, we also draw on the distinction between *usage schemes* and *instrumented action schemes*. Usage schemes refer to the actions and strategies that a user develops to handle an artifact and transform it into an instrument. These schemes may be individual or collective and evolve through practice. They are oriented toward the basic management of the artifact and include the actions and knowledge required to operate its fundamental functions (Trouche, 2004).

Instrumented action schemes are schemes that combine mathematical knowledge with the use of an artifact to solve problems. In other words, they involve not only knowing how to operate the tool but also integrating it into the process of mathematical reasoning. These schemes are more complex and are oriented toward the accomplishment of specific tasks using the artifact. They require a deeper integration of knowledge, as they are based on how the user employs the artifact to carry out a particular activity.

Therefore, the preliminary analysis presented here focused on observing the types of schemes that participating students developed while using algebra tiles to represent and solve quadratic equations.

On the other hand, the possibilities for instruction are analyzed in terms of Instrumental Orchestration. Within this approach and based on the identification of the characteristics of instrumental genesis, potential teaching strategies that could be implemented to foster instrumental genesis in the mathematics classroom are examined, as suggested by previous studies conducted by Tasayco (2021), Manrique (2020), and Jiménez and Mejía (2015).

In this project, we are interested in identifying which instructional strategies could be implemented to support the teaching of quadratic equations using artifacts such as algebra tiles.

Methodology

We worked with a group of first-semester students enrolled in the bachelor's degree in business administration, implementing two activities adapted from a textbook based on the use of algebra tiles (Wah & Picciotto, 1994). In the first activity, students were expected to recognize, through direct manipulation, how each tile represents a unit, a variable, or a quadratic term, and to establish relationships between these concrete pieces and the algebraic expressions that are traditionally written on the board. Rather than memorizing equivalences, the aim was for students to understand the meaning of each representation and how they are connected to one another.

In the second activity, students were invited to build on the work completed in the first activity and use the algebra tiles to construct the corresponding equation. The intention was for them to visualize how a quadratic expression emerges from the multiplication of two linear expressions and based on that construction, to use the material as a tool for analyzing and solving the equation (Figure 1).

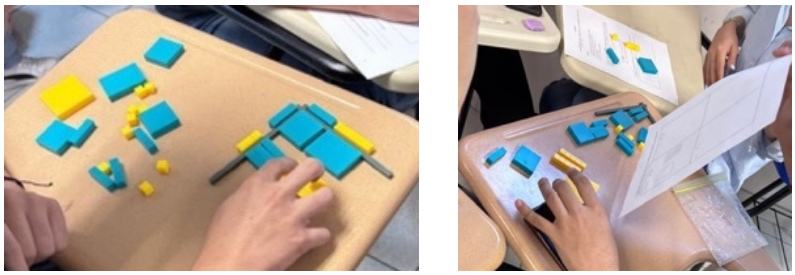

Figure 1: Students Carrying Out the Binomial Multiplication Activity

The adaptation of the instructional materials included the design of structured sessions that allowed students to actively interact with the manipulatives and digital tools, promoting the collective construction of meaning. During the implementation, classroom dynamics emphasized collaborative work and guided discussion, so that interactions among teams encouraged the comparison of strategies, the validation of results, and joint reflection on different ways of approaching the proposed problems.

Based on the implementation of the activities, the classroom sessions were analyzed to identify the difficulties involved in systematizing the expected uses of algebra tiles for formulating and solving equations.

Instrumental Orchestration is characterized by three fundamental concepts: didactical configuration, mode of exploitation, and didactical performance.

Didactical configuration refers to the structure of the learning environment, that is, the way in which tools, students, and tasks are organized. In this project, this structure involves collaborative work with algebra tiles and digital exploration using GeoGebra, focused on contextualized problems related to Business Administration.

Mode of exploitation concerns the way in which the teacher implements the task, including providing instructions, posing questions, and engaging students in the learning process. Rather than intervening directly in the completion of the task, the teacher supports students through guiding questions that encourage reflection without explicitly solving the activities for them.

Finally, didactical performance refers to the teacher's actual practice during the lesson. It takes place throughout the intervention as the teacher responds to unexpected events, develops new strategies, and facilitates student participation. At this stage, the teacher's flexibility becomes evident, as well as their ability to guide the process of Instrumental Genesis according to the emerging needs of the group.

One of the instrumental orchestrations selected was the screen-board linkage orchestration. It should be noted that this type of orchestration represents a classroom management strategy in which the teacher orchestrates, guides, and coordinates the connections among students, technological resources, and traditional instructional media.

General Description of the Exploratory Study

When carrying out the adapted activities, the algebra tiles function as a manipulable model that allows students to physically organize the terms x^2, x, and the constants, while establishing connections between concrete and symbolic representations. This process supports the development of modeling and algebraic reasoning skills through the identification of factors and the structuring of procedures (Picciotto, 1990). The tangible outcome of the activity is the correct

construction of a quadratic expression from the combination of two linear expressions, demonstrating that algebra tiles serve not only as a visual aid but also as a representation of the underlying algebraic structure of a quadratic equation.

The usage scheme includes implicit rules such as grouping tiles of the same type, forming rectangles or squares to represent products, and arranging the tiles in ways that reflect the structure of the equation. This scheme functions as an internalized set of instructions, guiding students in how to manipulate the tiles meaningfully before developing their own strategies. In the first activity, it was observed that some students were able to identify the relationship between the tiles representing the unit, the variable, and the squared term, establishing correspondences between the concrete objects and their symbolic representations. However, during the development of the tasks, a recurring difficulty emerged related to *elementary operations*, particularly the addition and multiplication of like terms. Some students experienced difficulties when performing basic calculations or when establishing equivalences between the concrete representation and the corresponding symbolic expression. The second activity focused on constructing basic configurations with algebra tiles to represent products of linear expressions. Students worked in teams. The purpose of this exercise was for them to identify the structure of quadratic expressions generated by the multiplication of two linear expressions and to verbalize their observations regarding the relationships between the concrete construction and its corresponding symbolic expression. At least two teams were able to explain, in their own words, the meaning of the representations they had constructed with the algebra tiles, as can be seen in Figure 2.

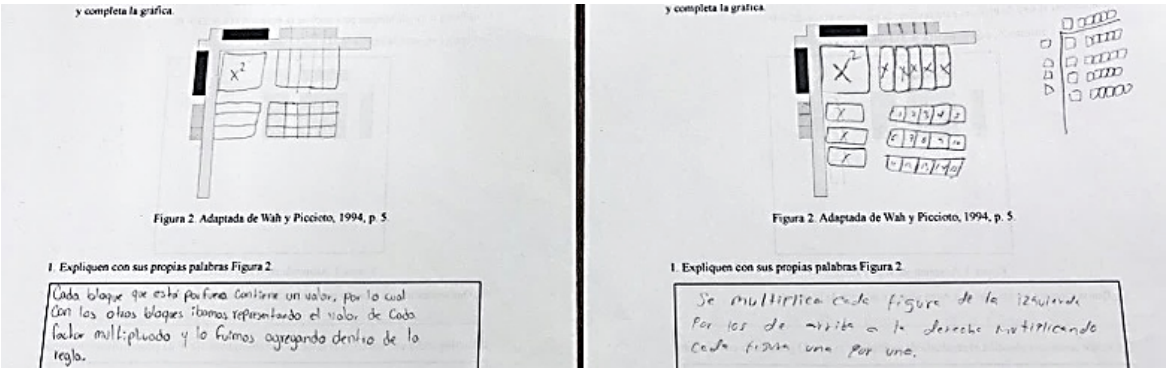

Figure 2: Responses from Two Student Teams to Activity 2

Among the most relevant aspects that emerged during the exploratory implementation were the students' active and collaborative participation, their interest in manipulating the material, and their willingness to discuss and compare procedures. However, difficulties in elementary operations also became evident, particularly in the simplification of algebraic expressions.

Final Considerations

Unlike primary and secondary education contexts, where algebra tiles are typically used to support the initial understanding of algebraic concepts and the development of basic operational skills, in this proposal manipulable materials are incorporated into a higher education setting with different purposes. Their use is intended to support mathematical modeling processes related to situations encountered in the fields of Economics and Business Administration, promoting the interpretation, analysis, and validation of results in contextualized problems.

In this sense, the manipulable material is neither an end in itself nor a strategy for introducing elementary algebra. Rather, it serves as a pedagogical resource that supports the construction of meaning around quadratic equations and their application in professional contexts, enabling students to establish connections among concrete, algebraic, and contextual representations that are relevant to their university education.

It is worth noting that, the exploratory experience revealed that the use of algebra tiles transformed the usual classroom dynamics. While working with the material, students did not simply carry out procedures; they began discussing how to organize the tiles, questioning the results they obtained, and explaining their decisions to their peers. On several occasions, disagreements emerged that required them to revisit and revise their constructions. However, it became evident that specific strategies are needed to promote the development of both usage schemes and instrumented action schemes. In this regard, the project will draw on the taxonomy proposed by Paul Drijvers et al. (2010, p. 998).

Regarding the design hypotheses, we propose that the development of usage schemes can begin through activities involving binomial multiplication, quadratic equations, and their solution using the "completing the square" procedure. Furthermore, we hypothesize that the construction of an instrumented action scheme for factorization could be fostered based on these usage schemes, supported by figural strategies for completing squares.

Rather than confirming that the manipulative material automatically "improves" learning, what was observed is that it creates a space in which algebraic relationships can be discussed through concrete representations before being formalized symbolically. This observation has led us to design four instructional sequences aimed at providing continuity and greater depth to what began as an exploratory experience.

TYPES OF INTERNAL STRUGGLES WHEN SOLVING A GROWING PATTERN TASK

Sumeyra Karatas

Students' internal struggles that are not visible to teachers when solving a growing pattern task were explored. Seven 11th-grade students solved a pattern problem by thinking aloud. Data in the form of recorded interviews and students' work were analyzed by using open coding. Task-based clinical interviews documented the most frequent struggles when solving a growing pattern task. The most repeated struggle was writing a quadratic equation. The other struggles were knowledge of variables, generalization for growing patterns, drawing the figures, use of multiple representations, and reading the full question.

Keywords: Internal Struggle, Pattern Task, Clinical Interviews

Pattern tasks, such as table tiling or growing patterns, place significant cognitive demands on students, requiring them to recognize patterns, coordinate visual and numerical information, and generalize relationships across stages (Hiebert & Grouws, 2007; Beatty et al., 2013). These demands often give rise to struggle, both externally, as evidenced in errors or requests for clarification, and internally, as uncertainty or difficulty in forming rules (Warshauer, 2015). Wilkie (2022) argued that figural pattern generalizations are cognitively demanding for students, and noticing the functional relationship and symbolizing requires meaningful development. Guided by the framework of productive struggle, which views learning as developing understanding through sustained sense-making with challenging tasks (Hiebert & Grouws, 2007; National Council of Teachers of Mathematics [NCTM], 2014), this study informed the design of the patterning task and the analysis of students' difficulties in generalizing patterns and formulating quadratic equations. Building on the literature, this paper focuses on answering the research question: *How do students experience internal struggles when solving a growing pattern generalization task during task-based clinical interviews?*

Research Settings and Participants

Seven 11th-grade students, four males and three females, attending a public charter high school in the central-south United States, participated in this study. Each student has previously completed Algebra 1 and Geometry. Before the interviews, students covered the linear and quadratic functions in the Algebra 2 course. The researcher and the teacher identified the students based on classroom observations. Students who showed signs of struggle during class or who could not progress on the tasks were selected for an interview. The participants remained anonymous.

Methods, Materials, Data Collection, and Analysis

A task-based clinical interview (Clement, 2000; Goldin, 1997) was used to provide a detailed picture of participants' internal struggles and individual differences. During the interview, students sat down with the researcher, who set up and explained the task and asked them questions to probe their thinking as they worked. Participants had access to calculators, manipulatives, and other classroom materials. Participants were asked to vocalize the words in

their minds while working on the task. The table tiles task (Mathematics Assessment Resource Service [MARS], 2015) was used for the interview (see Figure 1).

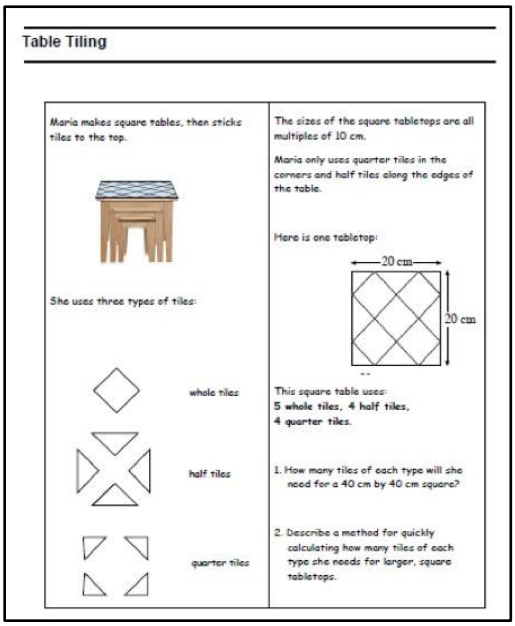

Figure 1: Table Tile Task (Adapted from MARS, 2015)

The first part of the task aims to evaluate whether students can draw a 40-by-40 square using the given figure as a reference and identify the number of each tile type. The second problem was designed to gather data on students' awareness of examining data, identifying patterns, and generalizing those patterns using multiple representations. Participants were also asked to describe which part of the task was most challenging. The seven clinical interviews lasted approximately one hour. The data consist of transcribed video and audio recordings from seven interviews, along with participants' written data.

The data were analyzed using content analysis to yield a concise yet broad description of students' struggles. Interview transcripts were analyzed using *open coding* (Corbin & Strauss, 2014). The interview data were analyzed in three stages suggested by Creswell (2015): preparing the data by transcribing, reducing the data into themes through coding, and representing the data. The authors noted that patterns are identified through data familiarization, data coding, and theme development and revision. After creating the initial codes from the interview transcripts, an Excel file was used to organize and document extracts and their corresponding codes, and to support line-by-line coding of the students' clinical interviews. In the next step, themes were developed by identifying significant patterns of meaning.

Preliminary Results

These qualitative data focused on seven high school students working through the table-tiling task. The task-based video-recorded clinical interviews were analyzed, and 115 codes were created from the video recording transcripts. Struggle codes were merged into main themes (see Table 1). Confusion, overthinking, and difficulty identifying half and quarter tiles were classified into the "other" theme. In this paper, we focus specifically on the most frequent struggle identified among participants: writing a quadratic equation.

Table 1: The Distribution of the Codes for Struggle

Struggles	Number of Codes	Frequency
Writing a quadratic equation	42	37%
Knowledge of variables	19	17%
Generalization for growing patterns	16	14%
Drawing the figures	16	14%
Use of multiple representations	9	8%
Read the full question	9	8%
Other	4	3%

Writing a Quadratic Equation

The categories in Table 1 were developed through iterative qualitative coding and represent the primary observable difficulty in a student response. As shown in Table 1, the most frequent struggle theme was writing quadratic equations. The table tiles question asked for a method to determine the number of tiles for larger square tabletops. Students needed to create an equation to determine the number of each tile type given the tabletop size. For the number of quarter tiles, students were expected to obtain a constant function; for the number of half tiles, a linear function; and for the number of whole tiles, a quadratic function. All students easily found the number of quarter tiles because it was constant. All seven participants constructed a table to represent the pattern. Six participants used the slope-intercept form to generate a linear equation representing the number of half tiles. While Student 1 (a typical response) made a connection between a geometric pattern and an algebraic equation, Student 7 constructed two separate tables: one in which x denoted the figure number and another in which x denoted the length of the figure (see Figure 2).

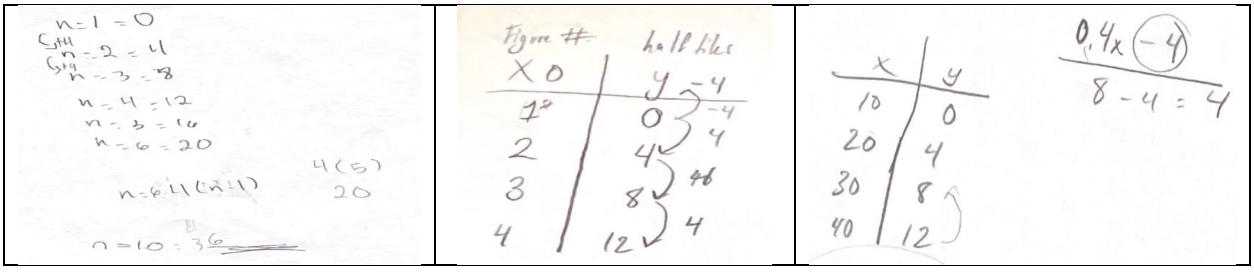

Figure 2: Student 1's Solution (Left) and Student 7's Solution (Middle and Right)

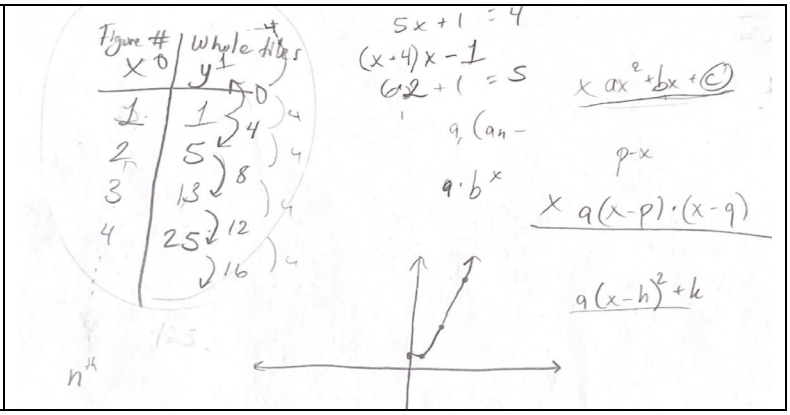
On the other hand, all seven participants struggled to write the equation for the whole tiles, which is a quadratic equation. Only Student 1 got the algebraic equation for the whole tiles without using a calculator. Student 1 made a connection between a geometric pattern and an algebraic equation. Four participants used the TI-Nspire calculator to determine the equation for the whole tiles by entering the table values. However, they did not initially recognize that the relationship required a quadratic equation; they only realized this after the calculator generated a quadratic model. Students stated that writing the equation for whole tiles was the most challenging part of the task. Figure 3 presents an excerpt from the clinical interview that highlights the difficulties students encountered in determining the quadratic equation for the

number of whole tiles. Student 3 created a table and sketched a graph for the whole tiles, attempted to identify a pattern, and used three forms of quadratic equations; however, he was unable to determine how to construct the equation (see Figure 3). Students experienced difficulty identifying the appropriate type of equation.



Student 3: "The most challenging part for me is finding the equation for the whole tiles. Since it is a quadratic equation, it feels unfamiliar. We cannot determine the vertex; we do not know the zeros, the values of *a*, *b*, and *c*, or the *y*-intercept. These three equations do not help."	

Figure 3: An Excerpt from Student 3's Interview (Left) and Student 3's Solution (Right)

After constructing the table, all participants recognized that a linear function described the half tiles. However, none explicitly stated that a quadratic function was needed for the whole tiles. Some students also assumed that if the relationship was not linear, it might be exponential, limiting their reasoning to only two options: linear or exponential.

Conclusion and Implications

Participants in the interviews demonstrated that writing a quadratic equation to generalize a growing pattern was the most challenging part of a high-demanding problem-solving task. One of the main issues in identifying the quadratic pattern was students' inability to connect the geometric features of the shape—such as how it was constructed—to how that structure could inform the development of an equation. Quadratics are the first non-linear polynomials that students find difficult, and they struggle to understand what makes a relationship quadratic (Suominen, 2018). This finding aligns with Orton et al.'s (1999) study, in which participants were able to translate the values into a table but were not successful in finding the equation. The analysis revealed that students experience significant difficulty in generalizing patterns, particularly when the underlying relationship is non-linear. These findings may help teachers support students' understanding of quadratic functions through tasks that connect geometric and algebraic representations. A limitation of this study is its small, context-specific sample. Future research could examine how individual and collaborative settings influence students' ability to generalize patterns and formulate equations.

MIDDLE SCHOOL STUDENTS' CONSTRUCTION AND COMPREHENSION OF MATHEMATICAL VARIABLES

Elisabeth Oberst
George Fox University
eoberst23@georgefox.edu

Sarah Kerrigan
George Fox University
skerrigan@georgefox.edu

This pilot study investigates the ways middle school students understand mathematical variables in the contexts of numeric solving, graphing, and using equations. Three students participated in a series of task-based interviews designed to highlight various components of their understanding of variable. A framework was developed throughout the interviews to classify a student's variable understanding as either fixed, chunky, complete, or as a combination of two of the categories. The results indicate that a student's understanding of variables within equations and within graphing are often different. Additionally, a student's use of equations may be the strongest indicator of their understanding of variables across all contexts.

Keywords: Algebra and Algebraic Thinking, Middle School Education

Across mathematics, variable plays a central role, and thus it is important that students have a full and accurate understanding of what a variable is. This understanding can begin developing as early as elementary school but is addressed more in the middle grades. How a middle-school student conceptualizes variable affects the way they construct general middle-school mathematics and thus can have a lasting impact on their experience in mathematics as a whole (Bush & Karp, 2013; Hackenberg & Lee, 2015; Lee, 2018; Smith & Thompson, 2008). Although research has investigated how students handle the concept of variation and covariation more generally (Castillo-Garsow et. al., 2013; Thompson & Carlson, 2017), there is no universally agreed-upon definition of a variable within mathematics, making it difficult to determine a student's understanding of variable (Ely & Adams, 2012). More research is needed to better help students develop a robust understanding of variable. As such, in this pilot study, we iteratively refined a framework of students' variable understanding based on their approaches to tasks involving variables. More specifically, we were seeking to answer the question: In what ways does a student's approach to solving for numeric values, graphing relations, and using equations indicate their level of variable understanding?

Theoretical Framework

Approach

Student understanding of mathematical concepts will be viewed through a Neo-Piagetian framework, in that an individual's conceptualizations are based on mental objects and operations (Castillo-Garsow et al., 2013; Johnson, 2016). Patterns in student explanations and behaviors are indicative of their underlying reasoning and conceptualizations. The researchers generalized these patterns and used them to iteratively refine a framework for variable understanding.

Defining Quantitative Reasoning

Quantity will be defined as a conceptualized object that is measurable in some way (Thompson & Carlson, 2017; Hackenberg et. al., 2021). A quantity defined in this way is a cognitive object that lives in the mind of the individual. From this definition, we define quantitative reasoning as the conceptualization of a certain situation in terms of quantities and the relations between them (Thompson & Carlson, 2017). A student's understanding of variable is affected by their quantitative reasoning because a variable is a type of quantity.

Defining Variable

Thompson and Carlson (2017) provide three ways in which students have been observed to understand variables. The first of these is the understanding of a variable as a fixed quantity with no variance. This will henceforward be referred to as *fixed understanding*.

Two other student understandings of variable Thompson and Carlson note are a) a value that changes based on context, and b) a quantity's value that varies within a given context. Castillo-Garsow and colleagues (2013) make this division more distinct by considering how a student imagines change. While thinking about a variable changing, students can construct chunks or units of values and then imagine change as being the shift from one chunk to another. When constructing these chunks, the student is not imagining variation or active change within the chunk. Rather, they focus on the discrete points on the edge of each constructed chunk. Castillo-Garsow and colleagues call this chunky thinking. In contrast, the ability to think about variation without chunks is called smooth thinking, because the values are seen as continually changing. For the purposes of this research, chunky and smooth thinking will be respectively referred to as *chunky understanding* and *complete understanding*.

Although these three understandings encapsulate most students' understanding of variables, the definitions tend to imply a variable does not vary with respect to anything else. However, when given solely one variable, most students insert time as a secondary variable the initial variable is changing with respect to. Thus, despite not all researchers having this perspective, all variation will be understood to be a form of covariation for the purposes of this research. Covariation is the concept that a quantity's value varies as another quantity varies (Thompson & Carlson, 2017). Ely and Adams (2012) include covariation as something that distinguishes a variable from an unknown or a placeholder. Note this idea of a varying quantity aligns closely with complete understanding of variable described above.

The full definition of variable for this research results from combining complete understanding of variable and covariation. We define a mathematical variable to be something that stands for a generic element of a large set of values that varies alongside another variable and takes on values as the other variable continually changes. As explained above, each participant's understanding of variables will be classified as either fixed, chunky, or complete.

Table 1: Initial Framework Created Prior to Data Collection

Category	Variable Understanding	Example
Fixed	A variable represents a single number. A variable's value does not change in a given context.	When illustrating a covariational relationship, the student draws a number line or plots a single point.
Chunky	A variable can represent multiple values. A variable's value can change in intervals or chunks.	When illustrating a covariation relationship, the student plots multiple points, then connects them.
Complete	A variable can represent multiple values. A variable's value can change in a smooth or continuous way.	When illustrating a covariational relationship, the student can sketch an accurate graph without plotting points.

Initial Framework

The threefold division of variable understanding (fixed, chunky, and complete) was used to construct a framework. The purpose of this framework was to classify students' understandings

of variable based on their approach to tasks. A simplified version of the initial framework developed from a review of literature can be found in Table 1.

Methods

Data Collection

Participants were middle school students from private schools in the Pacific Northwest United States. Three students were screened to assess their current understanding of variables and arithmetic reasoning (as part of a larger study). All participants had completed at least grade 6 math and at most pre-algebra. As a result, some mathematical topics covered in the interviews were novel for the students, providing the opportunity to see their initial thoughts and conceptions. Table 2 displays the results of the screening for each student. Note that all three students were placed at both chunky and complete understanding for solving. At this stage of the study, it was hypothesized that a student would have either fixed or not fixed variable understanding for solving.

Table 2: Screening Results for the Participating Students

Student	Solving	Graphing	Equation	Underlying Reasoning
S1	Chunky/Complete	Complete	Chunky	Chunky
S2	Chunky/Complete	Fixed	Fixed	Chunky
S3	Chunky/Complete	Complete	Fixed	Chunky

After the screening, all three students were invited and agreed to participate in a full set of task-based semi-structured clinical interviews (Clement, 2000). Interviews lasted between 30 and 60 minutes and involved the researchers and an individual student, totaling six interviews per student, with one task per interview. One researcher acted as the primary teacher-researcher, with the other as a research observer. Tasks were completed on a screen-recorded iPad, and three of the tasks involved an animation the students could interact with on the iPad. All interviews were also video- and audio-recorded to note students' gestures and explanations. Three types of tasks were used, focusing on either generating an equation, graphing a given equation, or numerical solving. For each type of task, there was a linear and non-linear relationship involved. The order in which the tasks were presented to the students alternated between the equation, graphing, and solving types, while also alternating between linear and non-linear (Table 3). It was structured in this way to minimize the impact of students' previous work on their approach to each new task.

Table 3: Task Descriptions

Task	Type	Animation	Equation given	Relation
T1	Equation	Yes	No	Linear
T2	Graphing	No	Yes	Quadratic
T3	Solving	No	No	Linear
T4	Equation	Yes	No	Exponential
T5	Graphing	No	Yes	Linear
T6	Solving	Yes	No	Exponential

Data Analysis

Several rounds of analysis were conducted in this study. Immediately following each interview, together the researchers noted their initial thoughts on what level of variable understanding the student displayed during the interview. These analyses served as a gauge for the researchers' understanding of the framework as they became exposed to more data. The primary researcher did small-scale data analysis between any two interviews for a student. During this analysis, little comparison was made between different tasks and students, primarily focusing on a student's work within one task.

After conducting all interviews, a large-scale retrospective analysis was performed by the primary researcher, focusing on one student at a time across all tasks. The recordings of each interview for a student were reviewed closely by noting indicators of specific levels of variable understanding. For example, say a student creates a graph by solving for two points, plotting them on a pair of axes, and then drawing a line to connect the points. By plotting the two points and then connecting them after, the student visually constructed a chunk and acknowledged intermediate values after constructing it. Based on the framework shown in Table 1, this would be an indicator of chunky variable understanding for graphing.

Once all the tasks for the student were fully reviewed, comparisons were made across all the tasks for each student, and an overall placement within the framework was selected. This process was done for all three students. When this was completed, the three students' attributed levels of variable understanding were compared to check for inconsistencies and to note any patterns across the tasks.

Results

Throughout data collection, the initial framework (Table 1) was revised to include more specific indicators in a student's numeric solving, graphing of relations, and use of equations. As this adaptation continued, the three levels of variable understanding became distinguished by two main features: determinate versus indeterminate, and not covariational versus covariational. This aligns with the definition of variable provided by Ely & Adams (2012). These features can be found in the simplified version of the full framework displayed in Tables 4-6. Because fixed understanding inherently lacks the conception of covariation, note that this framework cannot fully capture nuances within fixed understanding. Included below are the results of the large-scale retrospective analysis. The three participants will be referred to under the pseudonyms of Addie, Jim, and Duncan. The students were placed at either fixed, chunky, or complete variable understanding for solving, graphing, use of equations, and underlying reasoning.

Solving

Whenever a student was determining a particular numeric value based on other known values, this was considered numeric solving. Numeric solving did not align well with the three-fold division of variable understanding because it reduces a variable to a determinate value. For the purposes of this report, solving will not be discussed further.

Graphing

Behaviors surrounding the creation or interpretation of a graph were considered indicators of variable understanding while graphing (see Table 4). Figure 1 displays written work from each student when graphing in Task 4. In this task, students were given a scenario where a growing redwood tree starts as half of a foot tall and triples in height every two days. The students were asked to graph their understanding of the scenario.

Table 4: Framework for Graphing

Variable Understanding	Feature of Variable Understanding	Behavioral Indicators
Fixed	Determinate Not Covariational	A student plots one or two values (that are known) on either a number line or on a graph. The student treats each plotted value as an independent object.
Chunky	Determinate Covariational	A student plots multiple values that are known on a graph and then connects the points with a line or curve, acknowledging there are more points. When plotting values, they tend to be evenly spaced out. The student can articulate why the graph is shaped a certain way.
Complete	Indeterminate Covariational	A student is able to plot an accurate sketch of an entire relation without plotting more than one known (solved) value. The student can articulate why the graph is shaped a certain way.

Addie's graph Jim's graph Duncan's graph

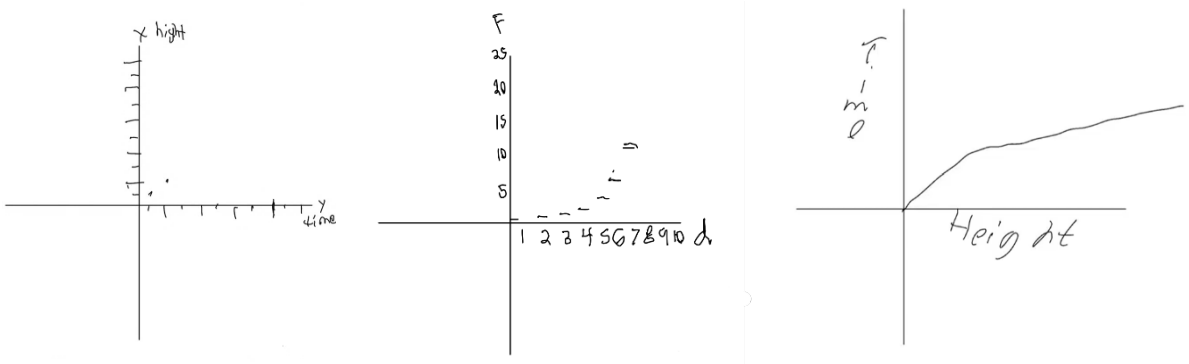

Figure 1: Student Graphs from Task 4

Addie demonstrated a combination of fixed and chunky variable understanding while graphing. When a task did not have time as a variable, she had a more fixed understanding. In these tasks, she initially only plotted one point whose value she had already solved for. After plotting more points, she saw each point as independent of the others, indicating limited covariational thinking. When a task did have time as a variable (the tasks with animations), she had a more chunky understanding. Her ability to sketch the graph's shape and describe its end behavior indicates that she thought about covariation in these contexts. However, she remained focused on the plotted points and previously solved values, treating the values as determinate.

Jim appeared more comfortable with graphs and demonstrated a chunky variable understanding while graphing. For four of the six tasks, he plotted points easily and without much thought, often referring to each point as an "answer," which is a determinate description. When asked about other points besides the ones he drew, he frequently talked about splitting sections with midpoints and forming additional chunks of equal size.

On the two tasks where an equation was given rather than student-generated, Duncan also displayed a chunky understanding. For these tasks, the graph was a display of "the answers" to the equation, just as Jim explained. However, unlike Jim, Duncan displayed a complete understanding of variable while graphing when an equation was *not* given (see Figure 1). He easily sketched a graph relating two quantities and did not focus on specific numbers, indicating he saw the variables as indeterminate. Once he created a graph, he clearly explained how it demonstrated the relation between multiple quantities, revealing his covariational thinking.

Equation

When a student was generating or interpreting an equation, the associated behaviors were considered indicators of variable understanding while using equations (see Table 5).

Table 5: Framework for Equation

Variable Understanding	Feature of Variable Understanding	Behavioral Indicators
Fixed	Determinate Not Covariational	A student interprets a variable in an equation as something that gives or stands for an "answer". When asked to create an equation, they construct an equality exclusively with numbers. When given an equation, a student cannot interpret how two variables are related.
Chunky	Determinate Covariational	A student interprets a variable in an equation as something that gives or stands for an "answer". When asked to create an equation, they construct an expression with at least one variable, treating some or all of them as placeholders for known values. When given an equation, a student can interpret how two variables are related.
Complete	Indeterminate Covariational	A student interprets an equation as something that relates two changing quantities. When asked to create an equation, they construct an expression with two or more variables. When given an equation, a student can interpret how two variables are related. A student can isolate a variable without dropping operations.

Across all tasks, Addie displayed a fixed understanding of variable when working with equations. Although she often verbally described a pattern between two quantities, she did not generalize it or create an equation. Any expression she created involved only numeric values or had a single unknown, which are very strong indicators for determinate thinking. When given an equation, she often had difficulties interpreting what it was representing, usually focusing on a few specific values for each variable involved. This shows she was unable to see the covariation in the equation.

In contrast, Jim and Duncan both displayed chunky understanding of variables when working with equations. Throughout all the tasks, they treated equations as a source of an answer or solution, reducing the variables to a determinate value. When given an equation, they articulated dependence and some covariation between the variables. However, their tendency to plug in numbers to "check" the equations is a counter-indicator of complete variable understanding. It is

evident that both Jim and Duncan tended to see variables in an equation as standing for either known numbers or solvable unknowns. An explicit instance of this is from Duncan when talking about the equation $\frac{1}{3}b = a^2$ in Task 2.

> Duncan: So this is kind of like a formula. So there's variables, and you can put in different numbers to make, to try and make it like, solvable. So, what I'm thinking, when I answered your question, was we like, put a number, for b.

This instance shows Duncan thinking of b and variables in general as standing for a number and not as something that varies. This is a very deterministic understanding of variable and is a strong counter-indicator of complete variable understanding when using equations.

Underlying Reasoning

An indicator was attributed to a student's underlying reasoning when the student explained their thinking in a more general sense or made connections between different parts of the task (such as connecting solved numeric values with a graph). A student's underlying reasoning impacts all aspects of the student's approach to a task and is not limited to either solving, graphing, or using equations. See Table 6 for a simplified version of this part of the framework.

Table 6: Framework for Underlying Reasoning

Variable Understanding	Feature of Variable Understanding	Behavioral Indicators
Fixed	Determinate Not Covariational	A student understands that a variable can stand for a known number or an unknown number that can be determined. When presented with two varying quantities, a student understands them to be unrelated to each other.
Chunky	Determinate Covariational	A student understands that a variable can stand for a known number or an unknown number that can be determined. A student understands that a variable is related to or dependent upon another variable.
Complete	Indeterminate Covariational	A student understands that a variable can stand for a generic element of a set and can change. A student understands that a variable is related to or dependent upon another variable.

Addie demonstrated a combination of fixed and chunky understanding of variable in her underlying reasoning. Throughout all the tasks, she was highly reliant on numbers and was unable to generalize patterns, indicating determinate thinking and counter-indicating complete variable understanding. In some instances, she struggled to conceptualize the idea of an unknown and articulate covariation between two related quantities, which are counter-indicators of chunky understanding. Below is an instance in Task 1 where Addie explains why there are other values for x and y that she did not graph. In this task, students were given the scenario of a steady-growing plant that starts as 3 inches tall and is 9 inches tall after three days. x and y were the respective symbols chosen by Addie to represent height and number of days.

> Researcher: How many different numbers could those [x and y have]?

Addie: Oh, a lot because you just keep going up... Um, yeah, you could go up forever because you'd just be adding two and adding one.

When referring to "adding two and adding one," Addie is referring to adding two to the height and one to the number of days, indicating she saw the two values as being separate. She gave similar explanations throughout this task. However, there were instances where she could articulate some covariation. These behaviors were not consistent enough across all tasks for her to be placed fully in fixed or chunky variable understanding.

Jim and Duncan were more consistent in their underlying reasoning throughout the tasks and both demonstrated a chunky understanding of variables. As mentioned previously, both were very focused on getting an "answer" or "solution" throughout the tasks. Although they occasionally talked abstractly, they ultimately always fell back onto a determinate understanding of variable when they encountered a contradiction. Duncan was more comfortable with the idea of covariation than Jim, allowing him to describe relations with accuracy and additional detail. However, similarly to Jim, Duncan consistently described and treated variables as something that you put a number in for, which is a good summary of chunky understanding of variable.

Discussion

Although this pilot study has a small sample size, comparing each student's variable understanding placement across the categories of graphing, equation, and underlying reasoning provides insight into what impacts a student's understanding of variable. It is notable that each student's variable understanding while graphing and using equations is not always the same. This implies a student who has a fuller understanding of variables in graphing may struggle to translate that understanding to using equations, and vice versa. Further, these observations indicate a student may be able to graph or use equations with variables well, while not truly understanding what a variable is. Since this observation has emerged in multiple studies (Carlson et al., 2002), it raises questions about what procedure might best gauge a student's variable understanding. Another noticeable pattern in the results is that, across all tasks, each student's variable understanding while using equations never exceeded their variable understanding in their underlying reasoning. This implies a student's comfortability with using equations may be a strong indicator of their true understanding of variable. It is worth noting that variable understanding while graphing did not display the same pattern.

During analysis, it was observed that the students' variable understanding shifted depending on the given task's attributes. For example, Addie displayed chunky understanding more when time was a variable, and Duncan displayed complete understanding more when not given an equation. Previous research has also shown that context can largely impact a student's interpretation of a scenario (Izsák, 2011). Although task attributes were not the primary focus of this study, these findings ought to be investigated in the future.

Considering the small number of participants in this pilot study, further research ought to be done regarding the relation of equations, graphing, and students' underlying reasoning with variables, as it may have implications on methods of assessment and tracking of student understanding. Additionally, the framework created in this study ought to be tested with a larger variety to students for further revisions.

Se presentan los resultados de un estudio cualitativo cuyo objetivo fue analizar cómo los futuros ingenieros descubren de manera guiada la influencia de los parámetros de la función cuadrática en su gráfica, a partir de la realización de actividades de una secuencia didáctica. El estudio está basado en la teoría de Educación Matemática Realista y contó con la participación de treinta estudiantes de diferentes carreras de Ingeniería. Se diseñaron tres actividades que están contextualizadas dentro de situaciones de la ingeniería Civil: canal hidráulico abierto, carga parabólica que recibe una liga en voladizo y puente Juscelino Kubitschek de Brasilia. Los resultados muestran cómo fue el proceso de matematización de los estudiantes al pasar por los cuatro niveles de comprensión: situacional, referencial, general y formal.

Palabras clave: Función cuadrática, Educación matemática realista, Ingeniería civil

Introducción

La función cuadrática es un tema importante en distintas áreas de la vida cotidiana, su aplicación es amplia en la mecánica, la economía, la ingeniería entre otros. Por ejemplo, en el caso de la Ingeniería Civil, los cálculos estructurales, cantidad de materiales y los costos de trabajo de puentes colgantes o canales de agua con frecuencia provienen de las parábolas que los representan. Sin embargo, varios investigadores mencionan que los alumnos tienen dificultades en el aprendizaje de este tema relacionadas con: articulación de registros gráficos y algebraicos (Endara, 2021); lenguaje algebraico (Villada, 2013); vinculación de la parábola con sus diferentes formas de notación: estándar, canónica y factorizada (Díaz et al., 2015; Villada, 2013).

Dado que la función cuadrática es un tema importante para distintas áreas, y existen dificultades de comprensión, es necesario cambiar la forma mecánica de enseñarla.

El propósito de esta contribución es presentar los resultados de una investigación desarrollada con alumnos de la carrera Ingeniería Civil, basada en Educación Matemática Realista (EMR), para quienes se desarrolló una secuencia didáctica que buscó propiciar el descubrimiento guiado de la influencia de los parámetros de la función cuadrática en la apertura de la parábola, su concavidad, desplazamientos verticales y horizontales.

La pregunta de investigación es ¿cómo evolucionan los niveles de comprensión—situacional, referencial, general y formal—durante el proceso de matematización del grupo de estudiantes al realizar las actividades de una secuencia didáctica basada en EMR del área de ingeniería en el marco de la función cuadrática?

Marco teórico

El estudio está basado en la teoría de la EMR propuesta por Freudental. Una de las principales ideas de la EMR es la matematización, la cuál puede ser de dos tipos: horizontal y vertical. En la matematización horizontal se traduce el problema del mundo real a un modelo matemático y se conectan los lenguajes natural, simbólico y formal. Y en la matematización vertical, el aprendizaje de los alumnos se traslada a lo largo del mundo simbólico. El proceso de matematización de un objeto matemático se desarrolla según cuatro niveles de comprensión: situacional, referencial, general y formal (Bressan et al., 2005).

El diseño de las actividades se da con base en seis principios: 1) de niveles, 2) de interacción, 3) de actividad, 4) de reinvención, 5) de interconexión, 6) de realidad (Bressan et al., 2005).

Metodología

La investigación fue de tipo cualitativa. Participaron treinta alumnos de las diferentes carreras de Ingeniería de una universidad pública. Sin embargo, sólo se describen los resultados de siete de ellos de Ingeniería Civil, por ser representativos de lo ocurrido en el aula.

Con base en los seis principios de diseño señalados por Bressan et al. (2005) se elaboraron tres actividades para promover la matematización. Debido a la extensión de esta contribución se presentan sólo los resultados de las dos primeras actividades.

La primera actividad está relacionada con un canal hidráulico abierto con una sección transversal de forma parabólica. Esta actividad se diseñó con el objetivo de que los alumnos descubrieran la influencia de los parámetros de la función cuadrática en la apertura de parábola, su concavidad y el desplazamiento vertical de la gráfica. En la segunda actividad se aborda una situación relacionada con una viga que se encuentra en cantiléver que recibe una carga distribuida a lo largo de este elemento. En la ingeniería civil, el ejemplo más sencillo de esta aplicación es un balcón. Esta segunda actividad se diseñó con el objetivo de que los estudiantes descubrieran cuáles parámetros determinaban los desplazamientos horizontales y verticales de la parábola. Y la tercera actividad está relacionada con el puente colgante Juscelino Kubitschek, en Brasilia. A partir de las características dadas en el problema, el estudiante debía proponer la función que describe a cada uno de los arcos.

Los instrumentos de recolección de datos fueron grabaciones de audio y hojas de trabajo. Estos se usaron para el análisis del proceso de matematización y para identificar la evolución de los niveles de comprensión—situacional, referencial, general y formal—alcanzados por los estudiantes.

Para el análisis del proceso de matematización se utilizaron los siguientes criterios de clasificación de los niveles de comprensión: 1) Nivel situacional. Los alumnos identifican visualmente una parábola en los objetos de la vida cotidiana. 2) Nivel referencial. Graficando las funciones cuadráticas con diferentes coeficientes propuestos por el docente, los alumnos comparan y analizan las gráficas de las funciones dadas. 3) Nivel general. Los alumnos proponen coeficientes de las funciones cuadráticas cuyas gráficas satisfacen características dadas. 4) Nivel formal. Los alumnos proponen las funciones cuadráticas que definen las parábolas, a partir de información obtenida de situaciones realistas.

Resultados

Enseguida se presenta el análisis de los resultados de la implementación de las dos actividades de la secuencia didáctica guiada, el proceso de matematización de los estudiantes y la evolución en sus niveles de comprensión.

La primera actividad

Los alumnos usando su intuición, y apoyados en las imágenes incluidas en la actividad (Figura 1), relacionaron el canal hidráulico con su modelo matemático $f(x) = ax^2$. La respuesta fue codificada como nivel situacional.

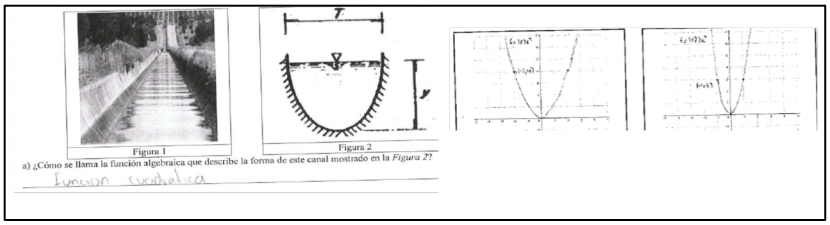

Figura 1: Respuesta de nivel situacional en la Actividad 1

Manipulando el valor de coeficiente a exploraron la influencia de éste en la apertura y concavidad de la gráfica, estas respuestas fueron codificadas como nivel referencial. Luego hicieron predicciones para determinar los valores del coeficiente a para los cuales la función $f(x) = ax^2$ se expande, se contrae o tiene cambio de la concavidad, estas respuestas fueron codificadas como nivel general de comprensión. En la Figura 2 se observa cómo los alumnos propusieron los parámetros para los cuales la gráfica tiene cambio de apertura y desplazamiento vertical indicado.

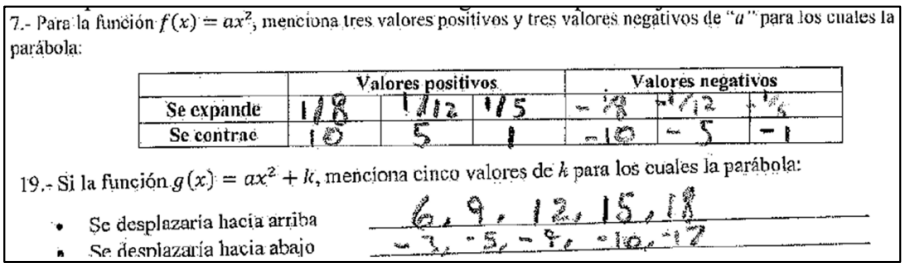

Figura 2: Respuesta de nivel general en la Actividad 1

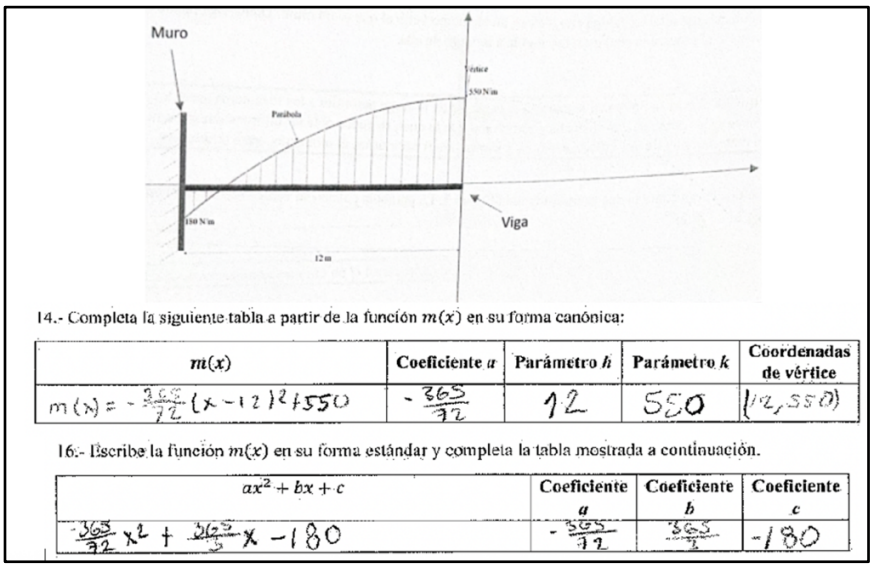

Finalmente, con base en los patrones identificados, establecieron que si el parámetro a pertenece a los intervalos $(-\infty, -1)$ o $(1, \infty)$ la apertura de la parábola es más ancha en comparación con los valores de a del intervalo $(-1,0) \cup (0,1)$; además, que la parábola cóncava hacia arriba para valores positivos de a y hacia abajo para los negativos. Estas respuestas fueron codificadas como nivel formal. Debido a que no hubo explicación previa por parte del profesor, el procedimiento de los alumnos se interpreta como descubrimiento guiado de estas características de la función.

Análogamente para la función de la forma $f(x) = ax^2 + k$, propuesta por el docente durante esta Actividad 1, descubrieron cómo los valores del coeficiente k, provocan desplazamientos verticales en la gráfica.

La segunda actividad

De manera similar a como se realizó en la primera actividad, en esta actividad relacionada con una viga en voladizo la cual recibe una carga parabólica, se introdujo el coeficiente h de la función cuadrática $f(x) = a(x - h)^2 + k$, el cual permite desplazar la parábola a la izquierda o

derecha. Los estudiantes graficaron funciones con diferentes valores del parámetro, analizaron, compararon y llegaron a conclusiones matemáticas. Finalmente, escribieron la función de acuerdo con las características de la carga parabólica propuesta en la Actividad 2 (Figura 3), además escribieron su respuesta en la forma canónica y estándar, lo que permitió a interpretar esta respuesta como nivel formal de comprensión.

14.- Completa la siguiente tabla a partir de la función $m(x)$ en su forma canónica:

$m(x)$	Coeficiente a	Parámetro h	Parámetro k	Coordenadas de vértice
$m(x) = -\frac{365}{72}(x-12)^2+550$	$-\frac{365}{72}$	12	550	(12, 550)

16.- Escribe la función $m(x)$ en su forma estándar y completa la tabla mostrada a continuación.

ax^2+bx+c	Coeficiente a	Coeficiente b	Coeficiente c
$\frac{365}{72}x^2+\frac{365}{3}x-180$	$-\frac{365}{72}$	$\frac{365}{3}$	-180

Figura 3: Respuesta de nivel formal en la Actividad 2

Reflexiones finales

Los resultados muestran que, mediante la realización de las actividades de la secuencia didáctica, los estudiantes analizaron el efecto de los valores de los parámetros de las funciones cuadráticas en las modificaciones de las gráficas, buscaron regularidades y comprendieron el comportamiento de la parábola producido al modificar los coeficientes de la misma. Además, exhibieron los cuatro niveles de comprensión (Bressan et al., 2005). Las preguntas incluidas en la secuencia didáctica ayudaron a los alumnos moverse a lo largo del mundo simbólico y desarrollar la matematización vertical. A su vez, el nuevo conocimiento les permitió generar predicciones y trasladarlas a las situaciones realistas propuestas, lo cual promovió la matematización horizontal.

La implementación de las actividades ofreció a los alumnos la oportunidad de reinventar matemáticas y alcanzar el nivel formal de acuerdo con el enfoque de EMR.

WHEN ALGEBRAIC ERRORS REFLECT WEAK PRACTICES RATHER THAN MISCONCEPTIONS: EVIDENCE FROM A CLINICAL STUDY

Derrick Kumi
Louisiana State University
dkumi1@lsu.edu

Keywords: Algebra and Algebraic Thinking, Learning Trajectories and Progressions, Mathematical Representations, Learning Theory

Students' difficulties with basic algebraic ideas, especially equality, relational reasoning, and variables, are well documented in the mathematics education research literature (Booth & Koedinger, 2008; Kieran, 1981; MacGregor & Stacey, 1997; Sfard, 1991; Sfard & Linchevski, 1994). These difficulties are often interpreted as misconceptions, such as treating the equal sign as an instruction to compute rather than as a statement of equivalence (Kieran, 1992; Knuth et al., 2005; Stephens et al., 2013) or interpreting letters as labels for objects rather than as symbols representing numerical quantities (Clement, 1982; Küchemann, 1978). In this study, however, closer analysis suggests that some *classic* algebraic errors reflect weak representational practices, even when the student demonstrates a robust semantic understanding of the underlying quantitative relationship. This poster presents episodes in which an incorrectly written expression co-occurred with evidence of a strong conceptual understanding, suggesting that some error patterns may be more productively explained as weaknesses in representational practice rather than evidence of conceptual misunderstanding.

Theoretical Framework

This study is situated within Piaget's (1964) theory of cognitive development, which conceptualizes learning as the reorganization of prior knowledge structures through processes of assimilation and accommodation.

Methods

A Grade 9 high school Algebra 1 student participated in three clinical teaching sessions designed to explore his current understanding of equality, variables, and linear relationships. As an interview method, clinical teaching is designed as a "powerful vehicle for entering the child's mind" (Ginsburg, 1997, p. ix) to uncover the underlying structures of thought that guide their interpretations, strategies, misconceptions, and emerging understandings.

Results and Implications

This clinical study challenges the assumption that algebraic errors necessarily indicate misconceptions. As illustrated in the Student–Professor task (see Figure 1), the student initially wrote $S \times 6 = P$, consistent with Clement's (1982) findings. However, after further engagement with the question, he quickly revised his response to $P \times 6 = S$, explaining that "however many professors there are, times 6 equals the [number] of students."

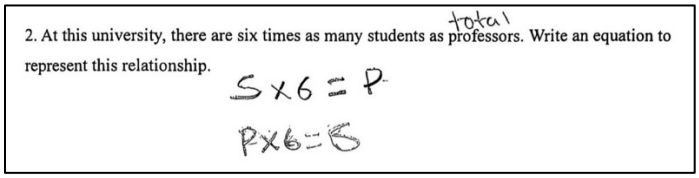

Figure 1: Evidence from the Student-Professor Task

Although the initial notation reflected a word-order matching strategy based on the linguistic structure of the statement, his explanation demonstrated a correct understanding of the multiplicative relationship. Thus, from a Piagetian perspective, the student's self-correction can be viewed as a process of cognitive reorganization in which existing arithmetic schemes are accommodated to support more advanced algebraic relationships. Similar patterns appeared in tasks involving equality and variables, where the student defined the equal sign operationally yet successfully interpreted non-canonical equations.

The findings from this study imply that instructional responses should distinguish between conceptual deficits and representational habits. Clinical teaching proved valuable in uncovering latent relational and structural understanding that may remain invisible in traditional assessments.

We amplify and extend a critique made by Leanne Betasamosake Simpson regarding a problematic similarity between the underlying logic of "abstraction" and the logics of extraction and removal that perpetuate many oppressive cultural phenomena. Locating ourselves at the site of the emergent definitions for Computational Thinking (CT), we similarly problematize the underlying logics of the common presentations of definitions for "abstraction" and "debugging." We offer alternative definitions for these and develop a refusal through diffractive inquiry involving narratives crafted with intention to amplify frequencies of relationality (and attenuate frequencies of coloniality). We briefly discuss implications for teaching.

Keywords: Debugging, Abstraction, Computational Thinking, Refusal

In this theoretical research report, we share some of our work in reimagining definitions for Computational Thinking (CT) that we intend to be less resonant with broader societal deficit narratives and colonial logics. Our goal is to develop attunement to ways in which computer science education can become more resonant with relationally-oriented ethico-onto-epistemologies (Chen, 2024; Paton & Sinclair, 2024). Using the examples of *abstraction* and *debugging*, we suggest that a relational understanding of CT concepts is possible—and may even better characterize the practices of computer scientists.

We position this article as diffractive inquiry (Barad, 2014; Murris & Bozalek, 2019) that investigates the resonances between two vignettes—which we have intentionally crafted to act as narratives (Rosiek & Snyder, 2020) that express our understanding of disciplinary relationships. Through this diffraction, we show how conventional definitions of debugging and abstraction in CT leave out relations among different kinds of beings and materials which are central to practices of disciplinary knowledge-creation.

Our goal with these relational definitions is to open space to account for the many dialogical and interconnected relationships in which disciplinary practices are embedded, and to move away from underlying colonial logics if possible. We motivate our inquiry with a discussion positioning iterative critical re-readings of disciplinary practices as necessary for enacting daily practice of justice, and subtle-yet-substantive acts of refusal to colonial logics. In our first vignette, we share an account of the many relationships that were inherent to Edward Lorenz and his research team during the early 1960s as they developed an abstract understanding of what is now known as "sensitivity to initial conditions." In our second vignette, we share an example of two teachers and a facilitator engaged in debugging within our designed learning environment.

This work emerged from an NSF grant through the STEM+C funding stream. This project consisted of the development and implementation of a professional learning approach that would

introduce teachers to CT, support their understanding of the mathematics and science they teach, and support the integration of CT into their math and science instruction.

Philosophical Perspective: Critical Re-readings and Refusals

Scholarship in STEM Education has increasingly begun to emphasize the importance of expecting and respecting multiple ways of knowing (Rosebery et al., 2010; Warren & Rosebery, 2011) and building dignity-oriented frameworks for theorizing learning and assessment (Kayumova et al., 2025; Kim & Saplan, 2024). One of the starting places for our research team has been the perspective that "theories and theoretical frameworks manifest onto-epistemological beliefs and identities and are therefore lenses through which we can see, analyze, and build new visions and justice-oriented worlds" (Kayumova & Dou, 2022, p. 1113).

Like many other scholars, our work involves "critical re-reading[s]" (Warren et al., 2020, p. 278) of STEM disciplines in order to look closer "at the ways disciplinary practices are narrated, framed, and enacted" (p. 279). The theoretical frameworks that we draw from position our ways of knowing and being as inherently and inevitably constrained and enabled by a material agency of inquiry and methodology (Garroutte & Westcott, 2013; Gouvea, 2024). Building from prior work, our perspective is the following:

> Recurring inequities, deficit-based discourses, and racialization of youth from nondominant communities are intertwined with larger knowledge systems in science education. These are rooted in (settler) colonial and racialized histories, which manifest themselves in our current thinking about what it means to be a science person and do science. (Kayumova & Dou, 2022, p. 1100)

We have thus been attempting to work towards "changing/ transforming science structures and norms by *forging new asset-based and relational justice oriented spaces*" (Kayumova & Dou, 2022, p. 1113).

A Critique and Form of Refusal

There is a critique regarding the concept of abstraction that we believe deserves to be more widely considered by the STEM Education community. Nishnaabeg scholar Leanne Betasamosake Simpson (2017) writes:

> Western thinkers get [abstraction] confused with extraction … Extraction is a cornerstone of capitalism, colonialism, and settler colonialism. It's stealing. It's taking something, whether it's a process, an object, a gift, or a person, out of the relationships that give it meaning, and placing it in a nonrelational context for the purposes of accumulation. (p. 201)

Since the concept of abstraction runs so deeply through STEM, we are alarmed by the idea that the logics that perpetuate epistemological erasure (Andreotti et al., 2011; Turkle & Papert, 1990) are legitimized (and even encouraged) by STEM disciplines when abstraction is conflated with extraction. Eve Tuck and K. Wayne Yang recommend (2014) that, "*Refusals* are needed to counter narratives and images arising (becoming-claims) in social science research that diminish personhood or sovereignty, or rehumiliate when circulated" (Tuck & Yang, 2014, p. 811, emphasis added). We question whether this resonance with colonial logics is necessary, if there could be another way to enact and embody the disciplinarity of STEM, and if it is possible to develop forms of refusal.

Simpson describes an Indigenous approach towards *abstraction* as a practice of "shifting the relationality to change meaning or to illuminate a different meaning" (Simpson, 2017, p. 201).

We notice that this counter-framing of abstraction still describes disciplinary practices of Computer Science and Mathematics.

We are thus interested to find similar counter-framings for other CT concepts. However, we recognize a tension of hybridizing knowledges in ways that inevitably lead to further assimilation and erasure (Ahmed, 2016). We tentatively (Ahenakew, 2016) present our work with a firm disclaimer that our proposed counter-definitions may still be problematic, and may still be much too subtle. Additionally, our goal of creating alternative definitions should *not* be thought of as a "replacement" of dominant definitions. In fact, functionally "equivalent" definitions would surely reproduce equivalent problematic resonances and impacts of harm. We instead share our theoretical ideas to highlight the importance of *intentionality* in our enactments of STEM—so that we may pay better attention to what they help re-produce. We see Simpson's reformulation of the concept of abstraction as a window to an alternative and incommensurable way of being "abstract." Looking through this window, the previous problematic resonances with colonial logics do not appear to be necessary to tolerate.

Motivation

Crucially, our search for refusal is motivated by noticing a reciprocal implication of the critique: If daily enactments of disciplinary practices can potentially resonate with deficit discourses and colonial logics, and contribute to impacts of harm; then attuned counter-enactments of disciplinary practices can contribute to emergent impacts of care, and daily practices of justice (Everett, 2020). That is, if subtle disciplinary discourses can potentially contribute to forms of harm, then subtle counter-framings should also be theoretically capable of contributing to forms of care and repair.

Gloria Ladson-Billings (2015) argues that we need to attend to injustice by shifting from "justice as theory to justice as practice." Further, Sakeena Everett (2020) argues that "we need to adopt a paradigm that understands *justice as a daily practice*" (p. 102). Restorative justice practices begin with careful listening for impacts and implications—similar to the daily practices of reflective scientists and attentive teachers. Drawing from Ladson-Billings (2015) and Winn (2018), Everett (2020) describes justice as praxis as "a *daily theory-informed reflective practice*—a theoretical and pedagogical paradigm committed to seeing the full humanity of others and making things right" (p. 102).

Given any curriculum or lesson plan, a teacher inevitably shapes how students are enabled or constrained to engage with disciplinary concepts. Expert teachers are expertly attuned to noticing and counteracting subtle ways that the learning environment might be reinforcing narratives that harm students (such as, discourses of gender or cultural deficits). Our motivation to problematize and reimagine the impact of CT concepts is strengthened by the implication that it is possible to enact at least some changes—even if a teacher cannot entirely change their curriculum. Our reimagined definition of debugging and Simpson's formulation of abstraction can be enacted as themes that teachers emphasize or simply ideas that teachers begin to internalize or think-with for their own practice.

Implications of Dominant Framings of Abstraction and Debugging

In this section we elaborate on some of the hidden implications of dominant framings of abstraction and debugging in CT. We hope that by bringing these entailments to the fore, the potential harm of these definitions becomes more tangible.

Abstraction as "Decontextualizing and Manipulating Symbols"

We notice that the dominant framing for what it means to practice "abstraction" in mathematics curricula (e.g., Common Core State Standards for Mathematics, 2010) and

Computer Science (Lafuente Martínez et al., 2022; Rijke et al., 2018) often implies that disciplinary expertise entails becoming an arbiter of what is important and what is discardable in a process of decontextualization. The Standards for Mathematical Practice, for example, describe reasoning abstractly and quantitatively in the following way:

> Mathematically proficient students make sense of quantities and their relationships in problem situations. They bring two complementary abilities to bear on problems involving quantitative relationships: the ability to *decontextualize—to abstract* a given situation and represent it symbolically and manipulate the representing symbols as if they have a life of their own, *without necessarily attending to their referents*—and the ability to contextualize, to pause as needed during the manipulation process in order to probe into the referents for the symbols involved. (Common Core State Standards for Mathematics, 2010)

Despite valuing reflective questioning to some degree, this framing implicitly (but undoubtedly) positions disciplinary proficiency as proficiency with deciding when it is "necessary" or not to remove the context from a given situation and extract symbols to "manipulate." Notice some subtle implications of the previous description: (a) The act of *decontextualizing* is framed as an *ability* that one can simply be either good or bad at. (b) There is no distinction made between *discarding* context, *responsibly choosing relevant* contexts, and *failing to notice* contexts. And (c) in choosing/creating representations, one unavoidably *stops* seeing certain context, which turns the question of *who* stops seeing *what* context *crucial* for abstraction practices—a question absent from this definition.

Debugging as "Finding and Fixing Bugs"

"Debugging" is a key component of CT, and is conventionally defined as a systematic approach to finding and fixing bugs in the system (Grover & Pea, 2013; Weintrop et al., 2016; Wing, 2006). We can again attune to subtle yet real entailments of this definition. This framing of debugging implies that: (1) There are *intrinsic* bugs—intrinsic wrong things—in a system that one needs to find and fix; (2) "becoming a computational thinker" entails being good at finding what's "wrong;" and (3) there is the hidden assumption that we all have the same understanding of what "the system" is supposed to *do* and of what it means to "fix" bugs in the system.

The Implied-Default Relational Ethics

We are sympathetic to the reaction that this might not initially seem very alarming. But we feel an urgency to take seriously the potential implication that simply to become enculturated with the logics that perpetuate the STEM disciplines may implicitly *require* you to become comfortable absolving colonial logics that perpetuate harm.

Scholarship emphasizing the relational aspects of CT (Dickes & Farris, 2019; Sengupta et al., 2018; Silvis et al., 2022; Sohr et al., 2023) helps us to notice the following in discourses of CT and other STEM disciplines: The *absence* of a central tenant of care within current discourses of computing and mathematics *simultaneously mobilizes* a complementary disciplinary ethic in STEM disciplines. Maintaining a distance between discourses of STEM and discourses of care inherently establishes a default ethic of ambivalence to relational impacts such as harm or care. Without ethics of relational care built into the definitions of what it means to practice disciplinarity, ignorance and ambivalence are instead left behind as a default disciplinary ethics.

To express how one can infuse relations of care in abstraction and debugging practices, we now shift the relationality within our narration of two vignettes that involve these CT practices. This shift shows that it is possible to construct disciplinary ethics of care that inhere in CT practices.

Vignette A: Edward Lorenz Engaged in a Moment of Disciplinary Listening

This vignette is an account of the early mathematical development of Chaos Theory. Specifically, Edward Lorenz can be understood to be in many different material-dialogic (Hetherington et al., 2018) conversations, and listening to many more-than-human agents (Krishnamoorthy, 2023). For Lorenz and his team of researchers (Sokol, 2019), the development of the abstract property of "sensitivity to initial conditions" centrally involved paying close attention to the subtleties of relationships between the particular computing machine, the system of differential equations, and human desires to better understand emerging relationships. Before 1961, Edward Lorenz was using a system of 12 differential equations and an early computer to numerically simulate weather patterns. He describes deciding to reexamine the machine's output:

> I stopped the computer, typed in a line of numbers that it had printed out a while earlier, and set it running again. I went down the hall for a cup of coffee and returned after about an hour, during which time the computer had simulated about two months of weather. (1993, p. 134)

The new numbers were wildly different from the old numbers, and Lorenz initially suspected a faulty vacuum tube or some problem with the machine he was using (Lorenz, 1963a). Inquiring further, Lorenz (1993) found that, "the new values at first repeated the old ones, but soon afterward … more or less steadily doubled in size every four days [of simulated data] or so, until all resemblance with the original output disappeared" (p. 134). The computer used six digits of precision, but its readout only showed three. So his re-entry of data from the readout introduced a small perturbation to the trajectory of the simulation. Lorenz realized that he was seeing the round-off errors steadily being amplified and creating significantly new patterns of behavior.

This property of "sensitivity to initial conditions" is now understood to be quite strange: Imagine the dynamics of dust blowing around the inside of a box with wind on the inside—the dust moves but it stays in the box. It is possible to have a bounded system of differential equations (describing the wind and dynamics of the dust) such that—no matter how close two pieces of dust started next to each other—it would be impossible to guarantee that those two pieces would remain nearby to each other in a way that you could estimate. This is strange. If the trajectory of a piece of dust corresponded to the time-evolution of a weather system, for instance, you might expect that modeling the behavior of a "nearby" estimate would help you make a weather prediction. You might expect that you could make a prediction for any later time if your estimate is accurate enough. But with a system with this chaotic property of sensitivity to initial conditions, no such estimates are possible.

Lorenz noticed this phenomenon by attuning to the difference between the original numerical predictions and the predictions after his accidental perturbation (chopping the tail of the decimal expansion). In a way, the computer was speaking back to the research team in a new and unexpected way, and they chose to listen and engage. Lorenz then followed a suggestion from Barry Saltzman to study a simplified system (Lorenz, 1963a) with only three nonlinear differential equations that seemed to exhibit a similar sensitivity to initial conditions. Lorenz's choice of a system of three equations could only possibly involve attempting to capture some essence of behavior that he *felt* with the previous twelve. Remember: this property was not yet formalized, and the field of Chaos Theory had not yet been started. He had no framework to be sure that it would exhibit the same abstract property.

Lorenz's process of choosing a system of three equations from the previous twelve was a process of intentional listening to different agents and attempting to understand the interconnected relationships. Their abstraction of the concept of "sensitivity to initial conditions"

could not possibly be a removal of context because his team was in the very middle of *creating* that particular ontological innovation (diSessa & Cobb, 2004).

By 1975, this new emergent middle ground between order and randomness was coined chaos (Li & Yorke, 1975). Writing in Transactions of the New York Academy of Sciences, Lorenz (1963b) ended his conference paper humorously with this dry paragraph:

> When the instability of a uniform flow with respect to infinitesimal perturbations was first suggested as an explanation for the presence of cyclones and anticyclones in the atmosphere, the idea was not universally accepted. One meteorologist remarked that if the theory were correct, one flap of a sea gull's wings would be enough to alter the course of the weather forever. The controversy has not yet been settled, but the most recent evidence seems to favor the sea gulls. (p. 431)

Eventually, this metaphor evolved into what is now called the butterfly effect. Lorenz's presentation at the 139th meeting for the American Association for the Advancement of Science (1972) was famously titled, "Predictability; Does the Flap of a Butterfly's Wings in Brazil Set Off a Tornado in Texas?"

Lorenz could not have done this computational modeling work without the computer present. But his exploration depended on being able to hear what his simulation communicated back to him. And in this case, the output of the simulated computational model was one of the voices that directed the conversation into new and generative territory. A Bakhtinian (1986) analysis of what Lorenz "listened" to in this interaction might at the very least consider the computer's responses as a kind of distorted echo of his own programming. With a perspective of the social and distributed aspects of that cognitive system (Hutchins, 1995), we might additionally conceptualize the computer as a refined artifact of multiple human conversations and understanding. The computer was carefully designed, built, tested, adjusted, and shipped to "speak" in a particular way; and, in this sense, the computer represents the cultivated outcome of many accumulated voices in material-discursive (Barad, 2003) conversations.

When it happened that the computer spoke to Lorenz in a way that he did not expect, its voice emanated from a sedimentation of culture—much as the way our real voices (and all utterances) come from internal echoes of cultural practices within our own minds (Wertsch, 1991). So Lorenz's scientific contributions emerged as the product of many relationships and conversations with human and more-than-human agents. He attuned his listening (with the help of the computer) to what different equations and systems of equations would say to him as he attempted to deeply understand these many relationships.

But Lorenz's relationships with the computer and systems of equations were not the only disciplinary relationship supporting this work. Margaret Hamilton and Ellen Fetter worked (consecutively) as technical assistants for Lorenz, and their work would be worthy of coauthorship by today's contemporary publication norms (Sokol, 2019). Writing for Quanta Magazine, Joshua Sokol interviewed both Hamilton and Fetter to revisibilize their entanglement with Lorenz's work. Sokol (2019) quotes Hamilton as saying, "He loved that computer. And he made me feel the same way about it." Sokol relays anecdotes from Hamilton:

> She recalls being out at a party at three or four a.m., realizing that the LGP-30 wasn't set to produce results by the next morning, and rushing over with a few friends to start it up. Another time, frustrated by all the things that had to be done to make another run after fixing an error, she devised a way to bypass the computer's clunky debugging process. To Lorenz's delight, Hamilton would take the paper tape that fed the machine, roll it out the length of the

hallway, and edit the binary code with a sharp pencil. "I'd poke holes for ones, and I'd cover up with Scotch tape the others," she said. "He just got a kick out of it."

Lorenz first mentioned the sensitivity to initial conditions of their weather model at a conference talk in November of 1960—meaning that Hamilton would have been running the calculations where this piece of chaos theory was first noticed. Hamilton moved to another project in the summer of 1961, and trained Fetter as her replacement. Margaret Hamilton eventually led the team for the onboard flight software for the Apollo project and also the team that wrote software for the first US space station (Sokol, 2019). Hamilton is very highly regarded in the history of computing, and she is credited with coining the term "software engineering."

Vignette B: Debugging within a Professional Learning Environment for Teachers

Our own research project involved developing and implementing a professional development program for teachers to both learn about computational thinking and develop their own lessons incorporating computational thinking practices into their curriculum. We videorecorded approximately 90 hours of professional development over two separate year-long sequences. Each year, participating teachers attended a week-long workshop over the summer, monthly professional development sessions during the school year, and monthly one-on-one coaching sessions with the workshop instructors with feedback on their lesson planning.

Debugging is an underrepresented topic in K-12 classrooms (Kafai et al., 2020), and there is a gap in the literature examining exactly how debugging emerges for K-12 teachers and students. So one aspect of our data analysis was to search for episodes of debugging that happened during the professional development sessions. We identified such a moment of debugging during one of the monthly professional development sessions, and we noticed that it was novel in the sense that the episode did not quite fit the standard narrative of debugging. Through repeated video review and event reconstruction consistent with Interaction Analysis (Jordan & Henderson, 1995), we developed transcriptions and analytical memos to describe the interactions that inhered in the teachers' and instructor's debugging process.

Two of our teachers (Mary and Julie) and the workshop instructor (Jarod) found themselves debugging a system involving a small mobile robot programmed in a block-based coding environment. The robot has a sensor on its "chest" that uses a calibrated frequency of light to measure the distance to an object in front of it. The group was attempting to program this robot so that it would check whether something was blocking its way, and then either continue ahead or turn around and move in the opposite direction. Julie's code was not making the robot behave how they wanted. It continued ahead without turning around when it should have. Jarod then changed the code. The robot's behavior running the code was to turn around without continuing ahead when it should. The group questioned whether having the robot on the floor was affecting the response of the sensor and causing the robot to behave how they observed. The group then put the robot on the table and ran the code while Jarod held his arms in front of the sensor. The robot continued ahead into Jarod's arms. But the same code then caused the robot to repeatedly turn around when nothing was in front of the sensor. Jarod questioned whether his previous understanding of the code syntax was correct, and the group changed the code back to Julie's original version. The robot then responded in the way they had intended to program it.

Developing a Relational Definition of Debugging

Our teachers and facilitator wanted the robot to do something, and at first the robot was not doing it. They spent time trying to understand and adjust. And then the robot did what they had

hoped. So, we can confidently say that whatever happened in their time understanding and adjusting is fair to characterize as "debugging." However, we find it interesting that this debugging event is difficult to reconcile as a systematic search for errors. Instead, the group examined the ways that all the elements of the system were coming together. In this example, the "debugging" done by the participants involved *coming to understand the nuances of the relationships among elements of the system.*

We are resistant to identify any one "bug" that they needed to identify and fix. Julie's original code was logically correct, and her understanding of the conditional statements was correct. The sensor was not broken; it was working correctly—the materiality of the sensor just is the way that it is. Jarod's temporary understanding of the syntax of the coding environment could be considered wrong. But that error did not cause the problem, so we are resistant to calling that "the bug." Their reasonable expectations for how the sensor would react with the robot on the floor could possibly be identified as the "bug." But we are resistant to characterizing their debugging process as systematically "fixing" that expectation.

To understand how the sensor, code, and surface were interacting, the group engaged in a creative process of imagining what could be happening to the agents in the system. We notice that this framing of debugging is much more relational, and less resonant with deficit-discourses problematized earlier.

Debugging can then be understood as a relational activity of listening closely to many interconnected relationships and coming to understand relationships in the system in richer ways.

Describing debugging in this way—as a process of paying close attention in order to understand the subtle ways that many things interrelate and influence each other—fits this scenario just as well as other dominant narratives of debugging.

With respect to Vignette A, consider the initial moment of confusion that Lorenz mentions as the genesis of their scientific journey. Lorenz and Hamilton had programmed the computer to do something, and at first, it was not doing it. They then certainly spent time systematically trying to understand the problem. Lorenz had said that the first assumption that came to mind to explain the errors was a faulty vacuum tube (a consumable part of early computing technology). Although finicky by today's standards, there was no bug or faulty tube inside the machine.

Like the teachers, before Lorenz and Hamilton could get the computer to respond in a way they expected, they needed to adjust both their expectations as well as their code. And they needed to understand how all elements of the system came together. It seems fair to call this process debugging since the computer was not acting as they expected, and they went on a systematic journey to uncover the problem. But this journey does not easily fit the dominant definition of debugging: (1) there were no intrinsic errors to be found and fix, and even more, (2) what the system was "supposed to do" had to be re-imagined. We are dissatisfied to call this a failed or abandoned search for errors because their search produced a whole new field of research, a fantastic story of a mathematical eureka moment, and a result so culturally impactful as to reach far beyond mathematics into the zeitgeist for decades.

So on one hand, this event for Lorenz and Hamilton initiated some kind of systematic search for errors. Yet on the other hand, it did not terminate for years and did not succeed in finding or removing any errors. And the event involving the teachers and facilitator in our study also involved a search for errors in the system that included their code, the environment, and their thinking. Both events involved trying to debug a system so that it behaves as expected, neither event fits the dominant definition of debugging, and both events can be characterized according to our relational definition.

In this article, we chose to look deeply at the relationality and potential relationality of debugging and abstraction because we envision relational redefinitions such as these ones to hold potential for teachers to enact daily theory-informed reflective practices of justice in their own contexts and ways, no matter what curriculum they find themselves in the middle of.

DISRUPTING DEFICIT-FRAMED INSTRUCTIONAL PRACTICES FOR MULTILINGUAL LEARNERS IN MATH: TENSIONS AND OPPORTUNITIES

Anna Gustaveson

dicross@unc.edu

In this study, we engaged 24 elementary preservice teachers (PSTs) in a series of discussions aimed at addressing common deficit framings of multilingual learners and research-practice implementation gaps. Through analysis of these discussions, we found that PSTs problematized deficit-framed instruction practices while also using deficit framings of MLLs themselves. We also noted areas of tension for PSTs when they considered engaging MLLs using asset-framed instructional practices.

Keywords: Preservice Teacher Education; Equity, Inclusion, and Diversity

Introduction

Deficit narratives about multilingual learners' (MLLs') ability to engage in rich mathematics are all too common in K-12 schools (de Araujo, et al., 2016; Shapiro, 2014), with statements like "She does not have the language skills to do word problems" (Gustaveson & Cross Francis, 2025). These discourses promote linguistic hegemony by prioritizing English development and positioning multilingualism as a deficit (Wiley & Lukes, 1996; Endo & Reece-Miller, 2010) while obscuring the repertoire of cultural and linguistic assets MLLs already have (Yosso, 2005). Meanwhile, teachers' limited access to research findings (Sato & Loewen, 2019) creates a persistent gap in the implementation of evidence-based practices in classrooms (Korthagen, 2017). This is specifically true for implementation of rich practices when working with MLLs. For example, preservice teachers (PSTs) have been found to lower the cognitive demand of math tasks as a practice for supporting MLLs (de Araujo, et al., 2021). Some MLLs receive individualized instruction through specialized programs where teachers are trained in evidence-based practices, but the separate instruction and labeling of students can lead to stigmas from their general education classroom teacher (Kanno, et al., 2024). Therefore, creating opportunities for teachers to learn evidence-based approaches for working with MLLs in the general education classroom is needed to close the implementation gap.

These challenges together call for more efforts in teacher education to: (i) develop math teachers' awareness of deficit narratives about MLLs, and (ii) prepare teachers to better enact evidence-based practices with MLLs in mathematics. In our study, we engaged 24 elementary PSTs enrolled in a math methods course in three discussions to support these aims. In the first discussion, PSTs unpacked a sample deficit narrative about MLLs; in the second, they addressed lingering questions from the first; and in the third, they considered research-based practices for working with MLLs. Using the transcripts from the three discussions, we explored the following research questions: What did PSTs name as potential asset-oriented practices for working with MLLs and language development in math? What tensions around practices for working with MLLs and language development in math came up in the discussions?

Conceptual Framing

Shifting to an Asset Frame

Since the inception of public school, deficit labels like "slower learner" and "limited English proficiency" have been used to describe students' competence in math, focusing on what students lack and describing students as problems to be fixed (Deschenes et al., 2001). These labels reflect broader systemic narratives, or master narratives, that view ability as a fixed trait (Larina & Markina, 2020; Dweck, 2006) and privilege the use of the dominant language in schools (i.e., English in the United States; Wiley, 2014). Deficit systemic narratives can also serve to blame students' families and culture for students' success outcomes in math (e.g., standardized test scores), rather than looking at the role students' access to opportunity plays in those outcomes (Ladson-Billings, 2007; Milner, 2012). Because of the prevalence of these systemic narratives, deficit discourses are common in schools and in research (Adiredja & Louie, 2020). For example, Jones & Marchant (2021) found that the majority of research in mathematics education describing work with students from la Raza (i.e., Hispanic, Latin@) used deficit frames to contextualize their studies. Therefore, even if teachers have access to research about what the field puts forward as best practices, they may still be framed in deficit ways. These deficit frames have tangible negative impacts on MLLs. First, deficit ideas about multilingualism influence the types of opportunities MLLs receive to learn math (de Araujo et al., 2021). Second, students are often aware of their teachers' expectations for them which can influence their feelings of belonging in the classroom space (Shapiro, 2014).

To counter deficit frames, scholars have called for the use of asset frames that focus on students' strengths (Gustaveson & Cross Francis, 2025; López, 2023). This framing acknowledges students' funds of knowledge (Moll, et al., 1992) and community cultural and linguistic capital (Yosso, 2005), in order to view multilingualism as an asset rather than a problem to be solved. Additionally, asset-oriented frameworks embrace growth models of competence, understanding ability as ever evolving through experience (Dweck, 2006). An important part of asset-framing is for teachers to consider how to create opportunities for MLLs that help them to grow in their mathematical thinking by building from students' existing knowledge. However, shifting toward an asset frame is not without its complexities or pitfalls. Scholars warn against superficial views of culture and language, that treat all students from a group as the same and fail to engage in systemic change (Ladson-Billings, 2014). For example, overemphasizing growth models of competence without improving students' access to opportunity can slip into grit ideologies which can unfairly blame students' effort instead of addressing systemic barriers (Golden, 2017; Gorski, 2019). Additionally, an overfocus on the assets of students' home language without providing opportunities for English development could leave students underprepared for context-based math problems in English-only contexts. Therefore, it is important to consider possible tensions as teachers engage in taking on asset framings of student competence.

Research as a Resource for Supporting Instruction

Drawing strong connections between theory and practice has been a focus of education researchers for decades (e.g., Darling-Hammond et al., 2020; Dewey, 1904). These connections have been intensified by the growing body of scientific inquiries into teaching and learning, as well as their significant impact on educational practice and policy (Darling-Hammond et al., 2020; McKenney, 2018). In this regard, educational research findings have become a significant resource to support teachers in making evidence-based instructional decisions (Willingham, 2017; Yu & Cross Francis, 2025). The importance of using research findings as a resource for

guiding teachers' instruction has both theoretical and empirical foundations. In his original work on teacher knowledge, Shulman (1987) foregrounded educational theory and research as one of the four major sources for advancing teachers' knowledge and supporting the implementation of evidence-based practices. Specifically, Shulman highlighted the unique value of educational scholarship in enriching teachers' visions of what constitutes good teaching or what students can achieve given the most appropriate intervention and scaffolding. Empirical studies suggest that such visions, enhanced by educational scholarship, can further shape how teachers understand the goal of teaching specific content, thereby influencing how they design, implement, and reflect on the lesson (Bransford et al., 2005; Lohse-Bossenz et al., 2015; Yu et al., 2025).

The unique value of educational research becomes more evident in supporting PSTs in developing knowledge about practices that have not been well established in classrooms. Studies have shown that, despite methods classes shifting their beliefs, PSTs still struggle to align their practice with those beliefs (e.g., Philipp, 2007). These struggles may stem from a limited view of instruction within established classroom routines (Cheng et al., 2012) or difficulties in realizing their beliefs in specific contexts (Yu & Cross Francis, 2025). In terms of teaching multilingual learners in math, challenges do not only exist in changing teachers' perceptions of MLLs (e.g., deficit-oriented to asset-oriented), but also in enacting practices proven to be effective in providing equitable learning opportunities for MLLs. Educational researchers have engaged in efforts to dismantle the myth that mathematics is free from language (e.g., the word problem) (e.g., Arizmendi et al., 2021). Additionally, there has been an empirical focus on identifying practices that support MLLs in learning math; practices that have been verified as effective in classrooms (e.g., using multiple representations to address linguistic diversity) (Sharma & Sharma, 2023). This information can expose PSTs to evidence-based approaches that challenge and complement the current practices they witnessed in their field placements.

Methods

Participants and Context

This study is situated in a graduate-level mathematics methods course for elementary PSTs. The major goals of this class are to build PSTs' productive beliefs about mathematics teaching and learning, and to equip them with tools and knowledge to teach in equitable ways. While enrolled in the methods class, PSTs also visited elementary field placement classrooms weekly. Participants in this study were recruited in a voluntary manner which led to a total of 24 PSTs.

Supporting MLLs was a major topic in the methods class, as the current practices for teaching MLLs in PSTs' field placements were not perceived as asset oriented. Two teaching assistants in the methods class specifically designed discussions to (1) support PSTs to combat the existing deficit-oriented framing as well as (2) build their goals and knowledge for supporting MLLs in evidence-based ways. The first, narrative discussion asked PSTs to unpack a hypothetical teacher statement related to MLLs: "*She doesn't have the language skills to do word problems. I'm giving her easier work that she already knows how to do, so she feels successful*." They were prompted to describe the underlying assumptions, potential impact, and language practices they could use in their own classrooms (Gustaveson & Cross Francis, 2025). The second narrative discussion was designed around their follow-up questions to the first discussion, such as "how do we make language support more humanizing?" In the third discussion on related research, we shared a summary of research findings on evidence-based practices for MLLs. PSTs were prompted to read the summary and reflect on how the findings resonated with their current experiences as student teachers in field placements and how they might inform their

future teaching. Table 1 presents the artifacts presented to PSTs, along with the discussion questions that guided conversations.

Table 1: Discussion Artifacts and Discussion Questions

Discussion Artifact	Discussion Questions
Deficit Narrative A common deficit narrative: "She doesn't have the language skills to do word problems. I'm giving her easier work that she already knows how to do, so she feels successful."	What are the potential assumptions being made in this statement? What might be the impact of this statement? What implications does this discussion have for your own teaching practice?
Lingering Questions A list of questions PSTs brainstormed: What is the context behind "language skills"? What about students who don't have any home language? If we ask another student to help, how do we ensure the student helping does more "guiding" rather than "doing" the activity for the other student? How can it be more humanizing/bring in language assets?	What lingering questions do you have from the deficit narrative discussion? What are your thoughts on these questions?
Research-Based Practices A short synthesis passage on research-based practices: "Classrooms in US public schools have experienced an increase in language diversity in the past 20 years. In 2017 Fall, English Language Learners (ELL) made up 10.1% of the school-age population, with nearly 75% of these children having Spanish as their first language (U.S. Department of Education, 2020). It is commonly thought that math is free from language, however, additional vocabulary learning is required for learners to become proficient with the language of math. However, this can be minimal. For example, "plus," "sum," "add," "altogether," "increase," "in all," and "more than" could all be interchangeably used for one single concept "+" (Veel, 1999; Wolf & Leon, 2009). This common belief may lead to language skills being confounded with students' math abilities, especially for math word problems where language processing places additional cognitive demands on students (Arizmendi et al., 2021). Alt et al. (2014) found that when language–heavy math tasks were reduced in language load, ELLs performed as well as their monolingual peers. Sharma & Sharma (2023) identified the four successful interventions for ELLs in multilingual mathematics classrooms, including dual language programs (e.g., incorporating marginalized cultural content and heritage language in classroom mainstream), curriculum integration (e.g., asking kids to create, define, and reflect on integers using the number line), teacher professional development (e.g., teachers learning and using research to challenge common myths like "math person" and developing growth mindset), and cognitively focused interventions (e.g., asking students to "think aloud" while solving a problem and building their skills in monitoring their thinking)."	Are there any interventions differentiated to the needs of multilingual learners in your placement classrooms? How are they similar or different from any of the research findings? Reflect on the interventions you identified. How well do you think it works in supporting multilingual learners' learning? Think ahead, what would you like to try in your future classrooms with multilingual learners?

Data and Analysis

Data included transcripts of each of the three discussions at both the whole-group and small-group levels (~4 students). All three activities include the whole-group discussion transcript, while only the Narrative Talk discussion includes small-group discussion transcripts. To answer

research question one, we explored the kinds of practices PSTs hope to use in their classrooms and how they frame them. We began by highlighting any instructional practices that PSTs named in relation to incorporating language development in math in the transcripts for the 3 discussions. We considered instructional practices to be the concrete actions teachers take in the classroom as part of their daily teaching. For example, PSTs described "giving students a translated copy of the material," an action they would take in their teaching to specifically support MLLs' language comprehension. We then considered how PSTs framed these practices when bringing them up in discussion. We initially planned to label the practices PSTs suggested as asset-oriented, deficit-oriented, or unclear/neutral. As we attempted to label the list of highlighted instructional practices, we noticed that PSTs sometimes talked about practices of other teachers, attempting to problematize them rather than suggest their use. We decide to label the practices as: "suggesting practices (asset frame)," "suggesting practices (deficit frame)," "suggesting practices (neutral/unclear frame)," and "problematizing practices" (see Table 2 for code descriptions). In our findings, we describe the types of practices PSTs mentioned and look at the percentage of practices that fall under these four labels.

Table 2: Codebook

Code	Description
Suggesting practices	PSTs suggest a practice that could be used when working with MLLs or to develop language in math)
Asset frame	The practice named is specifically described as honoring student assets or responds to a question about honoring assets.
Deficit frame	The practice named is described as a way to address or fix a perceived deficit in students (e.g., not speaking English or not comprehending).
Unclear/neutral frame	The practice named could use an asset-oriented or deficit-oriented, but there is not enough evidence to say.
Problematizing practices	A practice is named as problematic for being deficit-oriented or for having a negative impact on MLLs.

For research question two, we considered the tensions PSTs encounter when attempting to teach MLLs in asset-oriented ways. We began by identifying areas where PSTs' perspectives on teaching MLLs seem to diverge, as these may indicate where PSTs are grappling with how best to teach multilingual students. We descriptively coded moments in the discussion transcripts where PSTs' perspectives seemed to diverge from us or each other indicated by instances where they shared differing opinions from a peer's idea, asked questions about each other's ideas, or pushed back on the material presented by the instructors. We then looked at the portions of each discussion where there were multiple instances of divergence that might indicate central tensions to building asset frames of MLLs. In the findings we describe three vignettes that were characterized by multiple instances of divergence.

Findings

RQ 1: What did PSTs Name as Potential Asset-Oriented Practices for Working with MLLs and Language Development in Math?

We found 58 instances where PSTs mentioned instructional practices related to language in math (see Figure 1 for code frequency). They described a range of practices, including using manipulatives or visual images, creating a flip chart with key terms, translating materials, using

intentional partnering, using small group instruction, breaking down word problems with the whole class, and teaching explicit word problem comprehension strategies. In 21 of the instances where PSTs named instructional practices, they were problematizing the practices of other teachers. Both Justine's and Alice's experiences provide examples of PSTs problematizing practices. In the narrative discussion, Justine reflected on the impact of assigning some students easier work, which would lead students to compare themselves to their peers. She explained that if a teacher used this practice, then "[students] will give up wanting to learn... they will just realize, 'oh, I'm behind and everybody else.'" In the research talk, Alice described a practice from her field placement that she thought was problematic. She shared, "the way that [our math curriculum] works, they introduced numeric values of 4 plus 4. And students are supposed to master that before they do the word problems. That didn't work well for our [MLLs]." She continued to explain that the assessments used in her field placement drew heavily on word problems. She found it problematic that students would be given numeric problems in their daily work, but be required to complete word problems on assessments, thereby problematizing not teaching word problems but using them to assess understanding of math concepts. Both examples show how PSTs found some practices to be unsupportive of language development and were not practices they wanted to use.

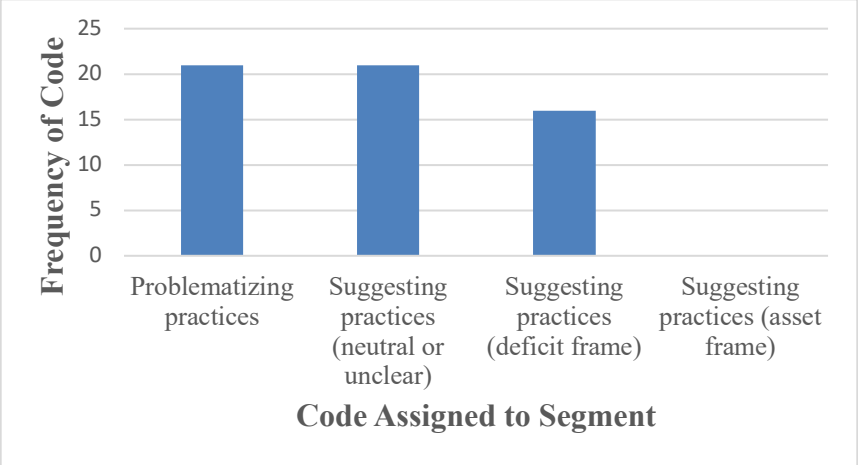

Figure 1: Frequency of Segment Codes

There were 37 instances of PSTs suggesting practices they would use—21 instances framing students in neutral or unclear ways and 16 framing students in deficit ways. Examples of unclear or neutrally-framed practices included when Maggie described a practice of "putting English in Spanish and Spanish in English," without elaborating on whether this was to support a deficit (i.e., not speaking English proficiently) or to build on an asset (i.e., drawing on their linguistic repertoire). Anna described offering read-alouds as an option for all students when she shared, "we'll be like 'if you need any problem read out loud for you like we'll just go read it out for you and then you can ask questions, too.'" This was also marked as unclear/neutral because she did not frame it as addressing a deficit (i.e., fixing their comprehension) or an asset (i.e., giving students opportunities to make meaning for themselves).

Practices framed around students' deficits ranged from subtle to more explicit. Ollie shared that she thought an important practice was to separate MLLs who speak the same language at home. She said, "I think seating charts are very vital. Because there's one student [who is fluent

in both languages], and I don't want students to feel like they have to have the burden to be a translator." While she was attempting to be considerate of the workload of the student who could translate for students still learning English, she also subtly described the student who needed to be translated for as a burden. In other words, not speaking English well enough is a deficit, and it is the teacher's role to ensure students are not held responsible for that deficit (i.e., creating a seating chart). Callie more explicitly described deficits when she explained that her MLLs were not receiving support in her field placement classroom. She shared, "I come from a place of understanding and frustration about this [statement] mainly because we do have you have two kids who are so low in their English language knowledge because they are English language learners. And because we've had such a big class, my teacher hasn't had time to like sit with her and like sound out each word, give her the meaning for each word." She described MLLs as "low" (i.e., deficit frame) while suggesting that they would benefit from a teacher sounding out words (i.e., a teaching practice). In another, more explicit example, Gina shared the practice of creating a chart of key terms and applying a deficit frame to MLLs. She said, "If you think this kid is not linguistically up to snuff… then maybe they should have like a little flip chart of key terms."

Overall, PSTs attempted to problematize classroom practices in about one-third of the practices they discussed. In the other two-thirds of the practices discussed, PSTs suggested instructional practices that framed MLLs in deficit or unclear ways. Notably, no practices were shared using asset framing of MLLs (i.e., none of the practices named explicitly noted how PSTs were noticing or leveraging students' linguistic, cultural, or mathematical assets).

RQ 2: What Tensions Around Practices for Working with MLLs and Language Development in Math Came Up in the Discussions?

There were three notable tensions around practice that came up in each of the three discussions. In the narrative discussion, the instructor asked PSTs to identify the deficit in a common discourse about language. Initially, the PSTs noted that the deficit stemmed from the teacher not believing in students' mathematical ability. Carter shared,

> You don't want to simplify [the math] to the point that they're losing the skills that they need to be building up. You can't just simplify the task and say, "oh, well, since you can't read English, I'll just be loose [with expectations]."

She challenged teachers' assumptions that mathematical ability is the same as language ability and argued that teachers shouldn't lower their expectations for MLLs because of language. Tina agreed with this idea, arguing that there was a language barrier for the student, but that the teacher should "talk about the actual math problem versus the comprehension." This seemed to be the general consensus of the cohort, that the student does have language deficits but that the teacher saying the discourse was making unfair deficit judgments about their math ability, until Dillan shook his head and interjected, "to think about language skills as an absence of it assumes that these students don't already have a primary language that they're successful in, which is where the deficit problem comes up." His argument was that seeing MLLs' English proficiency as a deficit was actually at the heart of the statement, similar to the statements of his peers. The key tension for PSTs was whether assumptions were being made about MLLs' ability to do math because of language *or* whether being an MLL was being seen inherently a deficit (*or* both).

In the lingering questions discussion, the instructor shared a strategy for highlighting students' linguistic assets, inviting PSTs to teach words in multiple languages as they worked through a word problem featuring strawberries. She called on a Korean PST to share the word

for strawberry in Korean. The instructor intended to show how mathematics can be a space for including language beyond the language of instruction, and how it can support students in making sense of word problems in multiple languages. Gina raised her hand to ask a question about this practice saying, "In another class we learned that it is not ok to ask Students of Color to share their experiences because it is 'tokenizing.' Would this not be an example of tokenizing?" Several other PSTs chimed in, "no," and "that's not what she meant here." Others looked uncertain. This moment highlights a second tension PSTs experienced when reflecting on asset-framed practices—whether attempting to honor home languages and multilingualism by inviting languages into the classroom can be tokenizing.

The research discussion sparked the most debate of the three discussions around the question: should MLLs be asked to do word problems? As PSTs read the research summary and considered what research says about working with language in math, a specific line initiated debate. It said, "Alt et al. (2014) found that when language–heavy math tasks were reduced in language load, ELLs performed as well as their monolingual peers." This line was included in the research summary to debunk any ideas that MLLs are not as mathematical as their peers, which PSTs had already problematized in the narrative discussion. However, some PSTs interpreted this to mean that if teachers do not give MLLs language-heavy math tasks then they will be more successful. PSTs generally did not know how to handle this idea. Alice argued that it wasn't fair that MLLs were assessed using word problems, saying, "I know they can do it, but then on the exit ticket, we're having to give them a 0 or 1 because they can't read it." Responding to this idea, Devin asked the instructor, "on their exit tickets—until they're able to comprehend word problems as a whole—would you recommend just having the math already written?" She wondered whether it might be fairer to assess MLL's operations solely with numbers, without reading. Gina did not like the idea of simplifying word problems for MLLs. She described her concern that it might hinder their future development sharing,

> At some point when their comprehension is up to snuff, they'll get thrown into these more difficult questions—word problems that will require more out of them, and they might not be able to meet that level that they're being put into.

Carter wondered, "wouldn't translating be a better option than just simplifying the language?" The tension in this discussion centered on whether using word problems would be harmful or beneficial to MLLs' mathematical development.

Discussion

Despite explicit work in the math methods course to build PSTs' asset-orientations towards MLLs, their framing of instructional practices and surfaced tensions point to a continued need to intentionally name and highlight strategies that recognize and build on students' existing strengths. Our findings showed that PSTs were beginning to problematize practices that viewed MLLs' math ability in deficit ways, and they could name a range of practices to use with MLLs. However, they were not yet explicitly describing practices that used an asset frame of MLLs. Additionally, several tensions arose when attempting to shift from deficit to asset frames of MLLs' competence. First, there was a tension about whether deficit frames about MLLs involved making assumptions about ability because of language, or assumptions that speaking languages other than English was a deficit. Second, PSTs worried that attempting to bring home language into the math classroom could sometimes be tokenizing. Third, PSTs debated whether using word problems was beneficial or harmful for MLLs.

These findings have implications for both teacher education and research. When creating opportunities for PSTs to interrogate deficit discourses and to use asset frames to select instructional practices for MLLs, it is important that teacher educators are explicit in naming practices using an asset frame. This work must attend to both deficits about innate ability (Larina & Markina, 2020; Dweck, 2006) and to assumptions of linguistic hegemony (Wiley, 2014). This includes teaching PSTs strategies that make opportunities for MLLs to access mathematics without reducing the cognitive demand. Furthermore, teacher educators must foreground students' linguistic capital (Yosso, 2005) and explain how practices can build from this capital. At the same time, the work is not merely engaging PSTs in discussions for one semester, but rather an ongoing practice of considering asset-oriented ways to work with MLLs that moves beyond being superficial or tokenizing (Ladson-Billings, 2014). Additionally, if we want to close the implementation gap in evidence-based practices while also framing MLLs in an asset-based way, we need more research that presents MLLs' knowledge in asset-oriented ways and includes practices that build on their strengths (Jones & Marchant, 2021).

EXPLORING BLACK EDUCATORS' PERSPECTIVES OF CULTURALLY RELEVANT PEDAGOGY WITH BLACK STUDENTS

Jermaine R. Howell
Michigan State University
howell97@msu.edu

This research study explored the perspectives of Black educators (elementary teachers, a math coach, and school administrators) on the benefits, support, and challenges of implementing culturally relevant pedagogy and its three tenets (academic success, cultural competence, and critical consciousness) when engaging Black students during math instruction. The perspectives from the Black educators provided (a) practical approaches of CRP to support and enhance their Black students' learning and doing of mathematics, (b) instructional support provided to support the math teaching practices of CRP, and (c) the challenges when implementing culturally relevant pedagogy. The study concludes with implications to address the challenges experienced by elementary teachers when implementing CRP during mathematics instruction and potential support that can be provided by math coaches and school administrators.

Keywords: Culturally Relevant Pedagogy, Black Students, Mathematics, Equity

In public elementary classrooms in the U.S., educators are encouraged to implement asset-based pedagogies to disrupt the current systems of inequity and injustice experienced by Black students. Some of these asset-based pedagogies include: culturally relevant pedagogy (CRP); culturally responsive teaching (CResT); and culturally sustaining pedagogy (CSP). Educational researchers continue to examine how these asset-based pedagogies support Black students' learning, promote educational equity, and disrupt systemic inequities that have negatively affected Black students when learning and doing mathematics (Alim & Paris, 2017; Alim et al., 2020; Gay, 2000, 2018; Ladson-Billings, 1995a, 1995b, 2014, 2021; Martin, 2012; Matthews et al., 2022; Paris, 2012, 2021; Paris & Alim, 2014, 2017; Zavala & Aguirre, 2024). However, the perspectives of Black educators' implementation of asset-based pedagogies to support and enhance the mathematical learning and doing of Black students have been underinvestigated.

In connecting the teaching, learning, and doing of mathematics to be relevant to Black students' culture, the importance of culture must be recognized, celebrated, nurtured, and sustained inside the classroom. Ladson-Billings (1997) noted that culture "refers to the deep structures of knowing, understanding, acting, and being in the world" (p. 700). Tillman (2002) further defined culture as "a group's individual and collective ways of thinking, believing, and knowing, which includes their shared experiences, consciousness, skills, values, forms of expression, social institutions, and behaviors" (p. 2). Recognizing the importance of Black students' culture inside the classroom disrupts existing notions that often describe mathematics education as culture-free (Bishop, 1988; Joseph, 2021). Leonard and Martin (2013) move this notion further by articulating how Black students' culture plays a vital role in their learning and doing of mathematics in U.S. classrooms.

Theoretical Framework

The study is grounded in the work of culturally relevant pedagogy. The research of CRP is first explained, followed by its three tenets that provide a description of teaching and learning practices that must be enacted when engaging Black students during mathematics instruction.

Culturally Relevant Pedagogy

The theorization of CRP came into existence to foster support and enhance the educational experiences of Black students in the U.S. school system. Although there have been countless research studies on the lack of educational opportunities and inequities faced by Black students, the theorization of CRP exemplified teaching and learning practices that disrupt systemic practices and inequities experienced by Black students. Ladson-Billings (1995a) asserted that CRP is a "pedagogy of opposition that is committed to collective empowerment" (p. 160). Ladson-Billings (1995a, 1995b, 2014, 2021) further asserted that CRP is grounded in three tenets: academic success, cultural competence, and critical consciousness. Academic success emphasizes the need for equitable learning for all Black students to achieve their full potential as learners inside and outside the classroom. Cultural competence ensures Black students' cultural identities and backgrounds are incorporated throughout different aspects of their learning and school experiences. Critical consciousness enables Black students to use their learning to examine and critique inequitable practices in order to create change and take action. In welcoming and remixing the work of CRP, Ladson-Billings (2014) articulated that CSP comes in where the beat drops of CRP toward "recreat[ing] instructional spaces to ensure that consistently marginalized students are repositioned into a place of normativity" (p. 76). Ladson-Billings (2014) further asserted that the work of CSP builds on CRP, which holds firm to the notion that students must be represented as subjects and not objects inside the classroom.

Methods

This research study incorporated a qualitative inquiry design (Creswell & Poth, 2025) with Zoom online interviews to collect data from Black elementary teachers, a Black math coach, and Black school administrators on their perspectives of CRP to support and enhance the teaching and learning of mathematics with Black students. This study was guided by the question: *What are the perspectives of Black educators on implementing Culturally Relevant Pedagogy to support and enhance Black students' learning of mathematics?* From this guiding question, two specific research questions were created.

Research Questions

1. What math teaching practices do Black educators (elementary teachers, math coaches, and school administrators) discuss when describing and explaining their implementation of Culturally Relevant Pedagogy with Black students?
2. What types of support do Black math coaches and Black school administrators provide to teachers implementing Culturally Relevant Pedagogy in mathematics instruction with Black students?

Sample Population and Locations

The research participants consisted of Black educators (three Black elementary teachers, one Black math coach, and two Black school administrators) in both urban and suburban school districts located in a Midwestern and Southern state of the U.S. The selection of the participants (see Table 1) encompassed Creswell & Poth's (2025) purposeful sampling to ensure the Black educators had prior knowledge of CRP and its implementation during mathematics instruction with Black students. The participants were selected based on their race (Black); in addition to completing a narrative Qualtrics survey to explain their prior knowledge and learning of CRP, instructional practices of CRP in mathematics with Black students, and professional learning/support on implementing CRP. The selection criteria also required participants to teach

or work with Black students in the classrooms or school building, with an emphasis on mathematics education.

Table 1: Description of the Research Participants

Pseudonyms	Gender	Highest Education	Race	Education Experiences (Years)	Role	School Demographics and Location
Ms. Clarke	F	M.Ed.	Black	21	K-2 Math Teacher & Interventionist	Midwestern Urban
Mr. Mason	M	B.Ed.	Black	9	4th Grade Teacher	Midwestern Urban
Ms. Johnson	F	M.Ed.	Black	20	4th Grade Teacher	Southern Suburban
Ms. Brown	F	M.Ed.	Black	17	Instructional Math Coach	Southern Suburban
Ms. Dixon	F	M.Ed.	Black	20	School Administrator	Southern Suburban
Dr. Francis	F	Ed.D.	Black	14	School Administrator	Southern Urban

Note. F = female; M = male; M.Ed. = Master of Education; B.Ed. = Bachelor of Education; Ed.D. = Doctor of Education

Data Collection

The data for this study were collected through one-on-one semi-structured recorded Zoom interviews with Black educators. One-on-one online Zoom interviews were used instead of in-person interviews due to the location of the selected educators (i.e., Midwestern and Southern states) in the U.S. The interview questions were designed and grouped using the guiding question and specific research questions. For example, all participants answered interview questions relating to the guiding question and research question one. However, in contrast, only the Black math coach and Black school administrators answered interview questions relating to research question two.

Data Analysis

The interview data were transcribed using Zoom transcription software. To ensure accuracy in the transcription, an additional review of transcribed data was done by relisting and rewatching the recorded video interviews to ensure the data from each interview transcript correlated with the information shared by each participant. A deductive analysis (Galman, 2018; Tisdell et al., 2025) using in vivo coding (Saldaña, 2016) was used to code the transcribed data based on the three tenets of CRP—academic success, cultural competence, and critical consciousness (Ladson-Billings, 1995a). Based on the description of each CRP tenet, the Black educators' math teaching practices were coded by categorizing their responses under each tenet. For example, Mr. Mason expressed how he set high expectations for all his Black students to demonstrate their mathematical learning abilities. This response was coded under the CRP tenet of academic success. In addition, specific words and sentences were used to code the math teaching practices. The support that was provided by the Black math coach and Black school

administrators was also coded deductively based on the following categories: (a) general instructional support; (b) instructional support to implement the three tenets of CRP; and (c) examples of professional learning support.

In bridging the theory-to-practice gap experienced by teachers when implementing CRP during mathematics instruction, second-cycle coding was conducted using an inductive analysis (Galman, 2018; Tisdell et al., 2025) by applying the focused coding strategy (Saldaña, 2016) to identify categories and sub-categories of culturally relevant math teaching practices that would have been missed during deductive analysis. To identify categories and sub-categories, the interview transcript of each Black educator was re-read to develop sub-codes of mathematics teaching practices explained by the Black elementary teachers. These sub-codes were further categorized into five themes. Based on these themes, specific CRP math practices (sub-codes) were shared to support classroom teachers in implementing the CRP tenets in mathematics classrooms. The incorporation of inter-rater reliability was carried out by two colleagues in a qualitative data analysis group. These colleagues read through the interview transcripts and checked the codes and sub-codes that were identified.

Findings

The elementary teachers, math coach, and school administrators described and explained various benefits of CRP when engaging Black students in mathematics instruction. A prominent theme in the described benefits when implementing CRP focused on addressing the concern of inequity in mathematics classrooms by ensuring math teaching practices incorporate Black students' identity, language, culture, background, and community. The Black educators' explanations targeted the CRP tenet of academic success, along with connections to developing Black students' cultural competence and critical consciousness when learning and doing mathematics.

Section 1: Black Educators' Perspectives on the Benefits of Culturally Relevant (Math) Pedagogy

Ms. Johnson explained that through the implementation of CRP, her Black students see their cultural backgrounds represented during mathematics instruction. She also adapts the school curriculum to cater to the learning needs of her Black students.

Ms. Brown shared that this form of pedagogy [CRP] "builds their [Black students] confidence and toward seeing themselves as mathematicians."

Ms. Dixon expressed that CRP disrupts inequitable practices inside classrooms. Dr. Francis explained that CRP ensures Black students are held accountable during math instruction. She further explained that CRP affirms the notion that they are "capable and brilliant" at solving math problems.

CRP Math Teaching Practices

The three CRP tenets (academic success, cultural competence, and critical consciousness) were operationalized to identify the math teaching practices of the Black educators. For each tenet, the Black educators' perspectives and examples were reported based on their specific implementation of CRP. The areas of strength and growth for each CRP tenet were also discussed.

Academic success. Ms. Johnson explained how she incorporates sports, music, family gatherings, and other activities into mathematics scenarios that are relevant and real-life to her Black students' lives and communities. This further allows her Black students to utilize their unique ways of solving math problems and develop a mathematical identity in her Black students

to enhance their academic success. Ms. Johnson also noted how she introduces her Black students to Black mathematicians and Black scientists to learn about their history and contributions to further develop their mathematical identity as people who look like them.

Ms. Brown described and explained the importance of "relevant" in culturally relevant pedagogy by sharing that math lessons must be relevant to the current time and culture of the students. She also explained that the mathematics classroom must be inclusive and build on Black students' funds of knowledge and prior learning experiences. Ms. Brown emphasized the importance of connecting mathematics with literacy instruction by using a text that talks about the cultural history of mathematics (e.g., multiplication) while also connecting the lesson to real-life problems.

Ms. Dixon noted that Black students' background knowledge, culture, and lived experiences must be included in all lessons. She shared that: "[Black] students can learn or acquire valuable math skills that can translate to all content areas and life—one of those is just the ability to grapple during productive struggle and the ability to question and think critically." Dr. Francis, however, explained how her teachers develop their Black students' academic success by engaging them in project-based math activities.

Cultural competence. Mr. Mason explained how he builds relationships with his Black students by learning about their culture and background, and utilizing that knowledge when planning and teaching math instruction. He explained: "Relationships are my big thing—to kind of have that support and that background of students, so I know more about them. They know more about me, so we can make references to things. I understand their languages and the things that they're into." Ms. Johnson explained that in developing her Black students' cultural competence, she ensures they utilize their cultural backgrounds in math lessons to support their learning and engagement. Ms. Johnson also explained how she adapts the curriculum to ensure her Black students' culture is represented in the math content they are learning.

Ms. Brown provided an example that distinguished the practice of cultural competence from multicultural education. She noted: "When we talk about, I know a lot of teachers think culturally relevant pedagogy is just making sure all students' cultures are represented in the classroom. But that's more so multicultural education, but when we're talking about culturally relevant, that's talking and thinking about their Black students' current culture and ensuring they learn more about it."

From an administrator's stance, Ms. Dixon shared that implementing cultural competence requires classroom teachers to "see and know [their] Black students and be able to leverage their cultural and linguistic experiences in instruction."

Critical consciousness. Mr. Mason explained how he connects his math lesson to his Black students' community, so that they can learn more about the community. Ms. Clarke shared that she incorporates the teaching of Black history into her math lessons for students to learn more about their historical backgrounds. She also shared: "We introduce and expose our scholars to the [Black] history; we expose them to current events going on in the Black community. We expose them to the good and the bad as well." Ms. Johnson's explanation for developing her Black students' critical consciousness includes the incorporation of Black mathematicians and future careers that use math to raise students' awareness during mathematics instruction.

Although the Black elementary teachers incorporated their Black students' community, Black history, and Black mathematicians into their math lessons to develop their critical consciousness, based on the CRP literature, further extension might be impactful for students to use their mathematical knowledge to critique structural inequity and take action. I question,

however, how the terminology of critical consciousness, as used in the CRP description, is interpreted the same by educators during mathematics instruction.

The Black math coach and Black school administrators were asked the question: How do the math teachers under your leadership support Black students to develop and apply critical consciousness when learning math? I was unable to code the responses provided by the Black math coach and Black school administrator as examples in developing Black students' critical consciousness. For example, Ms. Dixon expressed that it was an area they are working on.

Teaching Practices for Culturally Relevant (Math) Pedagogy

To further investigate the Black educators' math teaching practices to develop their Black students' critical consciousness, the interview data were reanalyzed inductively to identify math teaching practices that could have been missed during the first cycle of deductive coding. The findings revealed approaches along with culturally relevant math teaching practices (see Table 2) that were shared by the Black elementary teachers, Black math coach, and Black school administrators. Five themes emerged relating to culturally relevant math teaching practices: (a) inclusive learning environment; (b) learning of mathematics; (c) mathematical identity; (d) relevant mathematics instruction and cultural connection; and (e) CRP guiding principles for math.

Table 2: Teaching Practices for Culturally Relevant (Math) Pedagogy

Approaches	Culturally Relevant Math Teaching Practices
Inclusive Learning Environment	(a) Including students in the learning process using their strengths; (b) Utilizing students' culture, race, language, community, and background knowledge and experiences as a form of inclusion in the learning process
Learning and Doing Mathematics	(a) Developing math confidence in Black students; (b) Teaching Black students how to think when solving math problems by including their background and cultural knowledge; (c) Identifying math competence in Black students and encouraging them to use it; and (d) Creating real-world math connections and applications
Mathematical Identity	(a) Developing Black students' mathematical identity; (b) Utilizing the math practice standards; (c) Engaging in collaborative math discourse; (d) Challenging Black students' thinking when learning math; (e) Developing a mathematical identity in Black students - participating in critical thinking; (f) Connecting out-of-school experiences to in-school mathematics
Relevant Math Instruction & Cultural Connection	(a) Developing the knowledge of your students; (b) Knowing your students—knowing their interest in math, identifying their strengths and areas of growth in math; (c) Connecting math lessons to current learning (e.g., gaming, technology, current interests, real life); (d) connecting students' learning to the current culture; (e) modifying the curriculum to students' cultures and background knowledge

CRP Guiding Principles for Math	(a) Unpacking the learning target; (b) Utilizing academic language; (c) Providing access to all students in learning mathematics (Gutiérrez, 2012 – access & equity); (d) Providing multiple entries into the lesson for different learning levels; (e) Providing scaffolds that are responsive to all students' culture and learning needs; (f) Creating classroom culture for students to feel empowered; Building a teamwork and collaboration learning environment

Note. CRP = Culturally Relevant Pedagogy

Section 2: Instructional Support and Challenges for Implementing Culturally Relevant (Math) Pedagogy

Ms. Brown described how she provides book chapters and research articles that explain CRP and equity in mathematics teaching and learning. Ms. Brown also expressed the usage of the coaching cycle, which provides yearlong support to teachers on implementing CRP when teaching mathematics with Black students. As an administrator, Ms. Dixon explained that she allows her teachers to engage in diversity and racial equity training in the form of professional development to support their racially and linguistically diverse students.

A constant theme across Black educators' responses was that the curricula that are given by the school district for teachers to use during instruction do not cater to the cultural, racial, linguistic, and community backgrounds of their Black students. For example, Ms. Johnson argued that although she adapts the curriculum and redesigns her math teaching practices to be culturally relevant to their Black students, she explained that on state and district standardized assessments, the math questions and tasks do not connect to her Black students' cultural, racial, linguistic, and community backgrounds. Similarly, Ms. Dixon explained that: "all curricula are culturally relevant, but culturally relevant to the dominant White culture in U.S. classrooms." She further explained that classroom teachers with Black students must search for additional resources to address the cultural mismatch and content of the curricula they are required to teach.

Conclusion & Implications

The findings of this study add to the existing research on culturally relevant pedagogy, but importantly, the perspectives of Black educators when teaching and working with Black students in mathematics education. All six Black educators provided a thoughtful explanation of the culturally relevant math practices to cater to the academic, social, cultural, and sociopolitical needs of Black students. The Black educators expressed that the learning of mathematics must not operate in a vacuum that only facilitates the teaching and learning of mathematics based on the curriculum, but must also connect to Black students' cultures, backgrounds, identities, ways of knowing and doing, and real-life experiences and situations. The shift from the traditional approach to teaching mathematics to the implementation of CRP and CSP is to ensure Black students can learn and apply mathematics to solve problems inside and outside of the classroom. The implementation of CRP addresses the curricula mismatch, which at times fails to connect learning materials to the cultural, linguistic, and community background of Black students.

In implementing culturally relevant pedagogy in mathematics education, the importance of relevance was emphasized by Ms. Brown to ensure math instruction connected to current time, culture, and real-life experiences and situations of Black students. Both Ms. Johnson and Ms. Brown shared the role the curriculum plays in Black students' learning, motivation, and engagement during math instruction. Ms. Johnson expressed that through curriculum adaptation,

her Black students can see themselves represented, along with their cultures and backgrounds, in the math lesson. This math teaching practice by Ms. Johnson further develops the math confidence in her Black students, which was also alluded to by Ms. Brown. Adding to these approaches to support and enhance Black students' learning and doing mathematics, Ms. Dixon emphasized the notion that equitable math instruction must be implemented to disrupt the practices of providing Black students with remedial and below-grade-level math instruction.

To address the challenges often experienced by teachers to implementation CRP inside the classroom, I recommend professional learning in the form of communities of practice (Wenger, 2000; Wenger et al., 2002) within a grade-level and school-wide setting. This will allow educators to unpack theoretical and practical teaching and learning approaches of culturally relevant and sustaining pedagogies when teaching mathematics. Additionally, administrators (and teachers) must ensure they are updated with the current research literature (theoretical and practical) to further support their learning and instructional practices of their teachers when engaging Black students during mathematics instruction.

KNOWLEDGE PRODUCTION IN PIECES: ANALYZING EPISTEMIC NICHES IN MATHEMATICS EDUCATION RESEARCH

PRODUCCIÓN DE CONOCIMIENTO EN TROZOS: ANÁLISIS DE NICHOS EPISTÉMICOS EN LA INVESTIGACIÓN EN EDUCACIÓN MATEMÁTICA

Gregory V. Larnell
University of Illinois Chicago
glarnell@uic.edu

This theoretical paper builds on Reys, Reys, and Shih's (2021) concept of epistemic niches in mathematics education by advocating analyses that interrogate the power relations shaping knowledge production. Adopting a mereological perspective—examining how parts constitute the disciplinary whole—three dangers of niche formation are discussed: epistemic anchoring (theoretical rigidity), severe partitioning (mutual unintelligibility), and ghettoization (systematic marginalization). Using equity-focused scholarship as a case study, the commentary argues that these dynamics reproduce epistemic injustice, particularly affecting scholars of color. The commentary calls for a critical meta-epistemic agenda: sustained reflexivity about whose knowledge counts, under what conditions niches achieve legitimacy, and how mathematics education research can address equity while tolerating epistemic injustice in its own structures.

Keywords: Doctoral Education; Equity, Inclusion, and Diversity

Research in mathematics education in the United States issues from a loose collection of "jagged, uneven pieces"—a fragmented constellation of discrete yet overlapping epistemic niches (Lawrence-Lightfoot, 1983; Silver & Kilpatrick, 1994). These niches, stitched together as institutional networks of universities, school systems, research institutes, funding agencies, and political actors, constitute the terrain on which academic knowledge about mathematics teaching and learning is produced, validated, and circulated. Like most academic fields, mathematics education has evolved into an assemblage of communities of practice (Wenger, 1998), organized around core areas such as learning, teaching, and curriculum development.

The history of knowledge production in mathematics education is fundamentally a story of these niches—their formation, evolution, institutionalization, and sometimes their dissolution. Many are familiar by name: the School Mathematics Study Group (SMSG), the National Council of Teachers of Mathematics (NCTM), QUASAR, the Algebra Project, NSF Centers for Learning and Teaching, TODOS: Mathematics for ALL. These represent relatively independent sub-specializations, each with distinct intellectual genealogies, methodological commitments, and epistemological orientations.

As the field evolves, what Kilpatrick (2013) calls "critical reflexivity" becomes increasingly necessary. We need ongoing accounting of these sub-specializations: their progenitors and interlocutors, their purposes and agendas, their contributions over time, and crucially, the conditions under which they emerge, persist, or disappear. This is not a call for surveillance but for a critical, meta-epistemic agenda: a concerted way of knowing about our knowing in mathematics education.

Analyzing Epistemic Niches: A Comment on Reys, Reys, and Shih (2021)

Reys, Reys, and Shih's (2021) contribution extends a valuable longitudinal tradition of surveying doctoral programs in mathematics education. Their mapping of specialized doctoral

programs provides important descriptive information about the contemporary landscape. However, their analysis leaves critical dimensions of epistemic niche formation unexplored. By treating doctoral programs as the primary unit in a frequency-based, descriptive analysis, the results sidestep fundamental questions about power, access, and epistemic injustice, risking naturalizing the current configuration as simply normal development without interrogating the complex processes by which specialized niches arise and the barriers they navigate toward institutionalization.

While doctoral programs offer certain affordances as a unit of analysis—they are institutionalized, relatively stable, and documentable—this choice carries significant limitations. As Gray and Lowery (1996) suggest, the question of what constitutes the appropriate unit becomes paramount. If epistemic niches are fundamentally about people and knowledge production rather than institutional structures, then focusing exclusively on programs may obscure as much as it reveals. Deeper layers of analysis—who enters and what knowledges are produced from known programs—would be needed.

Treating programs as the primary unit tends to render doctoral students as passive actors. As Pallas (2001) argues, this perspective "views students as relatively passive participants in the socialization process" and "assumes that students' personal and social origins, and hence their personal epistemologies, are largely irrelevant to research preparation—a particularly dangerous assumption in view of the changing composition of today's graduate students" (p. 7). This overlooks how prospective scholars choose their programs, navigate participation within them, and how their epistemic purposes influence their trajectories and contributions.

Most consequentially, focusing on doctoral programs without interrogating their epistemological and ideological orientations obscures how power operates in doctoral socialization. This approach "does not make problematic whose skills and values are internalized through the socialization process" (Pallas, p. 7). This silence regarding power becomes particularly acute when we consider persistent underrepresentation of scholars of color. As Young (2001) observes, "despite their growing presence in doctoral programs, people of color remain underrepresented among the contributors to knowledge production, with critical consequences for the nature and range of perspectives, understandings, and paradigms that inform this work" (p. 4).

Epistemic Niches and the Problem of Equity

The focus on epistemic niches becomes particularly urgent when we consider equity—not merely as a research topic but equity in the structure of knowledge production itself. What Berenstain, Dotson, Paredes, Ruíz, and Silva (2021) observe about colonial epistemologies applies to academic fields: "the injustice of epistemic injustice is not the exception but the rule... The injustice goes all the way down in the systems that produce it—and it does so, for the most part, by design" (p. 3).

The "Equity Niche" as Case Study

The emergence of an "equity niche" in mathematics education—focused on access, representation, identity, and justice—provides an instructive case. Beginning around the 1980s and gaining momentum through the 1990s, researchers and practitioners organized scholarship around questions of equity, challenging the field's tendency to treat differential outcomes as incidental.

Two prominent examples illustrate different approaches: QUASAR (Quantitative Understanding: Amplifying Student Achievement and Reasoning) and the Algebra Project. QUASAR, funded by the Ford Foundation and based at University of Pittsburgh, represented a

university-based research initiative focused on improving mathematics instruction in middle schools serving economically disadvantaged students. The Algebra Project, founded by Dr. Robert P. Moses, emerged from community organizing traditions and positioned mathematical literacy explicitly as a civil right.

Both contributed significantly to knowledge about equity yet occupied different positions within the field's epistemic landscape. QUASAR operated largely within mainstream research paradigms and institutional structures. The Algebra Project, while influential and well-supported, often occupied a more marginal position—celebrated for its grassroots approach but sometimes viewed as less "research-oriented," despite producing important knowledge about mathematics teaching and learning. This differential positioning reveals something crucial: the question is not simply whether equity-focused work exists, but whose equity work, grounded in which epistemological and methodological traditions, achieves recognition and institutional support.

The concentration of equity-focused scholarship into a particular niche carries risks that Gray and Lowery (1996) term "ghettoization"—the cordoning off of specific concerns into specialized subfields that can then be ignored by the mainstream. Bullock (2014) cautioned about this emergent danger. When equity becomes a niche rather than a cross-cutting concern, problematic dynamics emerge: the broader field can claim to address equity by pointing to equity-focused scholars and programs, without fundamentally examining how its own structures, methods, and theories may reproduce inequity.

Epistemic Enclosure: Anchoring, Severe Partitioning, and Ghettoization

The metaphor of the niche borrows from ecology and carries connotations of natural fit and adaptive specialization. Yet this ecological framing risks obscuring the deeply social and political processes through which epistemic niches form, persist, and sometimes calcify. To understand these risks, we must distinguish between productive specialization—the necessary division of intellectual labor—and epistemic enclosure: the hardening of boundaries that prevents dialogue, limits circulation of ideas, and reproduces hierarchies of epistemic authority. Three interconnected dangers merit attention: epistemic anchoring, severe partitioning, and ghettoization.

Epistemic Anchoring Practices

Wilson (1973) observed that "the easiest and most prudent maintenance strategy is to develop autonomy—that is, a distinctive area of competence, a clearly demarcated and exclusively served clientele or membership, and undisputed jurisdiction over a function, service, goal, or cause" (as cited by Gray and Lowery, 1997, p. 28). While autonomy enables focused inquiry, it can also produce epistemic anchoring—the tendency of niches to become so firmly fixed to particular theoretical commitments, methodological approaches, or topical concerns that they cannot adapt to new questions or integrate insights from other communities.

Epistemic anchoring manifests when certain niches become synonymous with specific theoretical frameworks; scholars working within these niches may struggle to publish work diverging from established theoretical vocabularies. Graduate students socialized within anchored niches learn implicit rules about what constitutes legitimate scholarship—negotiating "the meaning of what counts as knowledge through interactions with others in the same community, as well as through exposure to reifications (e.g., books and articles), which are often interpreted in local terms" (Pallas, 2001, p. 9).

The danger is not specialization but rigidity. When niches become anchored, they risk paradigmatic insularity—the inability to recognize anomalies or integrate revolutionary insights because doing so would require abandoning commitments that define the niche's identity. This

reproduction occurs through doctoral education: students inherit not only intellectual tools but also boundaries of legitimate inquiry, learning to think within the niche rather than critically about it, creating epistemic path dependency.

Severe Partitioning and Balkanization

Beyond individual niche insularity lies severe partitioning: the fragmentation into mutually incomprehensible or hostile camps—what political scientists call balkanization. Pallas (2001) articulates this danger: "If educational researchers cannot understand and engage with one another, both within and across at least some educational research communities, the enterprise is doomed to failure. Thus, to prevent recurring epistemological single-mindedness, educational researchers will need to engage with multiple epistemological perspectives to the point that members of different communities can understand one another, despite, or perhaps through, their differences" (pp. 6–7).

In mathematics education, we observe partitioning along multiple fault lines: quantitative versus qualitative researchers, cognitive versus sociocultural theorists, learning versus teaching scholars, curriculum versus equity focus. The "math wars" represent the most severe and hostile partitioning in recent history. These divisions aren't inherently problematic—different questions require different approaches. Danger emerges when niches become so partitioned that scholars cannot engage meaningfully across boundaries.

Severe partitioning produces pathologies. It enables epistemic provincialism—assuming one's niche possesses the correct or most important approach. It facilitates mutual unintelligibility when niches develop highly specialized vocabularies without sustained dialogue. Most troublingly, it enables niches to ignore work challenging prevailing assumptions, providing plausible deniability: "That's not my area; that's what the equity people study." Balkanization becomes particularly dangerous when it maps onto ideological or identity-based differences, losing the field's capacity for productive disagreement.

Epistemic Ghettoization

The third and most consequential danger is epistemic ghettoization—the process by which certain niches become marked as marginal, applied, or less rigorous, effectively quarantining their insights from the mainstream. Unlike anchoring (internal rigidity) or partitioning (mutual separation), ghettoization is fundamentally about power and hierarchy, describing how some niches achieve epistemic authority while others are relegated to subordinate status.

The spatial metaphor is deliberate. Just as urban ghettos result from deliberate policies of segregation and disinvestment—not natural sorting—epistemic ghettos emerge from structured processes determining whose knowledge counts, whose questions matter, and whose methods are legitimate. The social conditions of broader society—segregation, gentrification, neoliberalism, intergenerational wealth hoarding, white flight—are not merely analogies but actual material and ideological forces shaping which scholars access elite institutions, sustained funding, and positions of influence.

Ghettoization manifests in how different research is valued and cited. Work focused on equity, particularly employing critical frameworks or community-based methods, often gets coded as "advocacy" rather than research, as "political" rather than scholarly. This coding justifies its exclusion from theoretical conversations shaping the field's core commitments. Equity-focused scholars may be celebrated for their "important work" while simultaneously passed over for editorial positions, theory-building invitations, or major awards.

This hierarchical coding has profound consequences for scholars of color. The problem is not merely numerical underrepresentation—it is that epistemological orientations and research

questions that scholars of color often bring are systematically devalued. When the equity niche becomes ghettoized, scholars whose lived experiences and intellectual commitments orient them toward questions of justice find their work marginalized, regardless of rigor or insight.

The danger extends beyond individual scholars to the field's epistemic health. When perspectives from marginalized niches cannot circulate freely, when their orientations cannot shape core theoretical debates, the field's knowledge becomes impoverished. We lose what standpoint theorists call "epistemic privilege"—the insight that "in a socially stratified society, different social positions yield distinctive epistemic positions, and some are better than others" (Siegel, 2006, p. 8). By ghettoizing equity-focused work, mathematics education cuts itself off from perspectives most able to illuminate how the field itself reproduces inequality.

The Compounding Effects

These three dangers—anchoring, partitioning, and ghettoization—reinforce one another. Epistemic anchoring increases partitioning likelihood, as rigid niches struggle to communicate. Partitioning facilitates ghettoization by allowing dominant niches to ignore marginalized ones. Ghettoization reinforces anchoring within marginalized niches, as scholars develop increasingly specialized languages to sustain work in hostile environments.

The result is an academic field that, despite genuine commitments to equity among many scholars, reproduces epistemic hierarchy through its structure. Doctoral students learn which questions are serious, which methods rigorous, which theories foundational. These lessons get encoded in hiring decisions, promotion processes, editorial practices, and funding priorities. Niches calcify into structures determining whose knowledge counts.

As Berenstain et al. (2021) remind us, this is not accidental: "the injustice goes all the way down in the systems that produce it—and it does so, for the most part, by design" (p. 3). The current configuration of epistemic niches in mathematics education emerged through structured, political decisions about funding, institutional prestige, methodological legitimacy, and theoretical authority. Addressing niche formation dangers requires more than encouraging dialogue or celebrating diversity—it requires confronting power relations determining which niches thrive and which struggle.

Toward Critical Reflexivity: Power and Accountability

If these dangers represent genuine threats to mathematics education's epistemic health, what might a constructive response look like? This is not a call for eliminating niches—specialization serves important functions. Nor is this conjuring false unity papering over genuine epistemological differences. Rather, this proposes a critical, meta-epistemic agenda: sustained, reflexive engagement with how we produce knowledge about mathematics education, who participates in that production, and whose interests current arrangements serve.

Make Power Visible

As Dotson (2018) argues, "What generates an assessment of an epistemological orientation as 'problematic' concerns the operative orienting variables of the analysis in question, e.g., what generates 'oughts,' including epistemic 'oughts'" (p. 130). We must interrogate not merely what different niches study or how, but why certain approaches achieve legitimacy while others are marginalized. This requires examining material conditions of knowledge production: Which institutions house which niches? Which receive sustained funding? Whose graduates obtain elite university positions? Which journals are "top tier," and which niches are represented on their editorial boards?

Making power visible means acknowledging that epistemic hierarchies are not natural outcomes of intellectual merit but products of historical and ongoing processes of inclusion and

exclusion. When quantitative methods are treated as inherently more rigorous than qualitative ones, when cognitive frameworks are deemed more fundamental than sociocultural ones, when research ignoring race and power is coded as "objective" while research centering them is coded as "political"—these are exercises of epistemic power requiring examination.

Epistemic Accountability

Niches should be held accountable not merely for quality of work produced within their paradigms, but for engagement with questions and perspectives challenging those paradigms. This means creating structures and incentives for cross-niche dialogue beyond superficial acknowledgment, insisting that scholars engage genuinely with perspectives different from their own.

Epistemic accountability extends to doctoral education. Mathematics education doctoral programs should be evaluated not only on graduation rates and job placements, but on whether they prepare students for epistemological diversity. As Pallas (2001) argues, preventing "recurring epistemological single-mindedness" requires that "educational researchers engage with multiple epistemological perspectives to the point that members of different communities can understand one another" (pp. 6–7). Doctoral programs should explicitly prepare students to work across epistemic boundaries, translate between theoretical languages, and recognize value in approaches different from their own.

Conclusion: Toward Ways of Knowing About Our Knowing

This commentary necessarily leaves much undone but hopefully stimulates dialogue. We need comprehensive functional analyses mapping how different epistemic niches operate—their funding sources, citation networks, reproduction through doctoral education, relationships to policy and practice. Such analyses would require substantial empirical work examining who produces knowledge in mathematics education, under what conditions, with what resources and constraints, and with what consequences.

The question of equity in knowledge production—not as research topic but in the structures through which knowledge is produced and validated—requires sustained engagement. Underrepresentation of scholars of color is not merely demographic but reflects and reproduces epistemic injustice. Dismantling these systems requires more than good intentions or procedural reforms; it demands fundamental rethinking of what counts as knowledge and who is authorized to produce it.

Silver and Kilpatrick's (1994) observation remains apt: what we see in the field, we see in ourselves. The fragmentation, mutual ignorance, limited awareness beyond our own plots—these are not merely organizational problems but epistemic ones. They reflect and produce a field that cannot fully account for its own knowledge production, that cannot critically examine conditions under which certain questions become central while others are marginalized, certain methods become standard while others deemed suspect, and certain scholars achieve influence while others struggle for recognition.

A critical, meta-epistemic agenda—toward ways of knowing about our knowing—is not a luxury but a necessity. Without sustained attention to how epistemic niches form, function, and relate to one another, mathematics education risks reproducing through its knowledge production structures the very inequities that many scholars study in mathematics classrooms. The field cannot adequately address equity in mathematics education while tolerating epistemic injustice in mathematics education research. By expanding the concept of niche to encompass critical analysis of power, attending to dangers alongside possibilities, and insisting that epistemic justice is integral to epistemic health, we may evolve the field toward critical reflexivity. The

epistemic niches we have, the epistemic niches we need, and the relationships among them—these are not settled questions but ongoing challenges demanding continued attention, critique, and collective commitment to a more just and epistemically robust field.

WHEN ASKING PARENTS HELPS OR NOT: SES DIFFERENCES IN PARENTAL MATH HELP-SEEKING AND ACHIEVEMENT

Jieun Lee

Kyunghoon Son
The University of Alabama
kson@ua.edu

This study examined elementary students' parental math help-seeking and its links to achievement across socioeconomic contexts. Open-ended responses were coded into six themes, including no hesitation and five barriers. Low SES students more often cited parental knowledge limits and emotional concerns. An exact test using dichotomized measure of hesitation showed significant group differences. Despite a shared tendency not to hesitate in seeking help, the high SES group demonstrated higher achievement than its low SES counterpart. Moreover, tutoring was associated with achievement differences only within the low SES group. Findings suggest help-seeking is context dependent and shaped by home resources, emotional climate, and access to alternative supports. Implications include strengthening emotionally safe family interactions, supporting parental math competence, and expanding school-based pathways for help.

Keywords: Elementary School Education; Equity, Inclusion, and Diversity; Communication

Purpose of the Study

Learning in mathematics emerges not only from formal instruction but also from the everyday interactions, expectations, and resources that surround children at home. Sociocultural perspectives emphasize that thinking is mediated by tools, language, and relationships (Vygotsky, 1978). In this view, the home is a consequential site where meanings about mathematics are negotiated and where identities as learners are formed (Anderson & Gold, 2006). Within this setting, parents are often the first adults to whom children turn when they encounter difficulty or curiosity.

Help-seeking is central to self-regulated learning (Karabenick & Newman, 2006), yet research on parental involvement has often treated requests for help as uniformly beneficial and has relied primarily on reports from adults rather than from children (Zhang et al., 2024). Less is known about how children themselves understand the decision to ask parents for help with mathematics, and how these understandings vary by SES. South Korea provides a compelling context where academic expectations are high, families differ widely in access to educational resources, and a substantial market for private supports coexists with public schooling (Kim et al., 2010). In such a context, children's help-seeking decisions are likely to be shaped by both structural conditions and relational dynamics at home.

Help-seeking is not merely a function of personal confidence or motivation but is embedded within sociocultural environments. Attending to these broader influences is essential for understanding variation in help-seeking behaviors and for shifting the discussion beyond individual responsibility toward the structural conditions that shape students' fair opportunity to learn. This perspective motivates attention to the home as a consequential learning setting and to socioeconomic differences in resources and emotional climate that condition when asking for help is feasible.

This study takes an exploratory approach to children's perceptions of seeking parental help in mathematics. Open-ended survey responses from South Korean elementary students are examined to identify how children describe the barriers and affordances of seeking

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

parental assistance with mathematics and these descriptions are situated in relation to SES. The aim is to clarify the phenomena that children themselves report, to map how these reports cluster into interpretable themes, and to outline how such themes can inform subsequent inquiry into connections between help-seeking, instructional opportunity, and achievement.

Accordingly, we ask two questions. First, how do students describe the barriers to seeking parental help in mathematics, and how do these descriptions organize into coherent categories? Second, how are students' parental help-seeking tendencies related to mathematics achievement within and across SES groups, and what patterns emerge when considering access to external supports such as private tutoring?

Theoretical Background

The model of the parent involvement process (Hoover-Dempsey & Sandler, 1997; Hoover-Dempsey et al., 2005) specify how parents become involved in their children's learning and how that involvement influences student outcomes across a series of levels (Whitaker, 2018). Our focus is on level one, which identifies three categories of motivators (i.e., personal, contextual, and parents' life context) that shape how parents engage with their children's learning.

First, personal motivators concern what parents believe about their role and their efficacy for supporting learning. Role construction captures parents' understandings of what they should do in relation to schoolwork, while efficacy reflects confidence that their efforts can make a difference in the child's success (Bandura, 1997; Hoover-Dempsey & Sandler, 1997). Second, contextual motivators arise from invitations by children, schools, and teachers (Hoover-Dempsey & Sandler, 1997). For example, the invitation from children signal that parental participation is valued (Baumrind, 1991). Third, parents' life context motivators refer to the practical conditions that enable or constrain involvement, including available time and energy, knowledge and skills, and access to social capital (Horvat et al., 2003; Hoover-Dempsey & Sandler, 1997).

Centering level one is warranted in the present study because these motivators are foundational for understanding parental participation in elementary mathematics. Extending the framework to the perspective of the child further clarifies the dynamics at home. Students appraise whether parents can assist with grade level mathematics, anticipate the emotional climate that help seeking may elicit, and consider the availability of alternative supports when parental assistance is limited. Framed this way, the model allows a nuanced analysis of how beliefs, invitations, and life context interact, and how those interactions may differ by SES.

A complementary foundation comes from Vygotskian sociocultural theory. Sociocultural perspectives conceptualize learning as participation in culturally organized activity mediated by tools, language, and social interaction (Vygotsky, 1978). From this standpoint, the home is not a passive backdrop but an active site where mathematical meanings are negotiated and where learner have opportunities to receive assistance from more knowledgeable others.

Taken together, these perspectives treat help seeking from parents as a social practice shaped by both structure and relationship. The present study integrates the two strands by centering student reports of perceived barriers, comparing their distribution across socioeconomic groups, and relating these perceptions to mathematics performance within groups.

Methods

This study employed a mixed-methods design. Both content analysis and statistical analysis were conducted to compare the similarities and differences between mathematical help-seeking behavior and achievement between high and low SES groups.

Mode of Inquiry

Qualitative analysis. Grounded in the Hoover-Dempsey and Sandler model of the parent involvement process (1997), qualitative coding proceeded through a combined deductive and inductive sequence. Provisional categories were derived a priori to reflect core level one motivators in the model and were refined through iterative review into a six-category codebook. The focal open response prompt asked students whether they ever hesitate to ask a parent for help when they need assistance with a math task. Five categories captured barriers reported by students who indicated hesitation: (1) emotional concerns, (2) student autonomy orientation, (3) parent knowledge & skill limits, (4) parental time limits, and (5) access to external supports. A sixth category, (6) no hesitation to ask, captured the perceived absence of a barrier among students who selected no hesitation, and described why they would reach out. Operational definitions and illustrative student responses are provided in Table 1. Categories were defined to be mutually exclusive and collectively exhaustive at the response level. A total of 123 valid responses were retained after excluding invalid entries. Two researchers applied the finalized definitions to the full corpus, achieving an intercoder agreement of 92.65%, which indicates strong reliability. Code frequencies were then compared across socioeconomic groups to identify convergences and contrasts.

Table 1: Theoretical Categories, Emergent Themes, Definitions, and Student Response

Theoretical Category	Emergent Theme	Operational Definition	Example Student Response
Personal motivators	Emotional concerns	Students anticipate or describe negative affect when asking parents for help.	"I am afraid I will be scolded."
Contextual motivators	Student autonomy orientation	Students prefer to solve problems independently.	"I want to figure it out by myself."
Contextual motivators	No hesitation to ask	Students state an unqualified willingness to seek help from parents.	"I would ask without hesitation."
Family life context: knowledge & skills	Parental knowledge & skill limits	Students perceive that parents lack sufficient mathematical knowledge or ability to provide help.	"My parents do not know math."
Family life context: Time & energy	Parental time limits	Students report that parents are too busy, tired, or unavailable to provide help.	"My parents are busy."
Family life context: Social capital	Access to external supports	Students rely on alternative academic supports (e.g., tutors, online resources, etc.).	"I can ask my private tutor."

Note. Theoretical categories are adapted from the Hoover-Dempsey and Sandler Model of the Parent Involvement Process.

Researcher positionality was considered as part of analytic rigor given the interpretive nature of qualitative analysis. The primary analyst is a mathematics education researcher with professional experience working with Korean elementary students and a sustained interest in equity in home-based learning supports. To limit the influence of any single perspective, the

qualitative analysis was guided by a priori theoretical framework, with operational definitions specified in a codebook. A second trained coder independently applied the finalized categories to the full corpus, and disagreements were resolved through discussion using explicit decision rules.

Quantitative analysis. Because several subgroup sizes were small, nonparametric tests were used. Group differences in frequencies were examined with chi-square test, Fisher's exact tests, and achievement differences were tested with Mann–Whitney U and the Kruskal–Wallis H tests with Dunn's post hoc comparisons using Bonferroni adjustment.

Sample and Procedure

With the consent of students and their caregivers, students were invited to complete an online survey to answer questions about their basic information (e.g., age, gender, ethnicity, and school), mathematics tutoring, help-seeking preferences, and the detailed reasons for either asking for or not asking for help. A total of 133 students responded to the survey, and 123 students completed the survey, yielding a 92.48% complete response rate. The participants were 6th grade elementary school students whose age range between 11 and 12 years old. The decision on participants' grade was guided by Crystal et al. (2008) in that 6th grade students showed higher tendency to seek help on their homework compared to other higher-grade students.

The study solicitation targeted variation in students' family SES. Because direct questions about parental income, occupation, assets, or consumption are culturally sensitive in Korea (Kim et al., 2019), recent work has favored simplified SES indicators (Valero et al., 2015). Aggregate indices at the school or neighborhood level are commonly used (Kim et al., 2019). For this study, data from the Korean Statistical Information Service (KOSIS) is releasing tax payment information by city, county, and district every year, which allowed calculation of per capital income as a core SES indicator (Wani, 2019). Using these data, the 25 districts in Seoul was ranked by mean SES, and 10 schools were selected in eight districts, with three in higher income areas and five in lower income areas.

A mathematics achievement test was administered alongside the survey questionnaire. The test consisted of 20 problems to be solved within a 40-minute time frame, reflecting a traditional standardized testing setting in South Korea. Because the testing instrument covered the majority of the mathematics curriculum for the first half of the school year, classroom teachers who assisted with survey distribution also supported test administration for the entire class for instructional purposes. Students solved the problems directly on the test sheets, and only the sheets completed by study participants were collected separately and forwarded to the researchers for further analysis.

Instrument

Help-seeking behavior. An eight-item survey was developed to capture students' mathematics help-seeking preferences, with open ended prompts designed to elicit students' reasons for asking for or refraining from parental help. The focal item asked whether students hesitated to ask a parent for math help and requested a brief explanation aligned to the Yes or No response, capturing either reasons for hesitation or motivations for reaching out.

Mathematics achievement. The testing instruments were developed by adapting problems from as a basic academic skill assessment and a 6th grade summative assessment created by the Ministry of Education, and i-Scream, respectively. The i-Scream is a private teaching supporting platform where 93% of elementary teachers use (Jang, 2025). Twenty multiple-choice items were included in the achievement test, and the breadth of the problems was designed to cover all topics specified in the national curriculum for the first

half of the academic year. Both the achievement testing instrument and its administration were valid in that it followed the norm of traditional summative achievement testing applied to many elementary classrooms (Lee, 2009). The content domains included fraction operations, three-dimensional geometry and measurement, ratio and proportion, and data analysis.

Results

Descriptive Analysis

Data from 133 students were analyzed to examine parental math help-seeking and mathematics achievement. The high SES (n = 51) and low SES (n = 82) groups had similar gender distributions. The high SES group included 26 boys and 25 girls, and the low SES group included 40 boys and 42 girls.

Tutoring participation differed substantially by SES. Most high SES students reported tutoring (80.4%), whereas nearly half of low SES students did not (46.3%). Gender was not associated with tutoring participation in either the high SES group (r = .089, p = .534) or the low SES group (r = .121, p = .281). Achievement analyses using Mann Whitney U tests showed that high SES students scored higher than low SES students (z = −3.75, p < .001), and students who participated in tutoring scored higher than those who did not (z = 3.20, p = .001), while gender differences were not significant (z = .732, p = .464). Within group follow up Mann-Whitney U tests indicated that the tutoring advantage was concentrated in the low SES group (z = 2.49, p = .013) and was not significant among high SES students (z = .872, p = .383).

Content Analysis

Content analysis revealed clear differences by socioeconomic status. Across groups, no hesitation was the model theme. It accounted for 69.4% of coded instances among high SES responses and 64.9% among low SES responses, often phrased as “I would ask without hesitation.” In contrast, barrier themes clustered in the low SES group. Parental knowledge and skill limits comprised 18.2% of low SES codes compared with 6.5% in high SES, typically expressed as “My parents do not know math.” Emotional concerns comprised 10.4% in low SES and 4.3% in high SES, with wording such as “I am afraid I will be scolded.” Student autonomy orientation appeared at low levels in both groups (6.5% in high SES; 3.9% in low SES), indicating some preference to solve problems independently. Parental time limits and access to external supports were infrequent in both groups, each at about 5% or less. Theme distributions within each SES group are summarized in Tables 2 and 3.

Table 2: High SES - Frequency and Percentage of Reported Help-Seeking Categories

Ranking	Categories	Code Counts	Percentage
1	No hesitation to ask	34	69.4
2 (tied)	Parental knowledge & skill limits	3	6.5
2	Student autonomy orientation	3	6.5
4 (tied)	Emotional concerns	2	4.3
4	Parental time limits	2	4.3
4	Access to external supports	2	4.3
Total		46	100.0

Table 3: Low SES - Frequency and Percentage of Reported Help-Seeking Categories

Ranking	Categories	Code Counts	Percentage
1	No hesitation to ask	50	64.9
2	Parental knowledge & skill limits	14	18.2
3	Emotional concerns	8	10.4
4	Student autonomy orientation	3	3.9
5 (tied)	Parental time limits	1	1.3
5	Access to external supports	1	1.3
Total		77	100.0

Taken together, the pattern indicates that many students view parents as a viable resource, but knowledge based and emotion-based barriers are reported more often by students from low SES backgrounds, whereas high SES responses are less concentrated in any single barrier theme. At the same time, a Pearson chi-square test comparing the distribution of the six coded themes across SES groups was not statistically significant, $x^2(5, N = 123) = 7.068$, $p = .21$. The six-theme distribution did not differ significantly by SES, likely due to sparse cells and a high base rate of no hesitation. A sensitivity check excluding no hesitation remained non-significant. Because chi-square tests can be unreliable with low expected frequencies, responses were aggregated into a dichotomous indicator, "no hesitation" versus "hesitation." This aggregation reduced table sparsity and provided a more reliable test of whether the propensity to hesitate differs by SES. Under this dichotomization, the chi-square test indicated a statistically significant association $x^2(1,123) = 4.575$, $p = .032$, and a Fisher exact test was conducted as a robustness check given small expected counts ($p = .025$). Both tests supported the interpretation that SES is associated with whether students report hesitation to ask parents. Building on this, subsequent analyses examined whether the achievement gap varies across SES by hesitation status using the Kruskal Wallis H test following by Dunn's method with a Bonferroni correction.

Kruskal Wallis H Test and Dunn's Method with a Bonferroni Correction

Kruskal-Wallis H tests indicated statistically significant differences in students' mathematics achievement across four subgroups defined by SES and parental help-seeking hesitation, $x^2(3, N = 123) = 19.432$, $p < .001$. Mean ranks of mathematics achievement were highest for the high SES with no hesitation (79.16), followed by high SES with hesitation (72.50), low SES with hesitation (65.43), and low SES with no hesitation (45.96). Dunn post hoc comparisons showed that the low SES with no hesitation subgroup scored lower than the other groups, but after Bonferroni adjustment only the difference between high SES with no hesitation remained significant ($p < .001$). Table 4 presents the pairwise comparisons of the four groups' mean ranks in mathematics achievement.

To explore additional factors associated with mathematics achievement within the low SES group, a follow-up analysis incorporated private tutoring participation. Low SES students were classified into four subgroups: (1) Hesitation × Tutoring, (2) Hesitation × No Tutoring, (3) No Hesitation × Tutoring, and (4) No Hesitation × No Tutoring, and mathematics achievement was compared using a Kruskal Wallis H test.

Table 4: Pairwise Comparison of SES X Help Hesitation

Group1 / Group2	Test	Std. Error	Sig.	Adj. Sig.
Low SES × No Hesitation / Low SES × Hesitation	19.466	8.483	.022	.131
Low SES × No Hesitation / High SES × Hesitation	26.540	11.418	.020	.121
Low SES × No Hesitation / High SES × No Hesitation	33.202	7.896	<.001	.000
Low SES × Hesitation / High SES × Hesitation	7.074	12.324	.566	1.000
Low SES× Hesitation / High SES × No Hesitation	13.736	9.156	.134	.801
High SES × Hesitation / High SES × No Hesitation	–6.662	11.927	.576	1.000

Achievement differed statistically significantly across the four subgroups, $x^2(3, N = 77) = 11.698$, $p = .008$. Mean ranks of mathematics achievement were highest for hesitation with tutoring (53.86), followed by no hesitation with tutoring (38.02), hesitation with no tutoring (35.11), and no hesitation with no tutoring (30.96).

Dunn post hoc comparisons indicated that no hesitation with no tutoring was statistically significantly lower than that for hesitation with tutoring ($p < .001$), and this difference remained statistically significant after Bonferroni correction ($p = .005$). These results suggest that, within the low SES group, students with tutoring, particularly those who also reported hesitation in seeking parental help, demonstrated higher mathematics achievement that students who had neither tutoring nor hesitation. Table 5 presents the pairwise comparisons of the four groups' mean ranks in mathematics achievement.

Table 5: Pairwise Comparison of Help Hesitation X Tutoring

Group1 / Group2	Test	Std. Error	Sig.	Adj. Sig.
No Hesitation × No Tutor / Hesitation × No Tutor	4.150	8.622	.630	1.000
No Hesitation × No Tutor / No Hesitation × Tutor	7.059	6.311	.263	1.000
No Hesitation × No Tutor / Hesitation × Tutor	22.900	6.836	<.001	.005
Hesitation × No Tutor / No Hesitation × Tutor	–2.910	8.714	.738	1.000
Hesitation × No Tutor / Hesitation × Tutor	18.750	9.102	.039	.236
No Hesitation × Tutor / Hesitation × Tutor	15.840	6.951	.023	.136

Discussions and Conclusions

This study is important to mathematics education by challenging the assumption that more help-seeking is necessarily better and by offering a framework for interpreting student hesitation as a contextual signal rather than a deficit. Across the full sample, achievement differences by SES remained evident even among students who reported no hesitation to ask parents, suggesting that willingness to seek help does not equalize opportunity to learn. Within the low SES group, patterns by hesitation status further indicated that the meaning of hesitation may differ across social contexts. In this setting, refraining from asking parents was not necessarily a marker of disengagement. Instead, it may reflect a realistic appraisal of the costs and benefits of asking at home.

The content analysis provides an important interpretive anchor for these patterns. Low SES students who hesitated more often described parental knowledge and skill limits and concerns

about negative emotional reactions. These themes point to two intertwined constraints. One is instructional, in that parents may not be able to explain current mathematics content or strategies in ways students find usable. The other is relational, in that help-seeking may carry emotional risk, such as fear of being scolded or of increasing stress at home. In contrast, high SES responses were less concentrated in any single barrier theme and more frequently reflected an absence of hesitation, consistent with a home context in which asking is experienced as feasible and emotionally safe.

The follow up analysis within the low SES group investigates the role of the broader support ecology, particularly access to private tutoring. Achievement differed significantly across four subgroups defined by hesitation and tutoring, with the strongest performance observed among students who had tutoring and reported hesitation, and the lowest performance among students who had neither tutoring nor hesitation. In this sense, reliance on parental help in the absence of accessible alternatives may be a vulnerable configuration for some low SES students, not because parents are unwilling to help, but because the support available at home may be constrained in content knowledge, time, or emotional climate.

These results suggest that the function of hesitation is shaped by the options students perceive as available. For students with tutoring, hesitation to ask parents may reflect strategic allocation of help-seeking toward sources viewed as more reliable or less emotionally costly. For students without tutoring, reporting no hesitation may not indicate stronger support; it may instead reflect the absence of other viable pathways, leaving students dependent on home help that may not consistently promote understanding. This interpretation aligns with sociocultural perspectives that treat help-seeking as relational and situated, shaped by norms, resources, and interactional histories rather than by individual disposition alone.

Implications for Practice

From a practice standpoint, the findings argue against interventions that focus only on increasing the frequency of parental involvement. What appears to matter is not simply whether children ask, but whether the help they can access is instructionally useful and emotionally safe. Two complementary levers follow.

First, family facing supports can strengthen parents' capacity to assist in ways that do not require advanced content expertise. Schools can share short routines that promote constructive help interactions, such as prompting children to explain their thinking. These routines also address emotional climate by reducing judgment and conflict during math talk. Second, schools and communities should expand reliable non-parent pathways for assistance, especially for students who cannot depend on private tutoring. Structured opportunities such as homework clubs and teacher office hours can provide alternative routes that reduce the stakes of home-based help and support students' right to seek assistance when needed.

Conclusion and Future Directions

Overall, this study highlights that equity in mathematics learning involves more than encouraging children to ask for help. It requires attention to the social and emotional conditions that make help-seeking possible and productive, and to the distribution of support pathways across contexts. Future research should examine these mechanisms with designs that capture the quality of help interactions and the availability of alternative supports, and that follow students over time to clarify how help-seeking pathways develop across home, school, and community settings.

"FINALLY TAKING A STEP BACK": MATHEMATICS CO-TEACHERS' POWER NEGOTIATIONS AND KNOWLEDGE EXCHANGES DURING CO-PLANNING

Lauren Rigby
University of Texas at Austin
laurenrigby@utexas.edu

Students with disabilities are often denied meaningful opportunities for mathematical sense-making (Lambert & Tan, 2017). Co-teaching between mathematics teachers and special educators offers a promising approach for disrupting these inequities by leveraging complementary expertise from both fields. Grounded in Fairclough's (2003) critical discourse framework and Disability Studies in Mathematics Education scholarship, this qualitative study draws on a video-recorded co-planning session and semi-structured interviews with one mathematics co-teaching pair to examine how power and expertise are negotiated through discursive moves. Findings show that co-teachers enacted, shared, and resisted power while crossing boundaries between fields, positioning co-planning as a key site for reconfiguring authority and negotiating distinct expertise to better support mathematical sense-making.

Keywords: Special Education, Students with Disabilities, Teacher Knowledge

Current mathematics education reforms and policies emphasize that all students should have opportunities for mathematical sense-making, defined as opportunities to develop conceptual and procedural understanding through engagement with grade-level content connected to students' lived experiences (National Council of Teachers of Mathematics [NCTM], 2018; NCTM & Council for Exceptional Children [CEC], 2024). Yet, despite these policy commitments, students with disabilities continue to be denied such opportunities in K–12 mathematics classrooms. In their analysis of 149 articles, Lambert and Tan (2017) found that mathematics instruction for students with disabilities frequently prioritizes procedural compliance and remediation over sense-making, reinforcing deficit views of disability and mathematical competence.

Co-teaching between mathematics teachers and special educators who co-plan, co-deliver, and co-assess general instruction has been identified as a promising approach for addressing these inequities. Co-teaching brings together distinct yet complementary forms of expertise, including knowledge of mathematics teaching and knowledge of accommodations for individual learners, which can be used to leverage opportunities for mathematical sense-making for all students in general education settings, including students with disabilities (e.g., Lambert & Tan, 2016; Sheppard & Wieman, 2020; Cohen et al., 2025). However, mathematics and special education have long operated in disciplinary silos, with limited collaboration and persistent tensions rooted in differing learning perspectives, conferences, journals, and teacher preparation pathways (Schwartz, 2023; Cohen et al., 2025). These structural divisions are often accompanied by unbalanced power dynamics at both institutional and interpersonal levels.

Within collaborative settings such as co-taught classrooms, co-planning sessions, and professional learning communities, co-teachers position themselves and each other into particular roles through discursive interactions that negotiate power (Davies & Harré, 1990). Prior research suggests that these negotiations frequently reproduce hierarchical relationships. For example, Zigmond and Matta (2004) observed 41 pairs of high school co-teachers across subjects and found that mathematics teaching was generally dictated by the mathematics teacher while the special educator was positioned as a "helper." In such arrangements, power is enacted rather than shared, limiting the potential for collaboration and integrated expertise.

At the same time, co-planning contexts open up opportunities for boundary crossing, interactions across historically distinct professional domains (Engeström et al., 1995; Akkerman & Bakker, 2011). Akkerman and Bakker (2011) argue that educational boundaries necessitate dialogue through which participants negotiate meaning. Through this dialogue, co-teachers may exchange forms of knowledge not traditionally associated with their disciplinary roles, disrupt siloed practices, and collaboratively problem solve around instruction. Despite this potential, there is a need to better understand how mathematics and special education co-teachers navigate tensions, negotiate power dynamics, and exchange expertise through discourse. The purpose of this study is to explore how mathematics and special education co-teachers use discursive interactions during co-planning sessions to negotiate power and exchange knowledge, with the goal of understanding how collaborative dialogue can support integration of expertise across fields and disrupt disciplinary siloes. This study is guided by the following research question: *How does a collaborative mathematics co-teaching pair exchange knowledge and negotiate power through discursive interactions during co-planning?*

Theoretical Framework and Literature Review

Disability Studies in Mathematics Education

This study draws from the field of Disability Studies in Mathematics Education (DSME) that advances a social model of disability. From a social model perspective, disability is produced through classroom structures, instructional practices, and institutional norms that shape whose mathematical thinking is validated and supported. Accordingly, DSME scholarship foregrounds how students' opportunities for mathematical sense-making are constructed within mathematics classrooms rather than predetermined by disability labels (e.g., Tan & Kastberg, 2017; Lambert & Tan, 2020; Tan et al., 2022; Yeh et al., 2024). Central to this perspective is the claim that structures, processes, and learning environments—rather than individual students—must be primary sites of change, as all learners, disabled or not, are capable of engaging in mathematical sense-making when provided meaningful and equitable opportunities (Lambert & Tan, 2017).

This study builds from a growing body of research that documents the mathematical competence of students with learning disabilities, autism, intellectual disabilities, and/or visual impairments (e.g., Eriksson, 2008; Fernandes & Healy, 2013; Figueiras & Arcavi, 2014; Hunt & Empson, 2015; Göransson et al., 2016; Lewis & Fisher, 2016; Tan et al., 2019; Lambert et al., 2020; Yeh et al., 2020; Wilson & Hunt, 2022; Shi, 2024). Collectively, this scholarship demonstrates that students labeled as disabled can learn and do mathematics when learning environments are designed to support sense-making.

While DSME scholars have primarily focused on supporting students' sense-making from the lens of changes within the learning environment, there is a need to extend this perspective to the environments in which teachers collaboratively design instruction. This study addresses this gap by exploring the co-planning environment of a mathematics co-teaching pair, focusing on how teachers draw on and negotiate their distinct expertise to support mathematical sense-making. By shifting analytic attention from students alone to teachers' collaborative spaces, this work extends DSME's social model of disability to mathematics co-teaching practices itself.

Fairclough's Conceptualization of Power

This study specifically studies power dynamics between co-teaching pairs. As such, this study draws on key aspects of Fairclough's (2003) framework for analyzing spoken and written language, with particular attention to his conceptualization of power, to examine the co-teachers' discursive interactions during mathematics co-planning. Fairclough (2003) defines *power* as the ability to secure a particular outcome even if the outcome depends on the agency of others. From

this perspective, power is not static or individually possessed but is enacted, shared, or resisted through discursive interactions as individuals negotiate the meanings of social practices, relationships, and identities.

In this study, the co-teachers negotiate power through discursive moves as they exchange knowledge while co-planning instruction. These power negotiations occur within knowledge exchanges, where knowledge is shared or elicited, and determine whether the co-teachers' decisions are made collaboratively or one teacher's perspective is privileged over the other.

Domains of Teacher Knowledge

Teacher education research has introduced many frameworks for conceptualizing teacher knowledge. Shulman (1986) introduced pedagogical content knowledge as knowledge of how to teach a particular subject matter. Building from Shulman's work, Grossman (1990) conceptualized teacher knowledge as encompassing four domains: subject matter knowledge (i.e., knowledge of mathematics), pedagogical knowledge (i.e., knowledge of learning, learners, and classroom management), knowledge of context (i.e., knowledge of individual students, school setting, and community), and pedagogical content knowledge (i.e., combination of subject matter, pedagogical, and context knowledge).

Notably absent from these frameworks is the specialized knowledge required to differentiate, accommodate, scaffold, and assess instruction for individual learners (Brownell et al., 2010; CEC, 2022). I refer to this domain as *knowledge of individualized education*. The longstanding separation between mathematics education and special education has resulted in mathematics teachers often lacking knowledge of individualized education, while special educators frequently lack pedagogical content knowledge for teaching mathematics (Lambert & Tan, 2017, 2020; Cohen et al., 2025). For mathematics co-teaching to meaningfully support diverse learners, it is therefore critical that co-teachers exchange and integrate these complementary domains of knowledge through collaborative planning.

Methods

Context and Participants

Situated within a larger qualitative case study examining collaborative mathematics co-teaching practices, this exploratory case study focuses on one mathematics co-teaching pair in a micro-urban community in Midwestern United States. At the time of data collection, Thomas (pseudonym), the general education mathematics teacher, and Elizabeth (pseudonym), the special educator, were identified by a leader of the North American Chapter of the International Group for the Psychology of Mathematics Education's (PMENA) Disability Studies in Mathematics Education Working Group as successful collaborators. They were in their second year of co-teaching together and jointly taught a general 9th grade Algebra I class aligned with grade-level standards.

Elizabeth identifies as a White, female Special Education Learning Behavior Specialist in her second year of teaching and co-teaching. Thomas identifies as a White, male mathematics teacher with a master's in Curriculum and Instruction, 29 years of teaching experience, and 22 years of co-teaching experiences. Their co-taught Algebra I class consists of 21 students, including five students who qualified for special education services in mathematics. The two participants shared responsibility for planning and teaching daily math instruction for all students in the class. During their interviews, both teachers claimed that co-planning was a central feature of their collaboration. Elizabeth and Thomas met weekly every Tuesday for an hour during Thomas's prep period and Elizabeth's hall duty period. They also engaged in co-planning during "found" time throughout the school week (e.g., between classes, during lunch, after school).

Their high school serves approximately 1,000 students. The student population is 33% Black, 25% Hispanic, and 25% White, with 15.9% of students receiving special education services. In one of his interviews, Thomas shared that the school had previously implemented co-teaching models. He also explained that school leadership has recently prioritized strengthening mathematics co-teaching in response to rising failure rates among ninth grade students with disabilities in Algebra I. As part of this initiative, a mathematics co-teaching instructional coach has been co-teaching with math teachers for the past two years—a form of support that both Elizabeth and Thomas identified in interviews as critical to their co-teaching practice.

Data Collection and Analysis

This study employs multiple data collection methods to examine the co-teachers' discursive interactions. Data collection included (a) a video-recorded co-planning session in which participants jointly planned a mathematics lesson; (b) a self-recorded video observation of the co-teaching of that same lesson; (c) individual video-elicited cognitive interviews (Dempsey, 2010); and (d) individual semi-structured interviews. During the video-elicited interviews, each teacher viewed segments of the recorded lesson and paused as needed to reflect on their instructional decisions, co-teaching processes, and interpretations of their partner's contributions. The semi-structured interviews were designed to elicit teachers' perspectives on the broader sociocultural context of their co-teaching, including their collaborative partnership, institutional structures, and other factors that influence their mathematics co-teaching.

All data were transcribed using Zoom's automated transcription tool and subsequently I edited each one for accuracy. I began analysis by segmenting the co-planning transcript into *exchanges*, defined by Fairclough (2003) as a sequence of two or more conversational moves with alternating speakers. At its simplest, an exchange follows a pattern of *Initiation-Response-Follow-up* (Fairclough, 2003), though exchanges can also involve extended, more nuanced sequences of these conversational moves. Each exchange served as the unit of analysis.

Knowledge exchanges. After segmenting the data into exchanges, I used Fairclough's (2003) framework to categorize each exchange as either knowledge exchanges or activity exchanges, based on whether the interaction involved eliciting or sharing knowledge, or coordinating actions and tasks. Because this study focuses on how co-teachers negotiate power and exchange knowledge through discourse, only knowledge exchanges were retained for subsequent phases of analysis.

Drawing on Fairclough (2003), I identified how each knowledge exchange was initiated. Knowledge exchanges can be initiated by either the mathematics teacher (MT) or the special educator (SE), who assumes the role of either the *knower* (sharing information) or the *other* (eliciting information). Each knowledge exchange was coded with the type of initiation (MT Knower, SE Knower, MT Other, or SE Other). I then characterized the type of teacher knowledge exchanged by the co-teachers by drawing on Grossman's (1990) generalized framework of teacher knowledge, supplemented by knowledge of individualized education (Brownell et al., 2010; CEC, 2022). I coded each knowledge exchange according to the type of knowledge(s) shared or elicited: subject matter knowledge, pedagogical knowledge, knowledge of context, pedagogical content knowledge, or knowledge of individualized education.

Power negotiations. Throughout their co-planning session, the co-teachers negotiated power through discursive moves embedded within knowledge exchanges, resulting in the co-teachers enacting, sharing, and/or resisting power (Fairclough 2003). These power negotiations can either inhibit or facilitate each co-teacher's ability to contribute knowledge and influence decision-making. To analyze how the co-teachers negotiated power during co-planning, I engaged in

Saldaña's (2021) process of deductive coding, in which power negotiation codes (i.e., enact power, share power, resist power) were pre-determined and used in a top-down approach to analyze the co-planning data. Building from Fairclough's work (2003, 2015), Table 1 provides examples of how power negotiations could be manifested in the co-teachers' dialogue during co–planning and was used to guide the coding of power negotiations.

Table 1: Examples of Discursive Moves Used to Negotiate Power

Power Negotiation	Discursive Moves	Examples
Enacting Power	Controlling agenda/topic	"Next, we'll talk about…"
	Giving commands/directives	"The quiz will have ten questions."
	Strengthening authority	"We must…"
	Closing discussion	"Okay. We'll do this."
	Interrupting	"So maybe if we do…"
Sharing Power	Negotiating agenda/topic	"Should we discuss the quiz next?"
	Making decisions jointly	"So we both agree that…"
	Softening authority	"I think it might be best if…"
	Building on each other's ideas	"What do you think?"
Resisting Power	Rejecting agenda/topic	"No, I think we should…"
	Challenging commands/directives	"I actually think it went well."
	Ignoring/changing topic	"I'm going to look at the review."
	Reopening discussion	"Can we circle back to…"
	Questioning ideas	"Is that too many problems?"
	Joking/storytelling	"Did you hear about yesterday?"
	Asserting knowledge	"In my experience…"

For each knowledge exchange, power could be enacted, shared, and/or resisted by either the mathematics teacher (MT) or the special educator (SE). As such, I further categorized the power negotiation codes to indicate which co-teacher used discursive moves to negotiate power during the exchange: MT Enacting Power, MT Resisting Power, Sharing Power, SE Resisting Power, and SE Enacting Power. Since the co-teachers could concurrently negotiate power through discursive moves in a single knowledge exchange, power negotiation codes were not discretely applied, meaning each knowledge exchange could have multiple power negotiation codes assigned to it (e.g., MT Enacting Power & SE Resisting Power).

Validity. To ensure the trustworthiness of the study, several strategies were employed: rich and thick description of the case, working with a peer debriefer who reviewed interpretations, and member checking with the co-teachers to confirm that the interpretations accurately reflected their experiences (Erlandson et al., 1993). Interview data were also used to triangulate findings and support interpretations of the co-teachers' discursive interactions during co-planning.

Results

Positioning Expertise through Knowledge Exchanges

Thomas, the general mathematics teacher (MT), and Elizabeth, the special educator (SE), engaged in 95 knowledge exchanges during their 40-minute co-planning session (see Table 2). Thomas initiated 72 (75.8%) exchanges while Elizabeth initiated 23 (24.2%), suggesting that Thomas more frequently set the agenda and steered the direction of the talk. In this sense,

Thomas shaped the terms of knowledge exchange by determining when exchanges began, what knowledge was made relevant, and how participation was structured.

Table 2: Knowledge Exchanges by Initiation Type

Number of Exchanges Initiated	MT Knower	MT Other	SE Knower	SE Other	Total
Knowledge Exchanges	33	39	15	8	95

At the same time, the type of Thomas's initiations complicates a straightforward interpretation of Thomas's power throughout the co-planning session. Of the 72 exchanges Thomas initiated, 33 involved sharing his own knowledge, while 39 involved eliciting Elizabeth's knowledge (see Table 2). Of the latter instances, Thomas was explicitly orienting Elizabeth as the source of expertise by inviting her contributions into the interaction. Correspondingly, across all exchanges, Thomas was positioned as the knower in 41 exchanges (43.2%) whereas Elizabeth was positioned as the knower in 54 exchanges (56.8%). Although Thomas more often initiated exchanges and directed the flow of the meeting, Elizabeth was more often positioned as the knower within these interactions. This configuration of interaction stands in contrast to prior research, where special educators are often positioned primarily as implementers rather than contributors to instructional decisions (Zigmond & Matta, 2004).

Boundary Crossing through Knowledge Exchanges

During their co-planning session, Thomas and Elizabeth engaged in knowledge exchanges related to specialized areas of teacher knowledge within both mathematics and special education. Of the 11 knowledge exchanges involving knowledge of individualized education, Thomas was positioned as the knower in five (45.5%; see Table 3). Of the 42 knowledge exchanges involving pedagogical content knowledge, Elizabeth was positioned as the knower in 25 (59.5%). The frequent positioning of each co-teacher as the knower in an area of teacher knowledge not traditionally associated with their disciplinary role suggests that the co-teachers engaged in boundary crossing between disciplines and disruption of disciplinary siloes during their co-planning session. As both co-teachers commented in their interviews, this boundary crossing provides space for the co-teachers to learn with and from each other.

Table 3: Knowledge Exchanges by Initiation Type and Knowledge Type

Knowledge Type	MT Knower	MT Other	SE Knower	SE Other
Subject Matter Knowledge (SMK)	0	0	0	0
Pedagogical Knowledge (PK)	13	15	3	3
Knowledge of Context (KC)	0	1	2	0
Pedagogical Content Knowledge (PCK)	12	19	6	4
Knowledge of Individualized Education (KIE)	3	4	2	1
KIE & PCK	1	0	0	0
PK & KC	4	0	1	0

Across exchanges involving pedagogical content knowledge, Thomas more frequently initiated interactions that elicited Elizabeth as the knower (19) than those in which he positioned

himself as the knower (12). These exchanges often focused on instructional decisions at the intersection of mathematical content and responsiveness to students' learning needs. For example, when creating a quiz to determine topics for review before the upcoming test, Thomas repeatedly solicited Elizabeth's input on which mathematics topics should be included, how many items should be allotted for each topic, and whether the proposed structure provided sufficient support for students' learning, positioning Elizabeth as an expert in pedagogical content knowledge.

During their individual social network interviews, both co-teachers described changes in their professional learning over time. Elizabeth reflected on her initial uncertainty with subject matter knowledge and pedagogical content knowledge during her first year of teaching. She noted that her confidence in and knowledge of math teaching developed through ongoing collaboration with Thomas. Thomas similarly described a shift in his perspective of the value of a special education co-teacher. He emphasized Elizabeth's desire to be "an equal teacher" and her willingness to engage in shared learning. He reported that these experiences helped him to make a conscious choice to rely on and value Elizabeth's expertise during instruction and planning.

While Elizabeth positioned Thomas as a source of expertise in knowledge related to individualized education in only one exchange, Thomas positioned himself as a knower in this area on four occasions. For example, near the conclusion of the co-planning session, Thomas initiated a knowledge exchange to summarize the teaching models and multi-modal supports incorporated in their lesson design. In this exchange, Thomas drew on knowledge associated with individualized education, crossing the boundary between mathematics and special education. In an interview, Thomas noted that in the past he struggled with supporting the mathematical learning of his students with disabilities but has developed greater knowledge of instructional adaptations through collaboration with Elizabeth. This perspective was echoed by their mathematics co-teaching instructional coach, who was paraphrased by Elizabeth in her social network interview as saying, "You really have pushed Thomas. Like, I never would have thought I would see these things so late in his career. He's really doing great as a co-teacher."

Negotiating Power through Discursive Moves

As the co-teachers engaged in knowledge exchanges, they used discursive moves to enact, share, or resist power (see Table 1). Consistent with prior research suggesting that mathematics teachers often occupy positions of authority in co-teaching partnerships (Zigmond & Matta, 2004), Thomas enacted power in 36 knowledge exchanges (37.9%), most frequently when initiating an exchange as the knower (see Table 4). However, a substantial proportion of the exchanges were coded as sharing power (45, 47.4%). This suggests that power was frequently negotiated rather than unilaterally exercised during co-planning.

The following exchange illustrates how Thomas and Elizabeth shared power as they collaborated to create contextual review problems for their lesson:

1	MT:	And I'm kind of mixing these up, and if you think that would be—do you
2		think if the kids see it that way, it's gonna mess them up? So they see $3
3		written out that way [3 dollars], the $2.50 in the other way [$2.50]? Is that
4		gonna freak…
5	SE:	Yeah, I don't like the "3 dollars". [Chuckles]
6	MT:	[Laughing] Do it! Change it! No, no, that's fine. But is that, like—Okay,
7		so we've got that, and your 2-liter bottle costs $2.50. Okay, cool.

In line 1, Thomas uses hedging ("I'm kind of…", "if you think that would be…") to open space for Elizabeth's feedback, positioning her as the knower on how students might interpret the

representation. Elizabeth's response in line 5 offers a clear evaluative stance, which is mitigated through laughter and functions as an affiliative move rather than a challenge. Thomas's immediate uptake and recommendation to make the change in line 6 signals alignment with Elizabeth's suggestion, even as he briefly continues negotiating the decision ("No, no, that's fine. But is that, like…"). Together, these discursive moves demonstrate how authority was dynamically and jointly negotiated and enacted within the interaction.

Table 4: Knowledge Exchanges by Initiation Type and Power Negotiation

Initiation Type	MT Enacting	MT Resisting	Sharing	SE Resisting	SE Enacting	MT Enacting to Sharing	MT Enacting and SE Resisting
MT Knower	22	0	7	0	1	1	2
MT Other	11	0	25	1	1	1	0
SE Knower	2	0	7	4	1	0	1
SE Other	1	0	6	0	1	0	0
Total	36	0	45	5	4	2	3

Conclusion

This study examined how a mathematics teacher and a special educator used discursive moves during co-planning to negotiate power and exchange knowledge. Analysis of their interactions shows that the mathematics co-teachers drew on distinct forms of expertise associated with their fields, while also crossing disciplinary boundaries to jointly develop instructional approaches designed to support students' mathematical sense-making, including those with disabilities. The co-teachers frequently engaged in discursive moves that shared power and functioned to redistribute authority across participants rather than consolidating it with a single speaker, thereby producing a more collaborative and negotiated co-planning space.

The frequency of shared-power exchange and boundary crossing highlights the importance of creating collaborative spaces in which co-teachers can share authority and draw on one another's expertise to inform instructional decisions. Implications for practice point to the need for dedicated co-planning time between mathematics co-teachers to facilitate the integration of complementary expertise from their fields. The study also highlights a need for professional learning that supports mathematics co-teachers beyond instructional strategies and includes collaboration strategies. Collaboration-focused professional learning is needed to support mathematical co-teachers in recognizing and using discursive moves to negotiate power and their distinct expertise to better support mathematical sense-making in their classrooms.

Reflecting on the partnership, Thomas described, "What you're seeing is the product of me finally taking a step back and not believing that I knew everything that I was doing, and a second year of working with somebody who helped me to do that in the first place." Such reflections underscore that expanding opportunities for mathematical sense-making for students with disabilities by improving mathematics co-teaching practices depends not only on instructional strategies, but also on how co-teachers structure their interactions, share authority, and learn with and from each other.

THEORIZING CULTURAL MATHEMATICAL CARING RELATIONS

Christopher O. Roman
Stockton University
christopher.roman@stockton.edu

This paper introduces a framework for cultural mathematical caring relations (CMCRs), an expansion of Hackenberg's (2005a) mathematical caring relations that explicitly acknowledges students' cultural and experiential realities. CMCRs integrate students' culture and interests into constructivist teaching experiments to support mathematical learning. Drawing from a teaching experiment with a developmental undergraduate student, Jocelyn, this paper illustrates how culturally relevant tasks can elicit meaningful reasoning about complex mathematical ideas such as intensity of change. By centering cultural relevance, CMCRs offer a pathway for cognitive researchers to challenge the status quo by attending to sociopolitical factors in their work.

Keywords: Cognition; Equity, Inclusion, and Diversity; Systemic Change

If you asked educators whether they care about their students, the vast majority would say that they do. Many enter the profession with a genuine desire to help students succeed, and students are more likely to succeed when they feel their teacher cares about them. After all, few students are motivated to work for someone they believe is uninterested in their needs or experiences. In the context of mathematics education, however, general care alone is not sufficient for supporting students' mathematical learning and development (Hackenberg, 2005b). A teacher may care deeply about students' interests, hobbies, academic success, or lives outside of school, but this does not necessarily translate into meaningful mathematical learning. This raises an important question: how can mathematics educators establish caring relationships that attend both to students' personal lives and needs, and to their mathematical learning?

Noddings (1984, 2002) defined caring relations as relationships that are grounded in care, and that involve two people: a carer (one-caring) and a cared-for. According to Noddings, the one-caring must experience *engrossment* and a *motivational displacement* when caring for the cared-for. Engrossment involves more than simply putting oneself in the shoes of the cared-for. Rather, the one-caring must receive the cared-for in a way that allows them to receive their feelings and feel with them. Motivational displacement, on the other hand, implies that the behaviors of the one-caring occur in service of the cared-for. Thus, the one-caring prioritizes the needs of the cared-for, even over their own needs. In turn, the cared-for must receive the care of the one-caring either with words or with indirect gestures, such as a smile or glow of happiness.

Noddings (1984) argued that the primary concern of all schools should be to maintain and enhance caring, but not at the expense of students' intellect. She emphasized that educators must attend to both caring and intellect. Yet her theory of care does not explicate how caring relations can be operationalized in a way that attends to both, particularly in a mathematical context.

Hackenberg (2005a) addressed this issue by operationalizing Nodding's caring relations in the context of a mathematical teaching experiment[1]. She defined a *mathematical caring relation* (MCR) "as a quality of interaction between a student and a mathematics teacher that conjoins affective and cognitive realms in the process of aiming for mathematical learning" (Hackenberg, 2010a, pp. 57–58). In other words, teachers aiming to establish MCRs seek to provoke learning

[1] A teaching experiment is a sequence of video-recorded teaching sessions, each involving a teacher-researcher, at least one student, and a witness-researcher (Steffe & Thompson, 2000).

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

by attending to students' mathematical ways of reasoning and emotional responses in the context of solving math tasks. Like general caring relations, MCRs cannot be established unless both the teacher and the student contribute to them in some way. Unlike general caring relations, however, MCRs require a commitment on the side of the carer (teacher) to provide the cared-for (student) with opportunities for mathematical learning.

Hackenberg's work involving MCRs (e.g., 2010a, 2010b) is unique because it lies in stark contrast to mathematics education research that has focused on how general caring by teachers impacts students' mathematical success (e.g., Hunter & Stinson, 2019). Yet this line of work is not without its limitations. Bartell (2011) noted that Hackenberg's research on MCRs "does not explicitly consider issues of race, culture, and power" (p. 55). That is, it does not explicitly attend to sociopolitical issues related to students from historically marginalized groups, and in particular, students of color.

This is problematic because MCRs are rooted in constructivist teaching experiments, which are grounded in uncovering and unpacking students' cognition. Given the privileged positioning of mathematical cognition within mathematics education research, cognitive studies have the potential to challenge dominant discourses in mathematics (e.g., formal mathematical knowledge serves as a proxy for intelligence) (Adiredja, 2021), as well as deficit discourses that negatively impact students from marginalized groups (e.g., Latinos do not value education) (San Miguel, 2011). Not attending to sociopolitical factors (e.g., culture, race), therefore, risks reinforcing the status quo such work seeks to disrupt.

The purpose of this theoretical paper is to respond to Bartell's (2011) critique by extending MCRs to more explicitly account for students' cultural and experiential realities in the context of constructivist teaching experiments. To do so, I introduce a framework for *cultural mathematical caring relations* (CMCRs). A CMCR is an MCR in which the teacher supports students' mathematical learning and development by engaging them in tasks that leverage their funds of knowledge. I define *funds of knowledge* as the knowledge and skills rooted in students' out-of-school experiences and interests, as well as their household and community culture (cf. Moll et al., 1992). I conceptualize *culture* as a dynamic construct, rather than a static collection of rituals, traditions, and customs. Thus, culture is constantly changing and dependent on the ways that individuals or households organize and respond to their experiences (González et al., 1995, 2001).

It is my hope that this paper will encourage cognitive researchers conducting teaching experiments to challenge the status quo by leveraging CMCRs to be more intentional about participant selection and to resist deficit framings by positioning students' cultural and experiential realities as assets for mathematical learning. In what follows, I unpack the framework for MCRs, extend it to CMCRs, and provide an example of a CMCR in action. I conclude by summarizing CMCRs and discussing their implications for cognitive research in mathematics education.

A Framework for Mathematical Caring Relations

Like caring relations, establishing MCRs is a two-way street. That is, MCRs cannot be completed unless both the teacher-researcher and the student contribute to them in some way. According to Hackenberg (2005a), from "a student's perspective, participating in mathematical caring relations involves being open to the teacher's interventions in the student's mathematical activity and pursuing questions and ideas of interest" (p. 4). Conversely, from the perspective of the teacher-researcher, establishing MCRs requires engagement in a three-step cyclical process: harmonizing with students' mathematical realities and affective responses, provoking learning,

and assessing and refining efforts to harmonize based on students' challenges.

Harmonizing with Students' Mathematical Realities and Affective Responses

Harmonizing with mathematical realities. According to Hackenberg (2010b), *harmonizing* "indicates that the teacher-researcher is monitoring interaction with students and making adjustments in response to the teacher-researcher's continually changing understanding about the students" (p. 242). The process of harmonizing with students' mathematical realities is intimately linked with the process of building second-order models of students' first-order mathematics. Students' *first-order mathematics* refers to "whatever might constitute students' mathematical realities" (Steffe & Thompson, 2000, p. 268). In other words, it encompasses the mathematical knowledge students have constructed and have at their disposal; it is "first-order" in that it pertains to their *own* mathematical knowledge.

Building second-order models, then, requires the teacher-researcher to document their interpretations of students' mathematical thinking and how they are experiencing the situation under observation (Steffe & Thompson, 2000). These models are "second-order" in that they are constructed from the teacher-researcher's understanding of students' mathematical knowledge. While second-order models can never be proven to depict students' true mathematical realities, they can, over a prolonged period of interaction, become more viable via testing for falsifiability. That is, the teacher-researcher can think of their model[2] as a hypothesis that can be proven false. If after testing the model it is proven to be false (i.e., falsified), then this would suggest that the model is not an appropriate fit for the student's experiential reality, and thus, must be refined by the teacher-researcher.

From the perspective of a teacher-researcher, cognitive decentering is critical in constructing viable models of their students' mathematical knowledge. I adopt Hackenberg's (2010b) definition of *cognitive decentering* as "the practice of setting one's own concepts to the side in order to formulate a coherent description of the mental activity of a student that can be the basis for interaction with that student" (pp. 239–240).

To harmonize with students' mathematical realities implies that the teacher-researcher engages in cognitive decentering to make sense of students' cognitive structures from their perspectives. The teacher-researcher must then create and pose tasks that students can engage with and that elicit the cognitive structures the teacher-researcher is attempting to evoke. Thus, the process of harmonization and the process of model building are intimately linked: harmonizing with students' mathematical realities supports the construction of viable models of students' mathematical knowledge, and these models, in turn, inform continued harmonization in future interactions.

Harmonizing with affective responses. Harmonizing with students' affective responses requires the teacher-researcher to monitor their students' levels of depletion and stimulation. I adopt Hackenberg's (2005a) definition of *depletion* as "a feeling of being taxed in some way" (p. 11), as well as her definition of *stimulation* as "a feeling of being excited or awake" (p. 12). The teacher-researcher must work to find the appropriate balance between their students' levels of depletion and stimulation; a small amount of depletion is healthy when students are confronted with challenging, yet manageable, math tasks, but a large amount of depletion can cause students to shut down completely (this might occur if a student feels that a task is out of their reach).

In her later work, Hackenberg (2010b, 2010a) leveraged the psychological construct of subjective vitality (Ryan & Frederick, 1997) to monitor students' energy levels. *Subjective vitality* refers to "the energy available to the self" (Ryan & Deci, 2008, p. 702) and is linked to a

[2] For convenience, I use the term "model" for the remainder of the paper.

person's affective experience. Connecting to depletion and stimulation, for instance, a high level of subjective vitality would correspond to a high level of stimulation, whereas a low level of subjective vitality would correspond to a high level of depletion. Thus, from the perspective of subjective vitality, harmonizing with students' affective responses implies making sure students' energy levels remain at equilibrium.

Subjective vitality depends on not only physical factors, but also mental factors (Ryan & Frederick, 1997). For example, a student who is working on a math problem can have low subjective vitality if they perceive the problem as crippling (i.e., damaging to their mathematical image or identity). Alternatively, they can have high subjective vitality if they perceive the situation as a surmountable obstacle that will make them more knowledgeable. An important note is that subjective vitality is not only associated with heightened levels of explicit excitement or stimulation, but also with calm energy (Thayer, 2001). Thayer describes *calm energy* as a state of high energy and low tension (i.e., stimulated, but relaxed). For instance, a student who is relaxed but mentally engaged with a math problem would be exhibiting calm energy, indicative of high subjective vitality.

Provoking Learning

The second step in establishing MCRs requires the teacher-researcher to provoke learning by providing their students with appropriately challenging math tasks. I define *learning* as a process that occurs when one makes a modification or refinement to their way of thinking. The word "provoke" is intended to convey that learning only needs to be initiated, not completed. Thus, the student does not need to experience learning for an MCR to be established; being appropriately challenged is sufficient.

To provoke learning, the teacher-researcher must harmonize with their students' mathematical realities and affective responses in just the right way. That is, they must pose mathematical tasks that are neither too easy nor too difficult, but appropriately challenging—tasks that support refinements to students' mathematical thinking while also maintaining or enhancing their energy levels.

Assessing and Refining Efforts to Harmonize Based on Students' Challenges

The final step in establishing MCRs requires the teacher-researcher to assess students' cognitive and affective responses to the challenges posed by tasks designed to provoke learning. Based on these assessments, the teacher-researcher adjusts the models of their students' mathematical knowledge—and, in turn, the tasks they pose—to improve harmonization with their students. The need to repeat this process of challenging and harmonizing is what makes the three-step process of establishing MCRs inherently cyclical.

Extending MCRs: A Framework for Cultural Mathematical Caring Relations

To extend MCRs to CMCRs, I draw on the theory of Culturally Relevant Pedagogy (CRP). Ladson-Billings (1995) defined CRP as a "pedagogy of opposition … specifically committed to collective, not merely individual empowerment" (p. 160). She developed CRP to promote the academic success of marginalized students, particularly African American students, by centering three key tenets: academic success, cultural competence, and critical consciousness.

Academic success involves supporting students in achieving success within dominant educational assessments, such as standardized tests and grades, while fostering students' intrinsic motivation for learning. Cultural competence requires teachers to incorporate students' diverse cultural backgrounds into instruction, not only to enhance their understanding of academic content, but also to deepen their appreciation of their own cultures and those of others. Critical consciousness demands that teachers recognize the sociopolitical and historical forces that shape

education and help students develop this awareness to analyze and challenge systemic inequities. By integrating these three tenets, CRP seeks to empower students both academically and socially, equipping them to navigate and transform the world around them.

CMCRs integrate MCRs with two of the three central tenets of CRP: academic success and cultural competence. Academic success is already central to MCRs, as their goal is to deepen students' mathematical knowledge through learning and development, with achievement defined in terms of individual cognitive growth. Cultural competence, however, is not explicitly addressed within MCRs. To integrate this critical tenet of CRP, the teacher-researcher must engage students with math tasks tied to their own or others' funds of knowledge, promoting a deeper appreciation of their own cultures and those of their peers. In this way, CMCRs not only support mathematical growth but also affirm students' cultural identities by recognizing their funds of knowledge as valuable resources in task design and instruction. Thus, CMCRs extend the three-step cyclical process of MCRs into a four-step cycle (see Figure 1) by explicitly incorporating students' funds of knowledge as an integral and recurring component of the caring process.

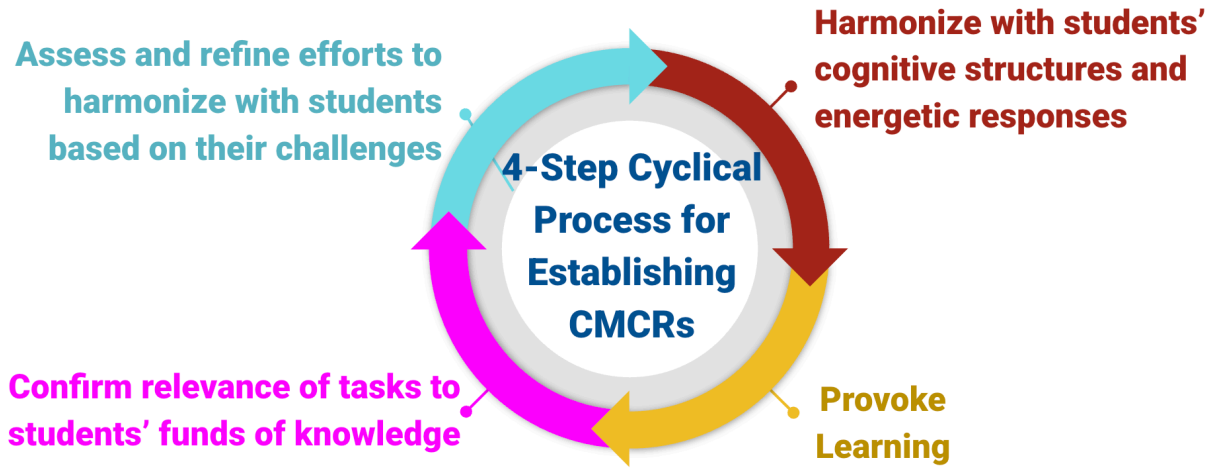

Figure 1: Four-Step Cyclical Process for Establishing CMCRs

Example of Establishing a CMCR

Background Information and Important Definitions

This example comes from a thirteen-session teaching experiment where I (Puerto Rican man) was the teacher-researcher, and my doctoral advisor (white man) was the witness-researcher. The aim of the teaching experiment was to showcase the rate of change development of two Latina undergraduate students, Yari and Jocelyn (pseudonyms), who were recruited from a developmental math course I taught in fall 2023. Jocelyn, a political science major who identifies as a white, Alaskan Native, and Puerto Rican woman, is the focal student in this example.

The eighth session of the teaching experiment, which is connected to this example, was conducted independently with Jocelyn due to a scheduling conflict. My primary goal during this session was to analyze how Jocelyn reasons about the intensity of change of an intensive quantity—an important component of rate of change reasoning. A *quantity* is a conception of a measurable attribute of an object (Olive & Çağlayan, 2008). An *intensive quantity* is a quantity that cannot be explicitly or directly measured, measures the *intensity*, or degree of presence of an

attribute (Stroup, 2002), and expresses a relationship between two quantities (Schwartz, 1988). For instance, the pinkness of a wall is an intensive quantity because it (1) cannot be directly measured with a ruler or scale, (2) measures the intensity of the wall's pinkness, and (3) can be expressed as a relationship between red and white paint.

To begin the session, I provided Jocelyn with a premade graph and asked her to connect it to her tea-making process at home. I chose to situate the task within a tea context because I had learned early in the experiment that tea was an important part of her household culture. The graph I provided, however, did not align well with her actual tea-making process, prompting her to ask whether she could construct her own graph that more accurately reflected her experience. To honor and harmonize with her way of thinking, I agreed.

Jocelyn's Engagement with the Tea-Making Task

To guide Jocelyn's thinking, I suggested using the y-axis of her graph to represent the sweetness of the tea as it was being prepared, while emphasizing that the final decision was hers. Jocelyn carefully considered the relevant quantities and how each one would influence the shape of the graph in its own way. For instance, she noted that the graph would look different depending on whether it represented the flavor of the tea or its sweetness, since the tea flavor was derived from the tea bag, whereas the sweetness came from the honey and oat milk. This distinction mattered to her because the addition of oat milk at the end of the process would have opposite effects depending on the quantity being measured: the graph would decrease if it represented tea flavor (as oat milk dilutes the tea) and increase if it represented sweetness (as oat milk complements the honey).

This reflection prompted Jocelyn to construct three graphs, each representing a different scenario (see Figure 2). First, she drew a graph representing the sweetness of the tea (purple graph). She then created a second sweetness graph that accounted for the effect of stirring during the steeping process (2–5 minutes) (black graph). She noted that sometimes she stirred the tea with a spoon while it steeped, which led to a sharper rise in sweetness. Finally, Jocelyn drew a third graph, this time representing the change in tea flavor (red graph). In this graph, she considered that roughly 80% of the tea bag's flavor would be absorbed into the water within the first minute of the steeping process, resulting in a sharp increase in tea flavor between minutes 2 and 3, followed by a much slower increase between minutes 3 and 5.

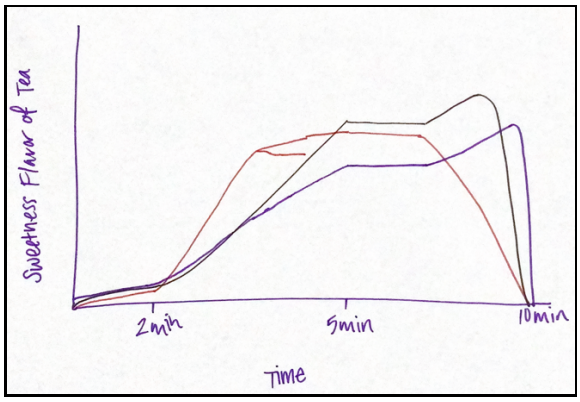

Figure 2: Graphs Associated with Sweetness and Flavor of Jocelyn's Tea

To help Jocelyn hone in on a single quantity, the teacher-researcher suggested that she draw a new graph measuring the blackness of the tea over time. This quantity was less ambiguous, as it

allowed her to focus specifically on how the tea's color changed, independent of its sweetness or flavor. Her graph had three key phases (see Figure 3): (1) the steeping phase (0–1 minute), where boiling water was added to the cup, and the tea bag began releasing its dark color into the water; (2) the resting phase (1–3 minutes), where the tea bag was removed, and the blackness remained stable; and (3) the pouring phase (after 3 minutes), where oat milk was added, lightening the tea's color until it became nearly white.

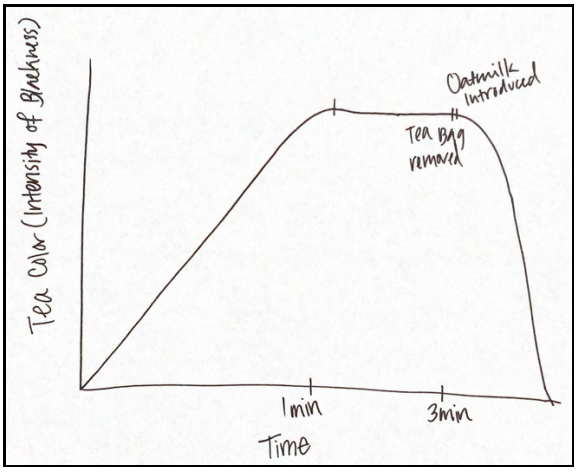

Figure 3: Jocelyn's Blackness of Tea Graph

Jocelyn explained that she connected the steeping and resting phases of her graph with a smooth curve to represent the final twenty percent of the tea absorption process. To better understand how she was reasoning about the variation in the tea's blackness during this interval, I asked her to describe how she conceptualized that final twenty percent of absorption.

Jocelyn: Umm, cause like you can see it's still absorbing, it's just slow. So like, instead of ... [3 second pause] I guess maybe there's, like ... [4 second pause] another way that I could have represented this is, at the three-minute mark, like all the time before then [slides marker along portion of graph to the left of the 3 minute mark], could have still had a rising, but just like an even more dramatic, like slower [uses marker to trace out the left side of what appeared to be a concave down parabola], like slow down, instead of just immediately going to having this be basically flat [points to horizontal flat portion of graph]. Umm, cause then, I feel like that could have more accurately represented the last like twenty percent, of it. Umm, but yeah, that's kind of, that's what I was thinking.

Jocelyn's explanation indicated that she understood the tea continued to absorb prior to the three-minute mark, but at a slower rate. This suggests that she recognized the blackness of the tea was not changing at a constant rate throughout the steeping phase. Jocelyn added that she could have made this even more apparent by extending the curve's leveling-off period to the three-minute mark, emphasizing an even "slower … slow down." Her choice of words, combined with her hand gesture tracing the left side of a concave-down parabola in the air, suggests that she was attending to the variation in the intensity of the tea's blackness over time. While her graph may not have been precise, it was clear that she understood the concept qualitatively.

Establishing a CMCR with Jocelyn

Although I cannot definitively conclude that learning occurred during this session (i.e., there is no clear evidence that her way of thinking shifted), I nonetheless argue that a CMCR was established with Jocelyn. First, Jocelyn engaged meaningfully with the "Tea-Making" task, which elicited her intensive reasoning, suggesting that I harmonized with her cognitive structures. Second, she maintained a positive disposition throughout—never disengaging, but remaining focused and intellectually stimulated. This indicates that I harmonized with her affective responses, as she exhibited a state of calm energy. Third, although learning was not evident, the task was appropriately challenging as it invited Jocelyn to reflect deeply on the quantities embedded in her tea-making process (e.g., sweetness, flavor, blackness). This reflection supported productive reasoning, as she independently constructed multiple graphs to represent variation in these quantities over time. Finally, because the graphs emerged from her own tea-making experience, the task was intimately connected to her funds of knowledge.

Discussion

In this theoretical paper, I propose a framework for CMCRs that integrates Hackenberg's (2005a) MCRs with two central tenets of culturally relevant pedagogy: academic success and cultural competence. This framework offers one avenue through which cognitive researchers conducting teaching experiments can more explicitly attend to sociopolitical factors in their work. Doing so positions them to challenge the norm within cognitive research to overlook race, culture, and students' identities beyond mathematics—specifically by constructing models that foreground the powerful sensemaking of students from historically marginalized communities.

For instance, in the example presented in this paper, the CMCR established with Jocelyn did not yield clear evidence of learning, yet it supported productive reasoning that highlighted two important strengths. First, she demonstrated flexibility in reasoning within a complex context grounded in her funds of knowledge. She attended to multiple relevant quantities in her tea-making process—such as sweetness, flavor, and blackness—and reflected on how each shaped the form of her graph. She also considered external factors, including stirring and absorption, ultimately constructing multiple representations to capture the complexity of the situation.

Second, she demonstrated an appreciation for the importance of clearly specifying the quantity being measured when reasoning about rate of change. For example, she recognized that sweetness and blackness are distinct quantities and that modeling each would produce different graphical representations, and thus, different interpretations of change. Her insistence on clarifying what was being measured reflects a commitment to deeply understanding quantitative situations involving rate of change. Given Jocelyn's identity as a Puerto Rican woman, these strengths contribute to an anti-deficit model of her reasoning that challenges deficit discourses positioning Latino students as inferior in mathematics.

For the sake of transparency, I note that although the CMCR established with Jocelyn illustrates the strengths of the framework, it represents only one episode within a thirteen-session, six-week teaching experiment. Given the cyclical and iterative nature of CMCRs, fully understanding their potential requires examining the experiment holistically. There were numerous moments in which I struggled to maintain my CMCR with Jocelyn and had to refine my models of her mathematical thinking and affective responses to reestablish our caring relation. Despite these challenges, I argue that attending explicitly to cultural relevance ultimately enhanced the cognitive rigor of the experiment by demonstrating how students' mathematical learning and diverse identities can be meaningfully intertwined to support productive reasoning. In this way, CMCRs offer a path toward reimagining cognitive research as

a space where rigorous mathematics and cultural relevance work together to support learning.

This qualitative study examined how preservice teachers (PSTs) with multiple marginalized identities experienced a sense of belonging within mathematics teacher education. The study included participants who were Black, on the autism spectrum, LGBTQ+, and from economically disadvantaged backgrounds. Two themes are reported from the analysis: Caring Relationships and Classroom Supports. Findings illuminate how intentional relational practices and structured supports contributed to participants' sense of belonging. Implications highlight the importance of relationship-centered pedagogies that recognize and support intersecting identities.

Keywords: Culture and Asset-Based Pedagogies; Equity, Inclusion, and Diversity; Identity and Agency; LGBTQIA+

Introduction

This study investigated preservice teachers (PSTs) with multiple marginalized identities and their sense of belonging in their mathematics teacher education programs. Strayhorn (2019) described "a search for community, humanity, acceptance, and even visibility [as] core elements of sense of belonging" (p. 60). Perhaps more importantly, a "true sense of belonging is not about 'fitting in' but rather about acceptance, authenticity, and finding community as one's true self, just as you are" (Strayhorn, 2019, p. 38). In this way, belonging is deeply entangled with identity.

Osterman (2000) explained that when students feel a sense of belonging, they are more engaged in campus and classroom activities, form strong relationships with peers and faculty, and have higher academic performance. Moreover, when students lack belonging, low persistence and retention rates result (Strayhorn, 2012). Extensive literature exists investigating belonging as an important factor in college success for traditionally underserved students. Less prevalent, however, is how the intersection of marginalized identities may collectively impact a sense of belonging. Allen et al. (2021) suggest that although previous research has reported the importance of student-teacher relationships to belonging, "less is known about how to improve those relationships, as are the most effective types of supports that teachers can offer" (p. 541).

To address these gaps in the literature, and as part of a larger study, we sought to determine factors specific to professors' practices that supported PSTs' belonging in our programs. We purposefully selected four students who had multiple marginalized identities and conducted interviews to understand their sense of belonging in our mathematics education programs. Included in our sample were individuals who were Black, on the autism spectrum, LGTBQ+, and from economically disadvantaged backgrounds.

Literature Review

Retaining PSTs who have marginalized identities in our mathematics teacher education programs through graduation and successfully entering the teaching field is of paramount importance. Indeed, one of the Association of Mathematics Teacher Educators' (AMTE) long-

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

term goals for 2024–2028 is to "support and provide guidance on the high-quality preparation, recruitment, retention, and diversification of mathematics teachers across the variety of educational spaces" (AMTE, 2024). Retaining diverse teachers is even more complicated when they have multiple marginalized identities. For example, Hong et al. (2024) explain:

> Very little research has been conducted to address MMU [multiply marginalised and underrepresented] teachers. These teachers need to negotiate their identity not only in one dimension of oppression, but across multiple dimensions and intersections among them simultaneously, which puts them in the most vulnerable positions. (p. 764)

As we prepare MMU teachers, they are particularly vulnerable to non-completion. However, having a diverse teacher workforce is an important factor in the success of K-12 learners. For example, the National Academies of Sciences, Engineering, and Medicine explain "there is growing and compelling evidence that teacher-student racial match has important effects on student outcomes" (NASEM, 2019, p. 87). Redding (2019) indicated that Black and Latino/a students were perceived by teachers of a different race/ethnicity as disruptive and argumentative more often than teachers of the same race. He also found that Black students were more susceptible to exclusionary discipline and less likely to be referred for gifted and talented programs when their teacher did not match their race/ethnicity. His review suggested that Black students had greater academic success when their teacher was Black.

Shelton (2019) emphasized the importance of LGBTQ+ students having ally teachers. She reported on the 2016 GLSEN study, which found that LGBTQ+ students felt three times safer and attended school more regularly when they had access to ally teachers than students who did not. Furthermore, she reported, "ally teachers help to shape more supportive school contexts, which help LGBTQ students to perform better in school, including higher GPAs, [and] greater senses of school community and belonging." (pp. 292–293). We recognize the complexity of teachers outwardly living their LGBTQ+ identities in their school workplaces (Brett, 2024, Hong et al., 2024). However, when they are able to authentically live their identities in their classrooms, it can be transformational for students, according to Brett (2024).

Gómez-Marí et al. (2021) reported in their systematic review on teachers' knowledge of autism spectrum disorder (ASD) that mainstream teachers who teach ASD students lack training, confidence, and knowledge of the disorder. There are four interventions recommended at the high school level for ASD students: (1) behavioral interventions, (2) modeling, (3) self-management, and (4) social skills (Austermann et al., 2025). For gifted and talented students who are also autistic (twice exceptional or 2eASD), there are additional interventions that can impact student success. For example, Reis et al. (2022) determined that:

> The use of advanced content, interest-based enrichment, and strength-based strategies enhanced the academic success of these young people … Participants also explained that when interests guided their academic work, they were more motivated and engaged. (p. 4436)

Preservice teachers studying mathematics education may not necessarily be classified as gifted, but they are likely mathematically talented. As mathematics teacher educators, we should be informed about the nature of autism and how it might function in our students, and understand and be able to use interventions that have the potential to improve their success and retention.

Students who come from economically disadvantaged backgrounds, often first-generation college students (FGCS), have special support needs in college as well. Watts et al. (2023) emphasized the importance of caring relationships with professors and information about and

access to campus resources and services. He also underscored the importance of mentors, advisors, peer relationships and "acknowledgment and reinforcement of academic successes" (p. 38) in FGCS student success. Means & Pyne (2017) found that faculty who had "willingness to provide access to content via multiple modalities, recognition that gaps in prior knowledge required support and were not indicators of cognitive capacity, and regular outreach to students through office hours as well as other kinds of contact" (p. 917) helped bridge the gap for FGCS.

Each of these marginalized identities requires support, and when combining them for students with multiple marginalized identities, those support needs only escalate. However, supporting MMU students in teacher education programs is highly consequential because of the impacts those PSTs will have on the belonging and academic success of K-12 learners.

Theoretical Framework

Intersectionality (Crenshaw, 1989) was the overarching theoretical framework for the study. Social categories, such as race, gender, sexual orientation, socioeconomic status, and ability, are not always disjoint; it is often the intersectionality of identities that makes an individual's experiences unique. These intersectionalities can help researchers understand differences in the experiences of students who have less privilege than others. Crenshaw (1989) alluded to intersectionality as a chain of oppressions that can affect students with multiple marginalized identities simultaneously. At these intersections, Black students often face deficit-oriented discourses that position them as disruptive or mathematically inferior. Women of color in STEM often face discrimination and microaggressions (Dortch & Patel, 2017; Johnson, 2012) and are dissuaded by professors to continue in the sciences. Graham-Smith and Lafayette (2004) showed the level of care received from peers and faculty "overcomes the sense of isolation and separateness that a student with disabilities feels and gives him/herself the permission to nevertheless belong and succeed in a frightening and challenging college environment" (p. 90).

Though we utilize Crenshaw's (1989) Intersectionality as a focal framework for unpacking institutional systems, we also recognize the necessity of supporting frameworks. Namely, we draw upon the convergence of Critical Mathematics Pedagogy and Humanizing Pedagogy (Salazar, 2013), unified by Ethics of Care (Noddings, 2013; Valenzuela, 1999). The notion of "aesthetic care" (i.e., superficial kindness) versus "authentic care" is an important distinction Valenzuela (1999) makes in disrupting deficit narratives. When considering the importance of identity to belonging, we drew upon Jones & McEwen's (2000) Model of Multiple Dimensions of Identity (MMDI). This framework, developed using a grounded theory methodology and a diverse group of undergraduate women participants, provides a model of different identity dimensions such as sexual orientation, race, culture, religion, gender, and class, and their relative distance from the core identity *at a particular moment in time*. Integrating these frameworks has implications for how PSTs with intersecting identities can be supported. Their retention demands institutional supports that recognize their uniqueness as they leverage lived experiences to help reshape narratives about who belongs in mathematics spaces.

Research Methodology

Participants

The participants in our study were enrolled at a large, public institution in the southeastern United States. We used purposeful sampling to select students who had multiple marginalized identities. Our four participants chose their own pseudonyms. Two participants were Black, lesbian women. One of them faced housing insecurity, while the other faced food insecurity. Another participant was a transgender man on the autism spectrum. The fourth participant was

an asexual woman who struggled with poverty and an abusive family background. She was also on the autism spectrum. See Table 1 for a description of each participant's background and characteristics.

Table 1: Demographics and Background Characteristics of Participants

Wonder Woman	Ashley	Batman	Felix
Black Lesbian Woman, married Grew up in loving, supportive two-parent household; seven siblings Experienced food insecurity throughout childhood and college	White Asexual Woman Late autism diagnosis Experienced poverty, housing insecurity, abusive/addictive parents. Had traumatic brain injury.	Black Lesbian Woman Extensive network of family and friends Experienced housing insecurity during her program. Did not finish program.	White, Transgender Man (assigned female at birth) Supportive family Has Autism Spectrum Disorder Grew up in Church of Jesus Christ of Latter-Day Saints

Data and Data Analysis

Each participant was interviewed twice. After the interviews, one of the authors wrote narratives summarizing the interviews. Participants read their narratives and agreed they were accurate representations of their experiences in their mathematics education programs.

We used reflexive thematic analysis (Terry & Hayfield, 2021) to analyze our data. We familiarized ourselves with the data, while attending closely to our participants' experiences within intersecting social identities and power structures. Initial coding was guided by the theoretical frameworks, as we attended to experiences where participants described mattering, care, and how their professors affirmed their identities. Codes were grouped to generate themes, which we developed, reviewed, and refined to ensure analytic coherence and theoretical alignment. For example, the theme Caring Relationships contained fourteen code groups that reflected teacher factors prioritizing students' humanity, emotional needs, and lived experiences. Each code group was comprised of multiple quotations representing recurring patterns.

Findings

Although our analysis revealed four themes, we are only focusing on two of them for this paper: (1) Caring Relationships and (2) Classroom Supports.

Caring Relationships

Our participants felt the greatest sense of belonging in classes in which their teachers cared deeply for them. They wanted their professors to get to know them on a personal level. Felix wanted his professors to understand autism—to know what it means when autistic people are overstimulated and what an autistic meltdown would look like. He wanted them to understand that he struggles with tone and people thinking he was mean or sarcastic when that was not his intention. He wanted them to understand that he might not always be up to participating in class. He said:

> I think it's a really good idea, just like some kind of system where [I could communicate that] I'm just having a rough day. I might not be 100% present in class today. I don't really feel mentally equipped to participate fully in discussions. I'm imagining some kind of little note they can fill out before class and get to the teacher discreetly.

As a transgender man, Felix also wanted professors to give him messages of acceptance. He suggested that even small gestures can help, such as a PRIDE flag in the classroom or asking students to share their pronouns. He said, "I think any kind of subtle support that you can show is 100% going to be noticed by the students that you teach." When teachers make him feel like they care about him, Felix feels much more comfortable in their classrooms. He said, "I think also something that makes me feel comfortable and accepted [is when] teachers communicate and just try to get to know their students more on a personal level—when they show that they care."

Batman wanted her teachers to check in with her to see if she was okay. She wanted them to notice when she was not participating in a group. She struggled with peer interaction due to prior negative experiences and status hierarchies within groups. When working in groups, she felt alienated, explaining:

> I've gotten frustrated one time. And I said something to my group member. [I asked] why are you not listening to me? Why are you always looking away from me when I speak?

She said she noticed that some of her peers did not interact well with "people that look like me" and "people that act like me." She replied, "Well, for the most part it's [because I'm] a person of color. Um, it may be because I'm gay as well." She further explained, "But I know as far as like being African American, yes. I've seen other African Americans get put in the same boat as me." Batman said she never felt put down or alienated by her professors but often felt that way with peers. She wanted her professors to notice this and to do something about it. When she found herself homeless during her program, she did not want to share it with her professors at first. But when she felt she could no longer handle the pressure, she finally shared her situation. She said:

> Everybody just started helping me like the Care Center helped me a lot. They gave me a place to stay. And meal passes and stuff like that. And you guys showed an outpour of love to me, since that. I won't have to drop out anymore, because I was gonna have to drop out.

As a first-generation student, Batman was not aware of resources that were available to help her. Once her professors knew her situation, they helped her find access to help. She was able to get back on her feet. Her professors assigned incomplete grades to her that semester, which she did not know was an option, so she was allowed to complete the work later. Ultimately, we lost Batman. She withdrew from the program. However, we recently received a text from her saying "I've been substituting at an elementary school since January and I'm eventually going to enroll in school. Thank you for everything, your efforts and help will not go in vain."

Ashley struggled with belonging as a first-generation student. She struggled particularly in her pure mathematics courses because she was a woman and an education major. She felt as if her professors and peers did not feel as if she truly cared about mathematics. She said:

> I felt like kind of this double whammy in my content classes. Oh, you're both math ed., and you're a woman. You know, well, you can take notes in our groups. So that was a little bit uncomfortable, especially since I didn't face any of that in my other master's program. Because, you know, nobody questions why women are reading poetry.

She recounted a time when a professor gave her an explicit message of belonging:

> I was still feeling like a phony, an imposter … And then [the professor said], oh, you're really leading that group and really helping that group's thinking … Oh, my gosh, I'm not faking. I do belong here!

Ashley had an accident in the penultimate semester of her program. She had a traumatic brain

injury (TBI). As a first-generation student like Batman, she did not know incomplete grades were a possibility. She thought she would have to leave the program. She reflected on the help she received from one of her professors during this time:

> Having a professor who cared about you, and took a personal interest in your story, came to the hospital to see you, and then shared that story with other people … [There are people] who are … connected in a way that you aren't, and then they can get someone to open up their home to me … Sometimes we're given options like you should try this, go to this website, or send this email. … I have problems with depression and mental illness. I'm already struggling with a TBI, I cannot climb a mountain of tasks to secure myself a place to stay. So knowing that one of my professors was actually making phone calls and sending emails … just knowing there was a person who cared if I finished and cared if I lived …

Ashley graduated with a perfect 4.0 GPA and was selected as the outstanding graduate in her program. During student teaching, her students' scores outperformed veteran teachers' students.

Wonder Woman felt, as a poor African-American woman, that "I don't belong here. I'm not supposed to be here, because I don't see a lot of people that I can relate to." She was often the only Black woman in her mathematics classes. She often tried to "stay under the radar," and did not talk in class unless she had to. However, some of her professors developed a caring relationship with her and pushed her to share her thoughts during discussions of power and privilege as part of her undergraduate urban education program. She said:

> And she did push me to try to voice my opinion. I did at times, but most of the time I tried to hide from her. And the reason is I was insecure about how people would judge me based off what I feel, my experiences, and my opinion. But that class … it changed my life.

Wonder Woman earned two additional degrees at our university. During her graduate programs, she began to feel a much stronger sense of belonging and did share her thoughts about power and privilege. Unfortunately, she was met with resistance from her professor and peers:

> In my [graduate programs], I've been more vocal about being an African American lesbian woman. I had a teacher who commented on my discussion post and tried to get me to talk about something different. Because the topic at hand related to me being a lesbian, and me teaching kids who are trying to figure out that space … I've had classmates online to comment in a professional way, where it's not obvious … I've had a few classmates kind of negate what I was saying about, you know, being a lesbian, being an African American woman in the classroom, teaching certain kids who are dealing with certain things.

Wonder Woman is married with a son now, and has a picture of her and her wife in their wedding dresses on her desk at school. She is able to live authentically in her work and has developed caring relationships with her own students.

Our MMU students need more from their professors than traditional students. Caring relationships that go beyond aesthetic care to authentic care make all the difference in their experiences and success.

Classroom Supports

In addition to developing caring relationships with students, professors can also use classroom strategies that support students' sense of belonging. We are limiting our discussion to a few strategies due to space issues. Wonder Woman explained:

> I wish professors knew that I wasn't the typical student. I needed more than what they were

> giving. … The amount of different supports I have to give my kids, I feel like professors should do that in college as well, because everybody … don't learn the same. Everybody don't have the same strengths … So they should approach their lectures, their notes, their activities, they should have multiple ways of giving that to students in college.

Our first-generation college students need more support than traditional students, and they do not enter college with a sense of belonging. We have to actively build that sense of belonging through our classroom practices. For example, collaborative groupwork and Complex Instruction are often positioned as pedagogical structures for deepening mathematical understanding and fostering belonging (Cohen & Lotan, 2014). Complex Instruction can help address the status issues that arise within groups. Assigning competence and addressing status issues would help Batman feel that the teacher recognized her low status and did something to raise it.

Gilken & Johnson (2019) found that:

> Belongingness is better fostered by instructional interventions … in which students contribute actively to the construction of knowledge, and in doing so, become engaged participants. In this study, it is this engagement in the content-based peer feedback intervention situated within a [community of practice] that supports feelings of belongingness. (p. 43)

In one of the researcher's courses, students' mathematical identity and sense of belonging were supported by intentionally promoting discourse and writing in mathematics. Throughout the course, students were encouraged to construct their own proofs, revise them through peer and instructor feedback, and engage in structured discussions about the logic and structure of mathematical arguments. These low-stakes, whole-class discussions created a supportive environment where students could share developing ideas, pose questions, and receive affirming responses from their peers. This process not only strengthened students' reasoning and communication skills but also positioned them as legitimate contributors to mathematical knowledge. When reflecting on what it meant to choose who she wanted to work with, Batman explained, "you feel respected, and you get to see your own work, and not just what somebody else put in …, it just matters." By centering student voices and encouraging reflection through writing and dialogue, the researcher helped foster a classroom culture where all students felt seen, valued, and capable of doing rigorous mathematical work.

This researcher also uses a culminating poster session as both an assessment tool and a means of cultivating students' identities as capable mathematical thinkers and supports their sense of belonging. Throughout the course, students engage deeply in mathematical writing and discourse, developing and revising proofs that reflect their growing understanding (Jansen, 2020). The poster session invites students to present two of their own proofs to peers and faculty in a public forum, like a poster session at an academic conference. This requires them to synthesize their work, reflect on their learning, and communicate their reasoning with clarity and precision. Batman indicated that it "matters" that the instructor created space for students to showcase their own work, explaining:

> So I honestly like the single work, when you just get to do your own project and present it, we had a project at the end of our class where we pick the topic. And I like when I get to showcase my own stuff, my own learning, and not be suppressed in a group.

Research (i.e., Koestler et al., 2024; Laursen et al., 2014) has shown that opportunities for students to talk and write about mathematics in collaborative, low-stakes environments foster a

stronger sense of belonging in the discipline. By giving students a platform to share their voice and expertise, the poster session helps create an inclusive classroom culture where each student is valued as a contributor to mathematical knowledge.

Discussion

Students with multiple marginalized identities can experience mathematics teacher education as a site of exclusion, marginalization, and conditional belonging. Jones & McEwen's (2000) MMDI posits that different dimensions of identity surface in different contexts. For example, when working with peers, it was Batman's racial identity that acted to suppress her belonging. But when she was in crisis, her poverty and first-generation status left her struggling with no knowledge of campus resources. In her mathematics classes, Ashley's gender and major affected her sense of belonging, but when she suffered a TBI, like Batman, she needed the support of her professors and community resources to recover. Ashley withheld her sexual orientation throughout her undergraduate program as she struggled most critically with race and poverty to belong in college. As her belonging increased after earning degrees, she began to explore the impact of her sexual orientation on her experiences as a student and teacher during her graduate programs. Those explorations were not well-received by a professor and peers. Felix needed explicit messages of belonging as he searched for acceptance to be able to live his authentic self as a transgender man, but often his autism acted more on his everyday interactions with peers and teachers. As MTEs, we must work to intentionally create inclusive environments that foster belonging and to allow students to live their authentic selves. The most important practices we can use to support students' belonging, especially for MMU students, are to show them authentic care and acceptance, hold them to high expectations of learning, and help connect them with support services. Creating low-stakes spaces where students can try out strategies, revise and refine them, and then publicly share them gives students confidence in their knowledge. Grading itself, Noddings (2013) argues, is a violation of the caring relationship because grading is not done for the good of the student; rather it is done to demonstrate the students' learning to others. One way to alleviate this tension in the caring relationship is to allow the student to revise work until it meets the teacher's standard. This practice shows that the teacher believes the student can do high-quality work and cares enough to work with them to attain an image of themselves that is better than their current work. In this way, students do not feel as if they are behind their peers, and they develop a deep sense of belonging. They need their teachers to encourage them and give them explicit messages of belonging. Avoiding deficit discourses, MTEs can use strength-based strategies that tie into students' interests (particularly for ASD students) and give them access to advanced content. Along with low-stakes environments, the classroom environment must be suitable for sensory sensitivities and provide ways for students to communicate their daily needs to teachers.

Limitations

The most significant limitation is that not all marginalized groups were included. There were no emerging multilingual students, students with learning or physical disabilities, nor representatives from many other marginalized groups. Findings cannot be generalized to other groups, and other themes would likely have emerged with different participants. Our findings do align with findings from previous literature, which adds to the credibility of our study.

The impact of identity on students' mathematics learning is well documented in mathematics education research; however, some identity factors remain understudied. We draw on notions of mathematics identity and belonging to study how pre-service teachers perceive four concealable stigmatized identities (gender, sexual orientation, socioeconomic status, and mental health) impacted their own mathematical learning experiences and might impact the experiences of their future students. Data were collected through a qualitative questionnaire at universities in Australia, Canada, and the United States. Of the eight major themes identified, we describe four such themes in this paper pertaining to the pre-service teachers' perceptions that CSIs can impact confidence, opportunity, help-seeking, and motivation.

Keywords: Equity, Inclusion, and Diversity; Gender; LGBTQIA+; Teacher Beliefs

Disparities in students' mathematics learning experiences on the basis of identity, such as race, are well documented (e.g., Hsieh et al., 2021; Leyva, 2022). However, the influence of concealable stigmatized identities remains understudied. The term *concealable stigmatized identities* (CSIs) refers to identities that individuals can conceal, that are associated with negative stereotypes and/or social prejudices (Quinn & Earnshaw, 2013). In an effort to expand research on this topic, we developed and conducted a qualitative questionnaire for pre-service teachers in which we investigated the perceived impact of gender, sexual orientation, socioeconomic status, and mental health on the participants' own mathematical learning experiences and the mathematical learning experiences of their future students. We selected the first two CSIs as they relate to the core mission of our working group and the second two CSIs because we felt that they do not commonly appear in mathematics education studies. Guided by this focus, we sought to answer the following:

1. How do pre-service teachers perceive that their gender, sexual orientation, socioeconomic status, and mental health have impacted their own mathematics learning?
2. How do pre-service teachers perceive that gender, sexual orientation, socioeconomic status, and mental health might impact the mathematics learning of their future students?

We ground our work in scholarship on mathematics identity and belonging (Nasir & Cobb, 2007; Walton & Cohen, 2007), as well as mental health and academic success (Eisenberg et al., 2009). Specifically, in this study, we conceptualize mathematics learning as being shaped by the interaction of structural, identity-based, and psychological factors. Students do not encounter mathematics in a vacuum; rather, their engagement and persistence are influenced by the resources available to them, their sense of belonging, and their psychological well-being. Structural conditions such as socioeconomic status shape access to instructional materials and

academic support, whereas identity processes influence whether students see themselves—and are recognized by others—as legitimate participants in mathematics (Martin, 2009; Nasir & Cobb, 2007). Psychological well-being mediates attention, motivation, persistence, and cognitive endurance in mathematics, a discipline characterized by cumulative content, high cognitive demand, and cultural narratives of difficulty (Eisenberg et al., 2009). Consequently, mathematics learning is positioned as a socially situated process in which engagement and persistence are shaped by access, belonging, identity, and mental health (Gresalfi & Cobb, 2006).

Methods

Data Collection

Data for this study were collected through an open-ended questionnaire administered at two universities in the United States, one in Canada, and one in Australia. Participants were recruited by instructors who were teaching pre-service teachers at the time of data collection (e.g., via announcements on course websites). In the questionnaire, pre-service teachers were invited to share their identities with respect to gender, sexual orientation, socioeconomic status, and mental health, as well as the impact of these CSIs on their mathematics learning and the mathematics learning of their future students. For instance, one of the prompts was "How do you think that your gender impacted your mathematics learning as a student?" The anonymous questionnaire primarily contained open-ended questions and took approximately 10–15 minutes to complete.

Data Analysis

We received 147 responses to the questionnaire. However, 35 were blank or partial responses, which we excluded due to incompleteness. Of the remaining 112 responses, 17 respondents indicated they were not planning on teaching mathematics at any level and were thus removed so that we could restrict our focus to pre-service mathematics teachers, resulting in 95 responses in the final data set. The responses were analyzed through analytic discussion and notetaking (Keane, 2022), which allowed us to identify recurring patterns across participant responses and create inductive themes across the data set (Gibbs, 2007). In this report, we frame a subset of these themes through the responses of four respondents chosen for their richly detailed answers that elucidated the themes identified. All names are pseudonyms.

Participants

Lincoln is pursuing certification in secondary school mathematics teaching in the United States. He identified as cisgender, asexual, and middle SES, and shared that he has anxiety and ADHD (attention-deficit/hyperactivity disorder). Ruby is pursuing certification in elementary and secondary school teaching in Australia. She identified as cisgender, straight/heterosexual, and middle SES, and shared that she has anxiety, OCD (obsessive compulsive disorder), and PTSD (post-traumatic stress disorder). Akask is pursing certification in secondary school mathematics teaching in Canada. He identified as two-spirit (FTM, man), asexual, gay/homosexual, aromantic, and low SES, and shared that he has depression, OCD, PTSD, and avoidant personality disorder. Sammy is pursuing certification in secondary school mathematics teaching in the United States. They identified as a demigirl, asexual, bisexual and/or pansexual, graysexual, and low SES, and shared that they have anxiety, OCD, ADHD, and autism.

Findings

We identified eight major themes through thematic analysis of the pre-service teachers' questionnaire responses (Table 1); however, due to space limitations, we restrict our findings here to the four themes italicized in the table, each of which relates to a different CSI.

Table 1: Eight Major Themes Identified in Survey Responses

Gendered Expectations Shape Confidence and Opportunity	*Mental Health Affects Motivation, Focus, and Depth of Learning*
Socioeconomic Status Determines Access and Time for Learning	*Sexual Orientation is Irrelevant to Mathematics Learning*
Low SES is Linked to Shame and Reduced Help-Seeking	Intersectional Experiences Compound Perceived Learning Challenges
Representation and Belonging Influence Engagement	Mathematics Amplifies Existing Stressors

Theme 1: Gendered Expectations Shape Confidence and Opportunity

Participants often framed mathematics as a masculine activity and discussed gendered expectations as a factor that influenced their mathematics learning. For example, Ruby highlighted that "the males in the classroom were always favoured in math and females were favoured in English." This led her to perceive that the men in her classes were receiving greater support and were viewed as more mathematically capable than the women. Sammy also addressed the exclusion of femininity in mathematics, stating that, "social conditioning encourages people assigned female at birth to not conform to the competitive, individualistic standards of math classrooms," suggesting that Sammy sees mathematics learning environments as rewarding stereotypically masculine forms of communication and performance.

When reflecting on how gender might impact their future students, Lincoln acknowledged that anyone who does not see their gender represented "may feel it's not possible for them" to study mathematics. He emphasized representation, rather than masculinity, as central to his understanding of the potential impact of gender on mathematics learning. In contrast, Akask referenced the masculinity of mathematics, also discussed by Ruby and Sammy, by arguing, "If patriarchal gender roles and stereotypes are a major aspect of a student's life, their confidence in their mathematical abilities would be affected by such gender roles."

Theme 2: Low SES is Linked to Shame and Reduced Help-Seeking

Participants frequently described socioeconomic status (SES) as a factor that impacts access to learning resources. Akask reflected on needing to borrow mathematical tools from his teachers and emphasized that his low SES made it "difficult to get access to a tutor or be able to spend time after school to receive help for math," a consideration echoed by Ruby. Sammy expanded this point to a systemic level, arguing that funding "is a huge barrier to education in general."

Participants also shared beliefs that lower SES is associated with lower self-confidence and a hesitancy to seek out support. Akask stated that "a low SES may lead a student to believe they're less capable of learning than their peers, … and intense shame when asking for help." Sammy also noted that scholarships "can help but also have a shaming aspect." Hence, to Akask and Sammy, SES can be a psychological constraint as well as a material constraint, negatively affecting a student's mathematical identity.

Theme 3: Mental Health Affects Motivation, Focus, and Depth of Learning

Participants described mental health challenges as a significant factor that shaped their mathematics education, affecting their motivation, focus, and depth of learning. Conditions such as ADHD, depression, and anxiety were often cited as interfering with engagement as well as the ability to study and seek help outside of class. For example, Lincoln stated that "the ADHD made it difficult to pay attention in many of my math classes," a sentiment also shared by Akask.

Mental health challenges were also linked to fragmented learning goals. Akask mentioned that his mental health and ADHD contributed to his lack of attendance; persistent absences can create gaps in understanding that widen over time. Akask also connected mental health to his help-seeking behavior: when asked how he perceived mental health as impacting his mathematical learning, he stated that "when it came to doing the work in math, I struggled to ask for help due to fears of being judged or humiliated for having the wrong answer." We see this as evidence that Akask's experiences with anxiety and ADHD may have affected his ability to seek help, therefore impacting his depth of learning.

When reflecting on how mental health might affect her future students, Ruby suggested that "if students aren't in the right headspace, it is difficult to make them learn," a sentiment consistent with Lincoln and Akask's lived experiences. Sammy also addressed the importance of their future students having access to accommodations for mental health struggles, arguing that "without adequate supports and communication, the toolbox available to help students work in the disability system can be a fast track to failure."

Theme 4: Sexual Orientation is Irrelevant to Mathematics Learning

Of the 95 participants, 94 did not feel that sexual orientation impacted their mathematics learning, a response that was consistent across all sexual orientations. For example, Akask (aromantic) stated that he did not see an impact since he's "had plenty of time to be comfortable in my orientation since coming out at 12 years old." Sammy and Lincoln (asexual spectrum) also did not feel that their sexual orientation impacted their learning.

When asked to reflect on how their future students' sexual orientation might impact their mathematics learning, participants were unsure if there would be an impact. A few shared that it may cause harassment, though Lincoln noted that the harassment would not be unique to the mathematics classroom. Similarly, Akask noted that "a student being bullied or pressured to hide their orientation may not be fully focused on learning." Thus, sexual orientation was perceived by these participants as a learning concern primarily in relation to social discrimination.

Discussion and Conclusion

Through this study, we found that pre-service teachers in the United States, Canada, and Australia demonstrated an awareness that mathematics learning is dependent on social and psychological factors, consistent access to resources, students' sense of belonging, and the ability to withstand the high cognitive demands of mathematics work both within and outside the classroom. These findings are consistent with research findings showing that confidence and participation in mathematics is influenced not only by measured ability but also by gendered expectations, representation, and classroom placement practices (Nasir & Cobb, 2007; Walton & Cohen, 2007). Together, these factors can signal which students are perceived as capable of succeeding in advanced mathematics.

As mathematics education researchers continue to discuss the impacts of student identity on mathematics learning, we call for increased consideration of CSIs and hope to incorporate intersectional analyses of these identity factors in our future work.

THEORIZING WHITE CHRISTIAN NATIONALISM IN MATHEMATICS EDUCATION

Kate R. Johnson
Brigham Young University
johnson@mathed.byu.edu

Some Christian mathematics educators express discourse that reflects interconnectedness between their conceptions of mathematics and divinity, including the idea that "mathematics is the language of God." For believers, God assumes a privileged status at the top of ideological hierarchies. Thus, seeing mathematics as interconnected with God imbues mathematics with a high status. Such hierarchical thinking is reflected in the discourses mobilized by adherents to White Christian nationalism to promote marginalizing agendas in social and educational contexts. In this theoretical paper, I begin exploring the nature of the discourses that some Christian mathematics teachers may hold and describe how they align with the harmful discourses in the White Christian nationalism movement.

Keywords: Equity, Inclusion, and Diversity; Identity and Agency; Social Justice

In spite of the so-called "separation of church and state" in the United States and other countries' public school systems, scholars have studied the religious identities of teachers and students in education (e.g., Hadley & Fassbender, 2020; Hartwick, 2015a, 2015b; Häusler et al., 2019; Journell, 2018; Subedi, 2006; Weyand & Juzwik, 2020) and in mathematics education specifically (e.g., Amir & Williams, 1999; Chan & Wong, 2014; Leu, 2005; Norton, 2002; Taylor, 2013). Research has shown that some religious teachers see teaching as a calling, a divinely inspired career pursuit (White, 2010), and they seek divine guidance to inform their teaching and their relationships with students (Hartwick, 2015b; Vaccino-Salvadore, 2021). Religious identities shape pedagogical practices (e.g., Hadley, 2021; Journell, 2011, 2018; Petrova, 2016; Shekitka, 2022). In other content areas, some Christian teachers identify tensions between their commitments to God and commitments to an inclusive education (e.g., Hadley, 2022; Hadley & Fassbender, 2020; Journell, 2011). As they navigate these tensions, they use marginalizing discourse about their students (e.g., Hadley, 2021; Hadley & Fassbender, 2020; Johnson et al., 2021) and limit students' opportunities to learn (Hadley, 2022; Olshefski, 2021).

A majority of teachers (over 85%) in the United States identify as Christian (Hartwick, 2015a), but those in public schools may not feel comfortable discussing how their religious beliefs are intersecting their work as teachers (Hadley & Fassbender, 2020; Weyand & Juzwik, 2020). Working at a private institution for over a decade has afforded me glimpses into how some Christian mathematics educators, mathematicians, and prospective and practicing mathematics teachers see their religious identities intersecting their work as they feel more free to express their beliefs in this context. They have asserted that "mathematics is the language of God" or "God used mathematics to create the universe." I do not think their beliefs are unique to their particular faith traditions as it is mirrored in the (scant) literature in this area (particularly, Chan & Wong, 2014; Leu, 2005; Norton, 2002); however, as these ideas are seldom discussed, it is hard to understand the breadth and depth of their impact on mathematics education. Nevertheless, if over 85% of mathematics teachers are Christian (matching Hartwick's (2015a study), then it is important to study what discourses they could be bringing to their learning and work as mathematics teachers.

Understanding these discourses may be particularly important in the context of the current sociopolitical movements happening in the United States (US)—namely, the White Christian nationalist agenda becoming increasingly visible in legislation, governmental priorities, and judicial decisions (Gorski & Perry, 2022; Whitehead & Perry, 2020; for examples, see also Burke & Hadley, 2025; Burke et al., 2023; *Carson v. Makin*, 2022; Cline & McGill, 2024; *Kennedy v. Bremerton School District*, 2022). White Christian nationalism (WCN) is a sociopolitical movement that draws on racialized, theological, and political arguments to assert that the US was founded to purposefully be a White and Christian nation (Gorski & Perry, 2022; Whitehead & Perry, 2020). To pursue what they see as divine intentions for the US, WCN supporters divide people into opposing groups: "those belonging to the divinely ordained nation-state imaginary (White Christian people like "us") and those who do not belong (people like "them")" (Burke et al., 2023, p. 287). Supporters believe in protecting their own group by any means necessary and maintaining hierarchical positioning in which White Christians benefit (Burke et al., 2023; Burke & Hadley, 2025; Gorski & Perry, 2022; Whitehead & Perry, 2020).

It is important to note that the term Christianity serves as a larger umbrella to many particular and diverse faith traditions (e.g., Catholics, Baptists, Methodists) and many Christians do *not* align themselves with the White Christian nationalist movement. However, I argue, alongside Gafney (2024) and others (e.g., Kaylor & Underwood, 2024) that it is necessary to examine the diverse discourses within Christianity:

> Liberation minded and justice-oriented Christians are a branch in a great tree of Christianity. Some of those other branches are rotten and producing strange fruit but they are part of the tree. Maintaining the health of the tree requires dealing with the rottenness within, cutting it off and rooting it out; not pretending it's not part of the tree. (Gafney, 2024)

Further, I argue that "justice-oriented Christians," like myself, need to reckon with the ways our theologies may still operate to marginalize others or have "created the fertile soil in which its most extreme versions now bloom" (Kaylor & Underwood, 2024, p. 22).

I see it as critical, then, to explore what Christian discourses could be silently becoming entangled with mathematics teaching and learning. In this theoretical paper, I explore possible implications of the conceptualization that mathematics is divinely created within mathematics education, particularly at the K-12 level. I began my theoretical exploration of this question by analyzing historical and philosophical accounts of mathematics emphasizing Christian perspectives (viz., Cohen, 2007; Howell & Bradley, 2001; Livio, 2009) as well as existing scholarship within mathematics education on Christian students and teachers (viz., Amir & Williams, 1999; Chan & Wong, 2014; Norton, 2002; Taylor, 2013). My theoretical analysis focused first on developing short but rich descriptions of possible discourses within the intersection of (some) Christian identities and mathematics education. Secondly, I tied these examples to discourses concomitant with White Christian nationalism to demonstrate how these discursive practices may be operating to privilege and oppress differing students. In the pursuit of equitable mathematics classrooms, I argue it is important to confront the ways Christian theologies may be and are entangled with mathematics education.

Divine Discourses in Mathematics Education

Describing mathematics as divinely inspired or used by God, minimally, reflects interconnectedness between the speakers' conceptions about the nature of mathematics and the nature of God. Elevating mathematics to a divine language has implications for the discourses a

mathematics teacher might draw on to describe their work and practices, which could have implications for how students are positioned. What are some of these discourses?

In the next two subsections, I present two vignettes that reflect themes in my theoretical analyses of philosophical and historical texts focusing on the intersections of mathematics (education) and the divine (viz., Cohen, 2007; Howell & Bradley, 2001; Livio, 2009) as well as the existing scholarship within mathematics education on Christian students and teachers (viz., Amir & Williams, 1999; Chan & Wong, 2014; Norton, 2002; Taylor, 2013). I read these texts looking for discourses that focused on the entanglements of Christianity and mathematics or mathematics education. For example, I located discourses describing the relationship of God to mathematics. Hobbes is quoted in Livio (2009) as saying, "geometry…is the only science that it hath pleased God hitherto to bestow on mankind" (p. 2). Further, I considered discursive patterns in the arguments. For example, in Livio (2009), the author elaborates examples of seemingly small mathematical ideas having applications much later in history as evidence of an underlying divine design. From this theoretical analysis and following a pattern of methodological practices inspired by poetic inquiry (Faulkner, 2020; Faulkner & Cloud, 2019; Hanauer, 2010; Hoult et al., 2020), I developed the two vignettes of the main ideas, presented in the next subsections. These vignettes use quotes and my own language to represent themes. I do not follow APA conventions within the vignettes to improve readability. Although some discourses are situated from a different historical time and context, I am arguing that the historical discourses resonate within some Christian mathematicians and mathematics educators currently because of their inclusion in the texts and articles I reviewed.

Vignette 1: On the Divine Nature of Mathematics and Doing Mathematics

"As the British physicist James Jeans (1877–1946) once put it: 'The universe appears to have been designed by a pure mathematician.' Mathematics appears to be almost too effective in describing and explaining not only the cosmos at large, but even some of the most chaotic of human enterprises" (Livio, p. 1). Thus, for Plato, "the mathematical character of the world is simply a consequence of the fact that 'God always geometrizes'" (Livio, p. 36). Further, Galileo and others believed that, "mathematics was simply the language of the universe. To understand the universe, … one must speak this language. God is indeed a mathematician" (Livio, p. 77). Consequently, "the ability to reason mathematics was thus a sublime present from God" (Cohen, p. 18). "Human beings exist in a cave of impaired perception, a profane realm of limited, imperfect things: matter, decay, ever-changing shapes. Above our muddled existence, however, is another, divine realm, a sphere of purity and eternal Truth. Mathematics plays a special role in this divided universe—it ascends from the world of impermanence to this higher, heavenly plane" (Cohen, p. 19). "It is not only the physical universe that is written in the language of mathematics; all of human knowledge follows the logic of mathematics" (Livio, p. 92). "In Descartes' words: 'Existence can no more be separated from the essence of God than the fact that its angles equal two right angles can be separated from the essence of a triangle'" (Livio, p. 116).

As a consequence, "at work the mathematician becomes a pure spirit, rising out of the confinement of his material body… He has no use for everyday faculties, like sight, but rather operates with a higher, far more powerful internal sense. This mathematical faculty is not a passive receptor of information, but is instead a penetrating instrument that attains the grandest of trust, all of which lie beyond the reach of our five bodily senses" (Cohen, p. 3). A mathematician uttered, "I prayed for an idea, God cared about that piece of work, and / An idea came into the world. The idea came into the world. / Seeing the immense amount of vagueness,

what can one person do? / One small step at a time, you shouldn't give up on the restoration of rigor. / And what surfaces at the end—that's God's" (Norton, p. 31). "Put differently, when a person finds a solution to a problem using proportional geometry, the insights and understanding gained are godlike" (Livio, p. 82). Doing mathematics means drawing closer to God—engaging in His practices and discourses. Doing mathematics is a calling. The evidence of His presence, with the mathematicians, echoes as mathematical understandings hold up across years and then decades and then centuries. These mathematical understandings find new purposes and uses in context never even dreamed of when first conceptualized. These examples become the evidence of God's hand. A mathematician beamed, "I'm amazed at how precisely Nature dances to the tune we scribbled so carelessly fifty-seven years ago, and at how experimenters and the theorists can measure and calculate her dance to a part in a trillion" (Livio, p. 223). "He [Descartes] declared that 'the mathematical truths which you call eternal have been laid down by God and depend on Him entirely no less than the rest of his creatures.' So the Cartesian God was more than a mathematician, in the sense of being the creator of both mathematics and a physical world that is entirely based on mathematics" (Livio, p. 116).

Vignette 2: On Divinity Within Mathematics Education

Teaching mathematics is a calling—an occupation one does in the service of God and because one believes that God would have them fulfill this role on Earth. A mathematics teacher stated, "God gave me the chance to take up this career. I do it seriously. … I have a mission. I believe in Jesus. I have a grateful heart. … I believe that I am just a humble woman. I cannot do anything by my own effort … My religion gives me so much grace. I know that I am just a humble woman. God put me in this good environment. I need to tend His [God's] kids, the little sheep. I need to work hard" (Chan & Wong, participant, p. 263). Another mathematics teacher stated, "I used to think that being a pastor was the only thing you could do [to serve God]…but I can see that I am not gifted to do that kind of work" (Norton, participant, p. 30). Mathematics teachers are "a channel used by God to bring mathematical knowledge to the world" (Norton, p. 30). "When studying mathematics, we know we are studying something God values" (Howell & Bradley, p. 248).

Teaching mathematics particularly can be a tool to draw students closer to God as they embody His practices and discourses. Learning mathematics is a means to get to know God on a personal level. Mathematics teachers should pattern their educative practices after God and not the ways of the world. "Christians should embrace the notion of centering the learning environment on students. This notion fits well within a view of our students as God's image-bearers" (Howell & Bradley, p. 355). Yet, the theory of constructivism that underlies many conceptions of mathematics teaching and learning is also flawed. "Sin has allowed this good structure [the theory of constructivism] to be distorted by those who would direct some aspect of creation toward purposes that do not seek to honor and glorify God" (Howell & Bradley, p. 355). "Constructivists assert that only active construction produces knowledge. It would seem unnecessarily limiting on God's creative power to conclude that knowledge can only be gained though [through] the process of construction" (Howell & Bradley, p. 357). "Christians must state clearly that ultimately we are not autonomous but instead depend wholly and completely on a creating, redeeming, and sustaining God. Any perceived autonomy on the part of the individual learner is instead God's precious gift of wisdom and understanding, not to be distorted into a situation where, as Saint Augustine extends Romans 1:25, humans 'worship and serve the creature rather than the Creator'" (Howell & Bradley, p. 358). "All knowledge comes from God, and a human's ability to comprehend knowledge is limited and incomplete" (Chan & Wong, p.

271). Christians should recognize God's hand in all things, including mathematics and Christian teachers should seek to share this knowledge with their students. Perhaps the NCTM standards ought to include a standard such as, "Mathematics as a means to recognize and describe the beauty, order, and regularity of God's creation" (Howell & Bradley, p. 359). Regardless of whether it is a standard, this idea must live within the hearts of Christian mathematics teachers.

White Christian Nationalism in Education

In previous scholarship, I, alongside co-authors, developed a conceptual framework for considering the intersection of education and WCN (Johnson et al., 2025). We sought to develop a theoretical and analytical framework that would identify some of the ways that WCN is seen in discourses about teaching and learning. We used Butler's (2016) concept of "frames" to identify two main ideologies associated with WCN. Butler conceptualized frames by discussing how photographers wield an instrument of war (the camera) because non-participants, such as citizens in their home country, only understand the war through what is present and not in images. As Butler wrote, "The frame does not simply exhibit reality, but actively participates in a strategy of containment, selectively producing and enforcing what will count as reality" (p. xiii). These frames position some people as privileged and others as precarious or ungrievable (Butler, 2016). Butler argued that the enemy within a war is considered ungrievable because, in their position as the enemy, they are already "lost, and cannot be destroyed" (p. xix). Those who inhabit this position are considered "precarious" before their deaths upon which they are rendered "ungrievable" (Butler, 2016). Ideological frames also operate to position some people as privileged, with their full humanity, and others as precarious or ungrievable (Butler, 2016).

Two foundational ideological frames of WCN are dominionism and colonialism (Johnson et al., 2025). Dominionism is the idea that Earth is God's kingdom and meant to accomplish His purposes (Johnson et al., 2025). Colonialism is the idea that Earth is where God's disciples live and they should grow in strength and numbers to accomplish His purposes (Johnson et al., 2025). Although colonization can take place through force (e.g., seizing land), our use of colonialism focuses on the work to spread the Christian (gospel) messages and, therefore, "the colonization of souls or spirits" (Johnson, 2025, p. 132). The frames of dominionism and colonialism are circulated through discursive practices—namely, divinely-ordered hierarchies, victimization, (anti)structuralism, and violence (Johnson et al., 2025). For example, discourses within WCN center "a God-ordained hierarchy, and there is no one higher in the social hierarchy than a straight White Christian man" (Johnson et al., 2025, p. 137). Using examples from practitioner texts written by Christian public school teachers (viz., Graham, 2011; Mason et al., 2015; Parker, 2012; Smith, 2022; Van Brummelen, 2009), my co-authors and I showed how these dominionist and colonialist discourses are seen in discussions of schooling (Johnson et al., 2025).

Dominionism

With respect to the discourses of victimization, these Christian teachers (who authored the texts we examined in Johnson et al. (2025)) described themselves as victims of governmental regulations restricting their rights to discuss their religious beliefs. A hierarchy is evident when Christian teachers talk about the different types of authority they have in the classroom (Johnson et al., 2025). As students are at the bottom of the hierarchy in the classroom, they are positioned as precarious or ungrievable. These Christian teachers certainly do not speak directly about engaging in physical violence in their classrooms but violence as dominionist discourses were evident when they described school as a battlefield or a "minefield" (Parker, 2012, p. 16). Christian teachers may see themselves as "warriors engaged in battle" (Johnson et al., 2025, p. 144) as they work within the dominionist frame. These metaphors positioned students as the

enemy and, thus, precarious or ungrievable—objects over which the teacher should exercise control and authority (Johnson et al., 2025).

Colonialism

Within education, the hierarchal discourses position teachers as having protective influence over students who are framed as precarious (Johnson et al., 2025). With respect to antistructuralist discourse, these Christian teachers described the public-school classroom as a mission field—one which had many opportunities for spreading the gospel message; however, they were frustrated by the governmental restrictions on religious expression in public schools (Johnson et al., 2025). Colonialist discourses of violence were evidenced when these Christian teachers wrote about why they needed to spread the gospel messages to their students (Johnson et al., 2025). They referred to students as "broken" and "sinful" and as needing rescue from the saving influences of Jesus Christ (Johnson et al., 2025). Because the teachers positioned themselves as the conduit to Jesus Christ, they enacted colonialist framings of students in which students' souls would be changed (Johnson et al., 2025). Students' own funds of knowledge or cultural practices were disrespected and they were rendered precarious, marginalized by the position of privilege the teachers saw for themselves (Johnson et al., 2025).

Frames and Discourses

In summary, two main ideologies associated with WCN are dominionism and colonialism. These frames shape how adherents to WCN, including teachers, see the world around themselves. In short, within the educational context:

> We can see that dominionism reflects an authoritarian relationship between the privileged and those who will be ungrievable. Within this frame, teachers believe their conceptions of how to behave or engage in concepts being taught are the correct or right ways. Alternatively, colonialism reflects a (mis)appropriation of the concept of love. In colonialism, the privileged seek to *love* the precarious into a different way of being–one that erases the humanity of the precarious. Within this frame, teachers see students as people who need saving from their own disbelief. (Johnson et al., 2025, p. 135–136)

These frames are upheld and circulated through particular discourses which continue to position some as privileged and others as precarious or ungrievable (Johnson et al., 2025).

White Christian Nationalism Discourses in Mathematics Education

Returning to the vignettes at the intersection of divinity and mathematics education, I now consider the ways the discourses align and not with WCN. Most prominently, the vignettes show hierarchical structure with God and mathematics at the top of the hierarchy. This hierarchy is expressed directly: "Human beings exist in a cave of impaired perception, a profane realm of limited, imperfect things: matter, decay, ever-changing shapes. Above our muddled existence, however, is another, divine realm, a sphere of purity and eternal Truth" (Cohen, 2007, p. 19). Human beings are positioned as inferior with the language "exist in a cave of impaired perception" while divinity is positioned as "above." The human being experience is described with words that connote poor conditions such as "imperfect," "decay," and "muddled." In contrast, divinity is described as "a sphere of purity." These contrasts show humans are (much) lower than divinity in a hierarchy. As Cohen (2007) continued, "Mathematics plays a special role in this divided universe—it ascends from the world of impermanence to this higher, heavenly plane" (p. 19). That is, mathematics is a part of the "higher, heavenly plane." It might be characterized as a bridge, but it also seems travel on the bridge only goes one way—from the human to the divine. These discourses reify hierarchical thinking commonly expressed in WCN.

With mathematics at the top of a hierarchy, there is a danger of dominionist and colonialist discourses of violence—ones in which mathematics teachers seek to diminish students' funds of knowledge to promote particular ways of knowing mathematics. They may dismiss students' interests in other subject areas (explicitly or implicitly) as they work to bring students into the divine light of doing mathematics, which reflects a colonialist perspective of students. Within this perspective, mathematics teachers can position themselves as saviors (cf. Hadley, 2021; Johnson et al., 2025) of the students, bringing them into a more enlightened way of being. However, this discourse renders the students precarious by oppressing their natural talents and interests. Further, mathematics teachers may believe that particular ways of doing mathematics are most aligned with God's uses. Thus, they may denigrate students' ways of knowing and doing mathematics in favor of these other particular ways. This approach to teaching mathematics can limit students' opportunities to develop a robust understanding of mathematics.

In Johnson et al. (2025), we saw evidence of the WCN discourse of antistructuralism when teachers were not trustful of the governmental oversight and restrictions of religious expression of teachers. We described a tension between antistructuralism, which resists restrictions, and hierarchies. "Although WCN does embrace rhetorical practices espousing antistructuralism in relation to governmental organization, at the same time, WCN does highly value structures that privilege White Christian men" (Johnson et al., 2025, p. 142). As a consequence, adherents to WCN have a tenuous relationship with ideas that seem to describe the world in ways that are antithetical to their interpretation of God's rules and principles. In their view, education is one of God's ideas, but humans may enact this idea in ways that are contrary to His principles (cf. Johnson et al., 2025). This perspective is reflected in the vignette primarily in the discussion of constructivism: "Sin has allowed this good structure [the theory of constructivism] to be distorted by those who would direct some aspect of creation toward purposes that do not seek to honor and glorify God" (Howell & Bradley, 2001, p. 355). This statement describes the perspective that "sin" can "distort" aspects of God's work on earth. Further, Howell and Bradley (2001) note that constructivism, as a theory, is "unnecessarily limiting on God's creative power" (p. 357). In other words, God's principles and practices are infallible, but humans may implement them inconsistent with God's work. What remains less clear is what kinds of theories of learning are consistent with God's work as many may be considered "unnecessarily limiting on God's creative power." This perspective can be used to reinforce particular ways of teaching mathematics that are more likely to be the ways the mathematics teachers construe as appropriate. These strategies might be more likely to position students as precarious in ways that are seen as desirable by adherents to WCN as they are promoting conformity to a particular way of teaching and learning mathematics that reifies the hierarchy.

As noted in the vignettes, both doing mathematics and teaching mathematics can been seen as callings from God—divinely appointed career pursuits (cf. Hartwick, 2015a; White, 2010). Mathematicians and/or mathematics teachers see themselves as drawing closer to God through their work. Thus, if creating (and learning) mathematics is an act of conformity to divinity, then teaching mathematics may be viewed as a surreptitious way of evangelizing. In Johnson et al. (2025), we showed that some Christian teachers view the public school system as a mission field as it is "filled with countless opportunities to live out our faith and draw others to Christ through our actions and reactions toward people and circumstances" (Parker, 2012, p. 16). Within the discourses about divinity in mathematics education, mathematics education itself might be a particularly powerful tool of evangelizing as students would find themselves solving problems through which "the insights and understanding gained are godlike" (Livio, 2009, p. 82).

Mathematics teachers may view themselves as "a channel used by God to bring mathematical knowledge to the world" (Norton, 2002, p. 30), which can reflect a colonialist view of the work of mathematics teaching. It is consistent with the antistructuralist and violent discourses of WCN that work to reify the hierarchy in which mathematics and divinity are intertwined at the top. This way of thinking becomes ordained through the further discourse that mathematics teaching is a calling. More directly, if mathematics teachers see themselves as divinely appointed to spread the message of mathematics in ways that draw people closer to God, then they are likely to position students as precarious and to believe that the students' position as precarious is the will of God. For adherents to WCN, this position is infallible—as it is God's, not theirs.

Discussion

Some mathematics educators are likely to approach mathematics teaching and learning with reverence for mathematics as having divine origin or having divine uses. In some Christian mathematics educators, either unwittingly or with awareness, this perspective may have consequences for marginalizing students. Both dominionist and colonialist discursive practices are present in the constellation of discourses within the entanglements of Christian conceptions of divinity within mathematics education. Thus, students may be marginalized through these discursive practices, which renders them precarious or ungrievable.

I do not assert that all Christians align themselves with the discourses in the vignettes above and have marginalizing perspectives of students. But also, as noted earlier, I argue that all Christians, myself included, must seek to understand the ways our theologies are entangled with and provide space for the increased marginalizations of others (students and other humans). As I worked to construct the vignettes and reviewed the texts and articles I examined here, I found both resonating and contradictory discourses among the data in the journal articles particularly (viz., Amir & Williams, 1999; Chan & Wong, 2014; Norton, 2002; Taylor, 2013), which reflected the authentic beliefs of Christians who were mathematics educators, mathematicians, or students learning mathematics. For example, Norton (2002) summarized a mathematician's Christian perspective, "the domain of mathematics does not stand out in importance from other secular studies, and the path toward Truth in these fields is not a direct one" (p. 31). Thus, I am confident there are discourses that mathematics, mathematics education, and the divine are not entangled in the ways represented in the vignettes presented above but I wonder how often they are the main focus of writing (although one example is Heie, 2002). At the same time, I do want to be clear that the vignettes represent themes seen across the texts analyzed: even in this example presented by Norton, the participant's perspective was contrasted against the prevailing, "Philip Melanchthon's philosophy [is] that 'the study of mathematics offers a vehicle by which the human mind may transcend its restrictions and reach God' (Methuen, 1998, p. 83) [which] makes mathematician and pastor one" (Norton, 2002, p. 31). Further, not all of the views expressed about the nature of mathematics and the nature of the divine are uniquely Christian.

In this theoretical discussion, I explored some of the possible intersections of WCN ideologies within the prevailing discourses on Christians' perspectives of God, the nature of mathematics, and teaching and learning mathematics. In short, there is danger of marginalizing and harmful discourses within the entanglements of the divine and mathematics education. It is unlikely that typical approaches to equitable mathematics teacher education are sufficient to disrupt these marginalizing perspectives as they are valued, by adherents, as divinely inspired. Thus, it is important that we, as mathematics educators, continue to deepen our understanding of how theology is wound within and around mathematics education so that we can work to develop equitable classroom spaces that value the humanity of all students.

A CRITICAL STUDY OF MARTIN'S *MATHEMATICS SUCCESS AND FAILURE AMONG AFRICAN AMERICAN YOUTH* AT 25 YEARS

UN ESTUDIO CRÍTICO DEL ÉXITO Y EL FRACASO EN MATEMÁTICAS DE MARTIN ENTRE LOS JÓVENES AFROAMERICANOS

Gregory V. Larnell
University of Illinois Chicago
glarnell@uic.edu

Written with sincere love from a colleague, collaborator, and friend, this report honors Danny Bernard Martin's scholarship by taking it seriously—not as past doctrine but as living theory. This analytical essay centers on Martin's (2000) Mathematics Success and Failure among African American Youth *and his subsequent scholarship with both appreciation and critique, recognizing that the highest form of respect for ideas is rigorous engagement with them. The essay argues that mathematics socialization—MSF's most important but least developed contribution—remains essential for understanding and addressing persistent racial inequity in mathematics education.*

Keywords: Affect, Emotion, Beliefs, and Attitudes; Equity, Inclusion, and Diversity; Identity and Agency

Introduction: The Necessity of Critique as Love

In memory of Dr. Khalel Hakim, a brother-scholar who left this world far too soon, and whose desire to publicly join a deep love for Black people with the possibilities of mathematics education continues to inspire.

In *Mathematics Success and Failure among African American Youth (MSF)*, Danny Bernard Martin (2000) shared that his work was both personal and professional—an unusual yet strategic admission that signaled essential features of his scholarly approach: embracing rigor without affecting objectivity, employing criticality without abandoning hope, and applying unflinching analysis animated by profound care. This was a pedagogical move. Martin was writing for and about Black children, Black families, and Black communities with the full weight of his scholarly training brought to bear on questions that mattered existentially, not merely academically.

A quarter-century later, as mathematics education faces renewed attacks on scholarship centering race and equity, as so-called "DEI" (i.e., initiatives that aim to address diversity, equity, and inclusion concerns) is transformed into a slur, and as hard-won spaces for critical examination relent to legislative pressures, the necessity of returning to Martin's foundational work has taken on fierce urgency. This essay undertakes that task—not as nostalgic commemoration but as critical engagement in the present with ideas that remain generative, frameworks that remain underutilized, and questions that remain unanswered.

Martin's style of analysis is both singular and unsparing—of deficit discourses that pathologize Black learners, of reform rhetoric that promises inclusion while maintaining exclusion, of research traditions that treat race as a demographic variable, and of systems that produce failure while blaming individuals and their communities. Yet his critique never becomes nihilistic. It emerges from and adheres to what we might call a profound love for Black people and an academic commitment to the transformative potential of mathematics education. This

distinction matters; there exists a meaningful difference between malicious critique and beneficent critique, which demands better because of a belief that better is possible.

The Emergence of *MSF*: Context and Intervention

To begin to understand what *MSF* accomplished, we must first discuss what it entered into. The 1990s marked a significant national ferment in mathematics education policy and curriculum development. The NCTM-led standards-based reform movement reached its peak with "Mathematics for All" as its rallying cry (see Martin, 2003). At the same time, the field underwent a "social turn," with increasing focus on sociocultural factors shaping mathematical learning. Yet something crucial remained absent. The field's attention to equity rarely translated into rigorous, theoretically grounded study of racialized mathematics learning experiences. Black learners, when they appeared in literature, were typically subsumed under broad categories like "minorities" or "underserved populations." This aggregation obscured the specificity of Black experience, erasing the particular forms of racism that Black students encountered (Martin, 2009).

The "Mathematics for All" rhetoric carried both promise and limitation. It was assumed largely that access was the primary issue; if gates could be opened wider, equity would be achieved. This framing took for granted what students were being given access to. It did not interrogate the nature or normative culture of school mathematics itself, the pedagogical approaches through which it was taught, or what mathematics education did to students' identities and sense of possibility.

MSF intervened by insisting that access, while necessary, was insufficient. Martin argued that we must examine not just whether students have access, but what their experience of mathematics education *is*—how it shapes their identities, constrains or enables their agency, and affects their sense of mathematical possibility. This shift from achievement to experience represented a fundamental reframing. Where reform discourse focused on what students produced, Martin focused on what mathematics education produced in students.

Core Conceptual Contributions from *MSF*

Among *MSF's* most significant contributions was developing a theoretically grounded framework for studying race, identity, and agency in mathematics education. Race was theorized not as a demographic variable but as lived, sociohistorical experience—a social construction with real material consequences, a system of power structuring opportunity and constraint (Martin, 2009). For Black learners specifically, race could not be understood apart from the particular history of anti-Blackness in American society and education (Martin, 2013).

Identity was conceptualized as negotiated, socially (co-)constructed, and mathematics-specific. Mathematics identity encompassed beliefs about oneself (Am I a "math person"?), beliefs about mathematics (What is it for?), beliefs about one's relationship to mathematics (Does it connect to my life?), and beliefs about mathematics in society (Who does it serve?). Crucially, Martin theorized mathematical identity as being shaped by racialized experiences—that is, formed in relation to deficit discourses, curricula that rarely reflected Black lives, and pedagogies that positioned some ways of thinking as legitimate while marginalizing others.

Agency was conceptualized neither as free will nor as complete determination but as strategic action within constraint. Martin rejected both hyper-individualistic notions treating agency as simply personal choice and deterministic frameworks positioning Black students as passive victims. For Black students in mathematics education—a space structured by white

supremacy—agency often took the form of resistance, of maintaining dignity in environments that denied humanity (Martin, 2013).

The power of Martin's framework relates to its ability to articulate relationships among these concepts. Race shapes the conditions under which mathematical identities are formed. Mathematical identities enable or constrain agency. Agency operates within racialized structures but is not determined by them. All three concepts must be understood together to comprehend mathematics learning experience.

Mathematics Socialization: The Most Important but Least Developed Contribution

If *MSF* is known for one contribution above all others, it is mathematics identity. Yet this very success obscures what may be *MSF's* most important contribution: the theory of mathematics socialization. While identity became widely popular, the broader theoretical framework within which Martin situated identity—the analysis of how mathematics socialization operates at multiple levels—received comparatively little sustained attention.

The Problem: Identity Without Socialization

As identity became a major research focus, it often became detached from the structural analysis that Martin's socialization framework provided. Studies examined individual students' mathematical identities without adequately theorizing the structural forces shaping identity formation. Identity became psychologized and individualized, treated as a property of persons rather than as representing the relationship between persons and systems.

This individualization had several consequences. First, it suggested the problem was students' identities rather than systems damaging those identities. Second, it depoliticized mathematics education—if identity formation was primarily psychological, then addressing identity did not require confronting power or challenging white supremacy. Third, it disconnected identity from collective and historical dimensions that Martin emphasized.

Martin himself has critiqued how identity has been taken up, noting the tendency to treat mathematical identity as a goal in itself without interrogating what mathematics is or whether strong identification with mathematics as currently practiced serves Black students' or communities' interests. These critiques point toward what has been lost when identity research is divorced from the broader framework of mathematics socialization.

Explicating the Theory of Mathematics Socialization

Martin conceptualized mathematics socialization as the complex of experiences, messages, and interactions that shape how individuals come to understand mathematics, their relationship to it, and themselves as mathematical beings. This was not simply learning mathematics but being socialized into particular relationships with mathematics and particular understandings of mathematical possibility.

Multi-level ecological perspective. Drawing from Bronfenbrenner, Martin conceptualized socialization as operating simultaneously at multiple, nested levels. At the individual level, students experience mathematics learning directly. At the interpersonal level, family members, teachers, and peers communicate messages. At the institutional level, schools make decisions about curriculum and tracking. At the community level, neighborhood resources and collective historical memory shape understanding. At the societal level, racism, economic structures, and accumulated historical legacies create the broad context.

Dialectical relationship between structure and agency. Mathematics socialization was conceptualized as dialectical—individuals were socialized within structures, but they also resisted, reinterpreted, and reshaped socialization messages. Structures socialized powerfully through tracking systems, deficit pedagogies, and institutional practices. Yet students were not

passive recipients—they interpreted socialization messages through lenses shaped by their own experiences, community knowledge, and critical consciousness.

Temporal dimension. Socialization was not a one-time event but an ongoing process unfolding across multiple timescales. At the immediate timescale, each encounter conveyed messages. At the biographical timescale, individuals' mathematical socialization extended across lifetimes. At the sociohistorical timescale, socialization operated through collective memory and accumulated legacies—expressed as a historical arc of educational exclusion extending from slavery and reconstruction to Jim Crow segregation and contemporary resource inequalities.

Content of socialization. Students were socialized into particular understandings of what mathematics is (fixed procedures or dynamic reasoning), of themselves in relation to mathematics (capable or incapable), of who belongs in mathematics (which students are marked as talented), and of what mathematics does in society (whose interests it serves). For Black students specifically, mathematics socialization occurred in relation to broader processes of racial socialization and in contexts structured by antiblackness.

Why This Framework Is Essential Now

Mathematics education has seen twenty-five years of equity-focused reforms since *MSF*—challenging tracking and "algebra for all" policies, introducing culturally relevant curricula, and producing waves of professional development in equity pedagogy. Yet racial inequities persist. This persistence cannot be explained by a lack of effort but points toward what the mathematics socialization framework makes visible: Inequity is reproduced through systemic socialization processes operating at multiple levels simultaneously. Equity reforms that do not address fundamental socialization processes cannot fundamentally alter outcomes.

Decontextualized identity work. Much contemporary identity research treats identity as an attribute individuals possess that can be developed through appropriate interventions, proceeding as if identity formation were primarily a psychological process. The mathematics socialization framework insists on reconnecting identity to structural forces. Identity is not simply something individuals have but something negotiated between individuals and systems, shaped by institutional structures, societal narratives, accumulated histories, and community resources.

Understanding resistance and resilience. Research often documents resilience—students who succeed despite hostile environments. Yet focusing on resilience alone risks individualizing structural phenomena, suggesting the solution is helping more students become resilient rather than transforming systems requiring resilience. The mathematics socialization framework provides tools for analyzing resistance structurally—asking how students resist harmful socialization, what resources enable resistance, how resistance operates at different levels.

Intergenerational patterns. Mathematics socialization is inherently intergenerational. Parents' experiences shape how they socialize their children mathematically. Teachers' experiences as students shape their beliefs about mathematics and students. Community histories shape collective understanding of what mathematics education means. Understanding these patterns is essential for addressing persistent inequity—cycles of negative mathematical socialization reproduce themselves across generations when not interrupted.

Mathematics Socialization and the Experience Frame

The theory of mathematics socialization is intimately connected to what Martin later articulated as the experience frame—that is, the focus on what mathematics education does to students rather than what students produce. The achievement frame focuses on outcomes—e.g., test scores, grades, and course completion. The experience frame focuses on what mathematics

education does to students—how it shapes identities, affects sense of possibility, constrains or enables agency.

Mathematics socialization is the mechanism through which experience operates. It is how mathematics education shapes students—through accumulated messages, structures navigated, practices encountered. The socialization framework explains how experience is produced, how it operates at multiple levels, how it connects individual lives to collective histories and structural forces.

This connection reveals that achievement and experience are related—achievement outcomes reflect experiential processes. Focusing exclusively on achievement obscures the experiential processes producing both success and failure and the meanings those outcomes hold. Transforming mathematics education requires attending to experience and socialization, not just outcomes.

Building from *MSF*: What Has Been Overlooked

While *MSF* has been widely influential, certain ideas have received less attention than they merit. Three overlooked threads deserve particular focus:

The Relationship Between Mathematics and Liberation

MSF explicitly connected to Bob Moses's framing of mathematics literacy as civil rights issue, examining how mathematics functioned in relation to Black freedom struggles. Yet this theme—mathematics education in service of liberation—remained somewhat underdeveloped. What would mathematical liberation actually look like? How might mathematics education serve liberatory projects rather than functioning primarily as gatekeeping? These questions become particularly urgent given Martin's later argument that equity discourse is insufficient. The goal cannot be including more Black students in mathematics as currently practiced; it must be transformation toward mathematics education that serves Black liberation.

Community Knowledge and Epistemology

MSF documented community forces shaping mathematics socialization and the intelligence with which Black families engaged with mathematics education. Yet less developed was interrogation of what mathematical knowledge existed in Black communities outside school mathematics and how this knowledge might transform what counts as mathematics. How might community mathematical knowledge transform what is taught in schools? What would curriculum look like if it began from community knowledge rather than treating community as source of "real-world applications"?

Collective Identity and Political Action

MSF focused primarily on individual identity and agency—how individual students formed mathematical identities and exercised agency within constraints. Less developed were questions of collective identity and collective action. How might Black students develop collective mathematical identity? How might mathematics education support collective action—organizing to demand better resources, challenging racist policies, using mathematical analysis to expose injustice? Transformation requires collective action; how might mathematics education cultivate not just individual competence but collective capacity for political action?

Martin's Scholarship After *MSF*: Evolution and Lessons

Martin's thinking has evolved significantly since *MSF*. Three developments are particularly crucial:

From Equity to Antiblackness

Martin's 2019 paper marked an explicit break from then-contemporary equity discourse,

arguing it is insufficient while allowing the field to claim commitment to justice—despite avoiding the harder work of naming and confronting antiblackness specifically. The shift to foregrounding antiblackness insists on specificity, challenges the field's comfort with equity language, and demands that mathematics education reckon with how antiblackness structures the field. This implies that twenty-five years of equity work has been insufficient, that the goal cannot be equity within systems structured by white supremacy.

Mathematics as White Institutional Space

Martin (2013) developed the concept of mathematics education as white institutional space—a domain organized by and for white participation, in which whiteness functions as unmarked norm and Blackness is marked as other. This means mathematics education assumes white cultural norms as universal standards, positions whiteness as natural belonging, and obscures its racialized nature. Understanding mathematics education as white institutional space suggests that transformation requires not just changing who participates but reconstructing mathematics education itself.

Equity as Delusion

Martin (2019) has increasingly critiqued how equity discourse functions, suggesting equity may be delusion—a promise that cannot be kept. Equity discourse focuses on distribution within systems structured by white supremacy, which may simply distribute oppression more equally rather than eliminating it. For Black students, equity may mean being included in spaces structured against them, achieving success by suppressing identity. This critique does not mean abandoning equity work but recognizing its limitations and understanding that equity cannot be endpoint—liberation is necessary.

The Fire This Time: The Current Political Moment

Twenty-five years after *MSF*, the political context has shifted dramatically. Coordinated political organizing aimed at rolling back social progress is targeting the institutional structures that support equity efforts. State legislatures have passed laws restricting teaching about race, universities have eliminated diversity offices, and scholars face coordinated harassment campaigns.

In this hostile context, *MSF* matters more than ever. It provides an intellectual foundation for resistance—demonstrating that scholarship centering race is rigorous intellectual work with strong theoretical foundations. It models engaged scholarship that is simultaneously rigorous and accountable to communities. It shows what's at stake—documenting how mathematics education functions as system of racial sorting, how it shapes Black students' identities and opportunities, how it constrains futures. When scholarship documenting these realities is silenced, systems continue operating without scrutiny, racism continues functioning without being named, students continue being harmed without accountability.

Conclusion: Bethinking Ourselves Anew

W.E.B. Du Bois called on Black people to "bethink ourselves anew"—to reflect critically on who we had been, to imagine who we might become, to envision futures not constrained by present oppressions. Twenty-five years after *MSF*, mathematics education needs its own renewed bethinking.

What Twenty-Five Years Teaches Us

Critique is generative. *MSF's* unflinching analysis did not destroy the field but made better research possible. Love manifests through demanding better, through refusing to accept systems that harm, through telling hard truths in service of justice.

Theory matters. Conceptual rigor is not academic luxury but essential tool for understanding and transformation. Without sophisticated theory, equity work devolves to good intentions without systemic understanding, to interventions addressing symptoms while leaving causes intact.

Black specificity is non-negotiable. Understanding mathematics education requires centering the particular history, present reality, and future possibilities of Black people. Generic frameworks abstracting from race or aggregating across different racialized groups are inadequate.

The work continues. Twenty-five years after *MSF*, mathematics education still functions as gatekeeping system, still sorts along racial lines, still requires transformation. This persistence clarifies what is needed: transformation requires deeper, more sustained, more comprehensive work addressing structures, culture, and ideology simultaneously.

The Charge: For the Love of Black People

MSF issued a charge that echoes across twenty-five years: that mathematics education should serve Black liberation, that we should pursue this work for the love of Black people, that we should refuse to accept anything less than transformation toward justice.

This charge means starting from the axiom of Black brilliance—assuming Black children's mathematical capacity, seeing potential rather than deficits, creating systems that nurture. It means pursuing transformation, not inclusion—reconstructing mathematics education rather than simply opening access to unchanged systems. It means maintaining community accountability—conducting research serving Black communities' needs, producing knowledge useful for transformation. It means sustaining collective struggle—recognizing that transformation requires organized action, political mobilization, coalition-building. It means maintaining courage across the long struggle—persisting when dangerous, protecting each other, refusing to abandon commitments.

To bethink ourselves anew is to engage in radical imagination—to envision mathematics education designed for Black flourishing, to conceive possibilities beyond present constraints. *MSF* began this bethinking, showing that different mathematics education was possible, that current patterns were not inevitable, that systems producing inequity could be understood and changed.

Twenty-five years later, we continue this bethinking. We do so with benefit of scholarship *MSF* inspired, with deeper understanding of challenges we face, with clearer sense of what transformation requires. We do so in more hostile political environment but also with stronger resolve. We do so in community, in struggle, in hope—holding fast to vision of mathematics education serving Black liberation, refusing to abandon that vision regardless of obstacles, working together toward futures where Black children's mathematical brilliance is assumed and nurtured, where mathematics contributes to collective flourishing, where education serves freedom.

This is the charge *MSF* issued. This is the work it began. This is the vision it holds before us.

For the love of Black people. For the transformation of mathematics education. For the possibility of liberation.

We continue.

Racialized and intersectional forces of oppression (e.g., stereotypes of ability) produce Latin undergraduates' discomfort with asking for help from instructors in gateway mathematics courses. Instruction plays a key role in reinforcing and disrupting such inequities of support. However, research about instructor-initiated support that expands Latin* mathematics students' access to help is limited. The present study adds such knowledge by examining student experiences of check-in practices in gateway mathematics instruction at a Hispanic-Serving Institution (HSI). We found that cultural influences, including the value of orgullo (protecting one's pride), added to Latin* students' help-seeking tensions due to shame associated with their bids for support. Mathematics instructors' check-ins were experienced as racially-conscious care that fostered equitable support aligned with campuswide efforts for serving Latin* students.*

Keywords: Culture and Asset-Based Pedagogies; Equity, Inclusion, and Diversity; Instructional Activities and Practices; Undergraduate Education

Background

Latin* undergraduates experience racial and intersectional oppression in mathematics courses that are gateways for graduation and STEM degrees, such as calculus, college algebra, and introduction to proof (Battey et al., 2022; Bhattacharya et al., 2020; Brown, 2018; Leyva, 2016, 2018, 2024; Rios, 2024). Structural inequities and ideological forces tied to racism and interlocking power systems (e.g., patriarchy, linguicism)—e.g., stereotypes of mathematical ability, isolation due to underrepresented identities, dominance of the English language in U.S. education—shape Latin* students' wariness of asking questions to instructors (Convertino et al., 2023; Leyva & Joseph, 2023; MacArthur & Dobie, 2023; Oppland-Cordell, 2014). Such constraints on help-seeking produce a racialized distribution of support. Considering how gateway mathematics success impacts long-term academic outcomes (e.g., STEM major persistence, mathematics identities), equitable access to instructor support is consequential.

Research on Latin* undergraduates' academic help-seeking suggests that cultural norms figure into tensions about asking for support in gateway mathematics. Cultural values of collectivism and interdependence give rise to concerns that others' negative judgment may jeopardize relationships. Such cultural influences like *orgullo* (protecting one's pride) and the *el qué dirán* (concerns about others' opinions) bring Latin* undergraduates, especially first-generation college attendees, to work through struggles on their own (Cabrera et al., 2016; Chang et al., 2020; Payne et al., 2023). Additional cultural influences are cisheteropatriarchal gender ideologies of machismo and marianismo, which valorize men's assertiveness and women's submissiveness (Estrada & Jimenez, 2018; Liang et al., 2017). Seeking support, as a result, conflicts with gendered expectations that Latin* men avoid displaying vulnerability and Latin* women remain quiet. Thus, Latin* students' cultural values as well as their realities of racial and intersectional oppression may present barriers for seeking help in mathematics.

Instruction can exacerbate or alleviate Latin* students' racially- and culturally-mediated concerns about asking for help in and beyond gateway mathematics. Dismissing bids for support

as well as showing limited consciousness for Latin* students' racialized realities and cultural backgrounds fuel help-seeking tensions (Kennedy & Hernandez, 2025; Leyva, Amman et al., 2022). Such instruction falls short in cultivating a safe, culturally-responsive learning context that expands access to support. However, instruction that honors Latin* students' contributions and cultural norms promotes a sense of belonging that mitigates risks in exhibiting struggle and asking questions (Convertino et al., 2023; Oppland-Cordell, 2014; Payne et al., 2023). Our prior work has shown that affirming Latin* cultural values of collectivism (e.g., building peer connections in groupwork), resisting stereotypes of ability, and framing the Spanish language as a resource builds a community for equitable classroom participation in mathematics (e.g., Leyva et al., 2025). Research on such instructional features for Latin* student support is needed.

Considering traditional norms in undergraduate classrooms that students initiate the process of receiving help, support for Latin* students in gateway mathematics has largely been explored in relation to help-seeking. Tensions with seeking support among Latin* students point to the value of research that examines instructor-initiated help as a disruption of such norms for equitable access to content. Such inquiry is crucial in gateway mathematics where exclusionary logics of the discipline, including innateness of ability and sorting out students not "cut out" for STEM, frame instruction in ways that leave help-seeking vulnerabilities unchallenged (Ellis et al., 2014; Leyva & Alley, 2021; Leyva, McNeill et al., 2021; Leyva, Quea et al., 2021; Perez et al., 2024). To address this need, our study explores how instructors' outreach to students, or "check-ins," impacted equitable support opportunities. Check-ins ensure that Latin* students receive academic and socioemotional support to foster their success in gateway mathematics courses. Examples of check-in practices explored through the present analysis include sending an e-mail message, touching base immediately after class, and scheduling office hour appointments. We address the following research question: *How does the absence and presence of check-ins influence Latin* students' experiences of equitable support in gateway mathematics instruction?*

Conceptual Model: Instructional Servingness in Undergraduate Mathematics

Servingness refers to culturally-responsive practices that enhance connections between Latin* student enrollment and equitable educational opportunities at Hispanic-Serving Institutions (HSIs; Garcia et al., 2019). U.S. colleges and universities with at least 25% Latin* enrollment receive a federal HSI designation and funding to support students' academic success. HSIs vary in the extent to which their campus structures and institutional practices advance servingness (Garcia, 2019; Núñez et al., 2015). Despite such variation, HSIs have a shared reality that Latin* undergraduates more frequently experience servingness outside of STEM departmental contexts like gateway mathematics courses (Herrera et al., 2022; Leyva, 2022; Leyva, Mitchell et al., 2022; Leyva et al., 2025; Shi et al., 2025). Limited research, however, has explored relationships between STEM instruction and campuswide servingness (Ro et al., 2024). Such inquiry is needed to strengthen continuity of servingness in and outside of STEM spaces. Our study fills this gap by examining opportunities to foster equitable support resonant with campuswide servingness through check-ins in gateway mathematics instruction.

Building on the general framework of servingness (Garcia et al., 2019), our team developed a model of *instructional servingness in mathematics* (Leyva et al., 2025). Figure 1 is a visual adaptation of our model. It accounts for three interrelated levels of influence on instructional servingness—society at large, HSI campuses, and the mathematics discipline. At the societal level (Figure 1a), the model considers Latin* culture and white cisheteropatriarchy (i.e., a system of oppression at the juncture of white supremacy, racism, cisheteronormativity, and patriarchy) that shape social realities in and out of mathematics. These influences encompass ideological

forces (e.g., stereotypes of ability, gendered cultural norms) and structural inequities (e.g., access to high-quality P-12 education) that give rise to Latin* undergraduates' help-seeking tensions.

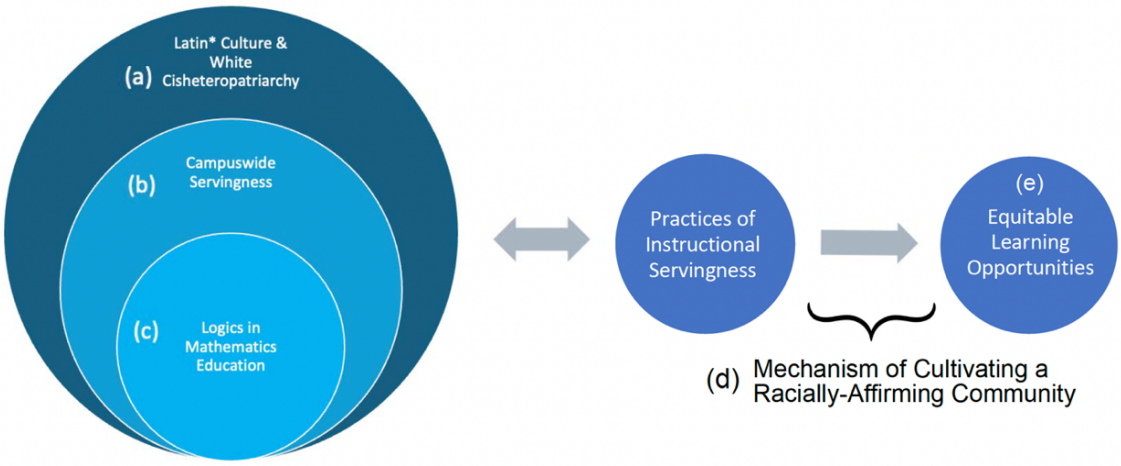

Figure 1: Model of Instructional Servingness in Mathematics (Leyva et al., 2025)

At the campus level (Figure 1b), the conceptual model attends to HSI structures that foster servingness by disrupting oppressive societal influences for equitable educational opportunities. Sources of campuswide servingness outside of mathematics classrooms include DEI offices and initiatives, student support services, and organizations for Latin* racial affinity in and out of STEM. Since these HSI campus structures extend race-conscious and culturally-responsive support, they remove pressures and stigma related to seeking help among Latin* students.

The model also accounts for influences of the mathematics discipline (Figure 1c). Namely, it considers dominant logics—e.g., individualism, innateness of ability, social neutrality (Battey & Marshall, 2023; Leyva, McNeill et al., 2021)—shaping instruction that contributes to Latin* students' vulnerability with exhibiting struggle. Disruption of these logics, in tandem with resisting white cisheteropatriarchy and embracing Latin* cultural values, builds a collaborative and identity-affirming environment in gateway mathematics classrooms. The model describes this as a mechanism of instructional servingness for *cultivating a racially-affirming community* (Figure 1d) to promote equitable learning opportunities, including instructor support (Figure 1e). By alleviating help-seeking tensions and facilitating access to content, these practices ensure continuity of campuswide servingness in mathematics. The model guided our inquiry of check-ins as practices of instructional servingness for Latin* students' equitable support opportunities.

Methods

Study Context & Data Collection

Our study comes from a larger project about instructors' and Latin* undergraduates' views of instructional servingness in gateway mathematics. The HSI site, Sonoma State University (SSU), is a medium-sized, public university in the western U.S. At the start of data collection, SSU undergraduates were approximately 45% white, 40% Latin*, and 15% some other race. Gateway mathematics instructors were predominantly white and commonly used active learning strategies (e.g., groupwork, whole-class discussions). The present analysis focuses on Latin* students'

views on servingness. We recruited 38 students from gateway mathematics courses, including multiple student voices in specific course sections and across ethnoracial/gender identities.

The research team recruited participants and collected data over two years. Findings reported later feature Year 1 participants, so we only discuss Year 1 data collection below. Year 2 data collection is presented elsewhere (e.g., Leyva et al., 2024). A total of 24 students in Year 1 (12 in fall and 12 in spring) kept a journal of instructional experiences—a log of written descriptions and reflections about events that expanded or limited support. We collected 114 journal entries.

Near the end of each semester, Year 1 participants completed a 90-minute, semi-structured, and virtual individual interview that was audiotaped and transcribed. The first half of interviews explored participants' identities and backgrounds, in addition to their views on being served as Latin* students in mathematics and across the SSU campus. In the second half, we presented two written prompts of instructional events, which each addressed a theme of instructional servingness across all instructor and student participants' journaling. Our team developed the prompts as syntheses of individual journal entries. The first prompt about classroom participation was written from a student perspective, and we report on an analysis largely focused on responses to this prompt elsewhere (Leyva et al., 2025). The second prompt about support (quoted below) was written from an instructor perspective and featured check-ins with a student who seemed to be struggling. Responses to this prompt were central in our present analysis.

> A student did not submit multiple homework assignments and missed a few weeks of class. I sent an e-mail message to check in with them and encouraged them to visit my office hours if they needed any support. The student was unresponsive. I approached the student during a class meeting and asked if they could stay after class to check in with me. The student and I worked together in developing a plan to help them catch up with the course material.

For each prompt, participants were asked about: (i) similarities to and differences from their experiences, (ii) oppressive and supportive aspects for Latin* students, (iii) connections to campuswide servingness at SSU, and (iv) suggestions to enhance instructional servingness.

Data Analysis & Positionality

The research team used a grounded theory approach for data analysis (Corbin & Strauss, 2014). First, two team members independently coded each student participant's data set. With the model of instructional servingness as a guiding lens, we flagged content with open codes that addressed *campuswide servingness* (Figure 1b) and *logics in mathematics education* (Figure 1c). Another set of open codes flagged *instructional practices* that Latin* students deemed oppressive or supportive, including absence and presence of check-ins (the central unit of our analysis).

Axial codes identified relationships between open codes to convey how mathematics instruction constrained or promoted continuity of campuswide servingness, which translated into *(in)equitable learning opportunities* like instructor support (Figure 1e). We used selective codes to document societal and cultural forces that texture open-axial coding relationships. These codes flagged influences of *Latin* culture* and *white cisheteropatriarchy* (Figure 1a) to reveal how instruction restricted or facilitated creation of a racially-affirming community—the mechanism of instructional servingness for equitable and culturally-responsive learning (Figure 1d).

Paired coders for each participant's data set exchanged their independent analyses to identify themes that provided theoretical explanations for how instructional servingness was limited and promoted (Corbin & Strauss, 2014). In team meetings, we shared participant-specific themes for a cross-case analysis of Latin* students' experiences. Three strategies sharpened validity and trustworthiness of our analysis: (i) prolonged engagement through multi-semester data collection (ii) triangulating and layering data sources, and (iii) ongoing debriefs and exchanges of analytical

memos. Three team members (this research report's authors) led the present line of inquiry based on the coded data and cross-cutting themes about instructor support for equitable learning. More specifically, we addressed our research question exploring the role of check-in practices in Latin* students' perceived opportunities for support likened to campuswide servingness at SSU.

For this report, we present findings from our analysis of data for 21 out of the 38 participants. We focused on these participants because they were enrolled in courses with instructors who taught most of our sample. This sampling also ensured representation across all course types in recruitment. Most focal participants, much like the broader SSU undergraduate population, are first-generation college students, come from low-income backgrounds, have Mexican heritage, and/or identify as cisgender women. Our analytical sample, thus, spoke to common Latin* student realities at SSU. At the same time, the sample had representation for other ethnoracial identities (e.g., Salvadoran) as well as cisgender men and nonbinary students to capture variation in Latin* student experiences. Ten of the 21 participants were interested in STEM majors.

We pursued the study with consciousness for our individual and collective positionality. Diversity across team members' identities (e.g., race, gender), professional roles (e.g., faculty, undergraduates), and institutional affiliations in and out of SSU provided multiple perspectives for data collection and analysis. Most of us identify as Latin* and/or first-generation college students, and SSU researchers (both undergraduate and faculty) make up nearly half of the team. We leveraged these insider perspectives on participant experiences by having at least one Latin* researcher present for each interview and paired coding assignment. An SSU researcher was included in each coding pair analyzing de-identified versions of study data. Our collaboration, thus, minimized risks of distorting Latin* participants' experiences during analyses due to team members' social proximity and distance. As a team, we adopted an asset-based orientation that positioned Latin* students' realities as knowledge for enhancing instructional servingness.

Findings

Our analysis uncovered two types of instructional realities. Two-thirds of the sample (n=14) reported supportive experiences with varied use of check-ins. The remaining seven participants experienced limited support with check-ins being largely absent. Below, we present a pair of illustrative cases for each type of instructional reality. The case pairs, respectively, depict how absence and presence of check-ins impacted Latin* students' opportunities for support with racially-conscious care. We conclude with a cross-case analysis using the model of instructional servingness (Figure 1), which shows how check-ins cultivated a racially-affirming community as a mechanism of instructional servingness for equitable support in gateway mathematics.

Absence of Check-Ins Limiting Equitable Support

This section highlights cases from Joana (Mexican woman, she/her, non-STEM major) and Monica (Latina nonbinary person, they/them, STEM major)[1] who reported limited support in instruction with an absence of check-ins. Joana saw her instructor as unaware that many Latin* students like her navigate conflicts between coursework and personal responsibilities of family support (e.g., part-time jobs, sibling care). She saw the dominant logic of STEM being "neutral" shaping her experience of limited racial consciousness in mathematics instruction, thus making her feel unseen as a Latina, "The professor being like, 'I recognize that this student is a Latina. Maybe she's going through something.' No, not at all… I'm just treated like any other student… It is a STEM class… We don't talk about that [identities]." She reasoned that check-ins would

[1] Course details, types of STEM majors, underrepresented ethnoracial identities among Latin* students, and mathematics instructors' racial and gender identities are not specified to avoid participant identifiability.

exhibit consciousness for her circumstances tied to the Latin* cultural value of *familismo* (family loyalty) by offering support to manage conflicts. Unable to attend tutoring due to personal commitments, Joana felt on her own to overcome struggles in mathematics without check-ins. Shame about help-seeking from the Latin* cultural value of orgullo (protecting one's pride), in tandem with a lack of check-ins, contributed to Joana's pressures of self-reliance in mathematics.

> There are heaps and heaps of Latino students that struggle with this [mathematics]… We don't get tutoring… because we have busy lives at home… [and] have to get jobs… We are shameful when asking for help because… [it] can sometimes be seen as weak for us, at least in the Latino mindset… You think, "I don't want to be a burden. I should be able to do this."

Joana's experience suggests how check-ins, which were perceived as entry points for providing racially-conscious support, can alleviate Latin* students' help-seeking tensions. She saw the destigmatization of seeking support as a need in gateway mathematics instruction, "If it was made more known that there's nothing wrong in asking for help and it's not a shameful thing… more Latino students would ask for help." Check-ins, thus, were viewed as building a supportive learning environment for mathematical success that was responsive to Latin* cultural values.

Monica also felt help-seeking tensions in their classroom with an instructor who did not use check-ins and was dismissive toward students' questions. As someone who "felt really behind" in mathematics after high school teachers did not meet their learning needs, Monica was wary that seeking instructor support could result in negative judgment for lacking foundational knowledge. Stereotypes of mathematical ability figured into these concerns with asking for help.

> He [mathematics instructor] was talking down to me a bit like, "Why don't you get this already?"… [His] condescending tone... [was] like, "You're not worth my time."… It [race] definitely could have contributed because especially just like my last name… it's really easy for people to… know I'm Latina… And [Monica] is also a very common female name.

Monica grappled with uncertainty about racialized and gendered undertones in their instructor's response during office hours, which made them avoid future help-seeking in mathematics. This instructional behavior reflects workings of a dominant logic that quickly understanding and completing work is an indicator of innate mathematical ability, in addition to a seeming lack of consciousness for Latin* students' racial inequities (e.g., limited access to high-quality education before college). These influences shaped Monica's vulnerability with seeking help in gateway mathematics, where knowledge gaps can be interpreted as deficits in students' potential for majoring in STEM (Leyva, Quea et al., 2021). Such vulnerability, as depicted in Monica's case, can be racialized and gendered for Latin* STEM majors navigating stereotypes of ability. Monica journaled how a lack of check-ins produces inequities of support that negatively impact Latin* students' STEM persistence, "We [Latin* students] already are underrepresented… and having teachers who aren't willing to help or are often unavailable causes for students to lose their interest in STEM… When they don't offer help [or] reach out… the student[s] must fend for themselves." Thus, Monica saw check-ins as defusing help-seeking tensions and promoting equitable support for mathematical struggles to nurture their success as a Latina STEM major.

Presence of Check-Ins Fostering Equitable Support

This section reports insights from two cases of supportive instructional experiences with the presence of check-ins. These cases came from Frank (Mexican man, he/him, STEM major) and Ofelia (Latina woman, she/her, non-STEM major). Frank's instructor used office hour meetings and e-mail to check in with students who seemed to be struggling. These check-ins, which Frank saw as "the professor really car[ing] about his students," shaped positive instructor-student

relationships. Frank perceived check-ins with Latin* students reflecting consciousness for his and his Latin* peers' responsibilities of family support that conflicted with time-intensive work in mathematics, "We [Latin* students] have outside problems like work… [and] helping the family… [Mathematics] requires a lot of time to submit assignments, to review problems, and to study… They [mathematics instructors] would see us like, we're going through a lot of stuff." Check-ins, therefore, were experienced as racially-conscious care for Latin* students' success.

Instructor care through check-ins motivated Frank to frequently ask for help after class. When describing servingness across the SSU campus, Frank raised his instructor's advice to seek campuswide tutoring and attend office hours, which he often did, "Encourag[ing] a lot of their students to go to…tutorings and their own office hours… If we have any more questions… we go to more office hours." Frank's instructor ensured Latin* students like him received help in and out of the course, thus cultivating a network of support that extended beyond the classroom. With Frank describing mathematics as one of the "very challenging" requirements for his STEM major, the instructor's supportive practices arguably were positive influences on his long-term academic trajectory at SSU. Unlike Joana's and Monica's cases, Frank experienced racially-conscious care via check-ins that initiated provisions of academic support for Latin* students, which facilitated his help-seeking readiness and campus connections for mathematical success.

Ofelia similarly reported supportive instruction that built a classroom community invested in her academically and personally. Her instructor's check-ins included office hour meetings with individual students as well as a peer accountability system for students to ensure each other's well-being and collaborate on groupwork after class, "She'll tell a student, 'Hey, reach out to your classmates and see what's going on'… She's [also] like, 'I encourage you to meet with your group… You guys could be in here working on it or go to the library.'" Ofelia viewed these check-ins reflecting racial consciousness for Latin* students' needs in light of how the instructor commented on limitations of servingness at SSU, "She said, 'In fact, Sonoma isn't really a Hispanic-serving college. They just say that… They are working on bettering." Such support through check-ins made mathematics less of a vulnerable experience as further described below.

Instructor support alleviated Ofelia's help-seeking tensions arising from Latin* cultural values, including orgullo and gendered scripts of behavior, "Pride is a very big thing [in Latin* culture] also tied in with the machismo… Women are very silent [and] don't voice what's going on. Even with men, you're supposed to be this tough person." Racially-conscious care via check-ins defused Ofelia's pressures of remaining silent and working through struggles alone. For instance, such support shaped Ofelia's comfort with attending office hours where she shared how on-campus racism and homophobia affected her mental health and assignment progress.

> She [instructor] noticed that I was kind of off and she was like, "Hey, you haven't done your work. What is going on?… I could help you. … If you need more time, just tell me."… At first, I was like, 'I'm not going [to office hours]'… [It was] a pride thing. If I go, it shows that I don't understand this and I'm dumb… It was a struggle with eating up my pride and going.

This check-in experience ultimately brought Ofelia to view office hours as a "safe space" where her struggles as a queer Latina were seen and accommodated to succeed. Her instructor's support disrupted the logic of mathematics as disconnected from social issues, thus enabling Ofelia to negotiate identity-related matters and mathematics coursework. By cultivating a classroom community that destigmatized help-seeking through check-ins (e.g., peer accountability norms, office hour meetings), the instructor promoted equitable support

opportunities for Latin* students like Ofelia that compensated for limitations of servingness across the broader SSU campus.

Cross-Case Analysis

The two case pairs portray how check-ins were perceived as gateway mathematics instructors demonstrating racially-conscious care that expanded support for Latin* students. Check-ins were responsive to the three levels of influence for instructional servingness (Figure 1). At the societal level (Figure 1a), a void of check-ins in Joana's and Monica's cases left them grappling with culturally-mediated tensions for help-seeking as well as wariness of judgment due to stereotypes and educational inequities. Instructor consciousness for Latin* student realities, including cultural values (e.g., familismo) and systemic racism (e.g., lack of campus resources), was seen as guiding support via check-ins across Frank's and Ofelia's cases. At the campus level (Figure 1b), check-ins allowed instructors to initiate the process of Latin* students receiving help, thus resembling campuswide servingness from SSU programs and offices that reached out to provide support as detailed elsewhere (Leyva et al., 2025). Check-ins relieved Latin* students of help-seeking pressures to ensure support for their mathematical success. At the discipline level (Figure 1c), check-ins resisted logics of social neutrality, individualism, and innate ability in mathematics education that preclude an equitable distribution of instructor support in classrooms.

With campuswide servingness connecting Latin* students to staff and peers who extended help for their success at SSU (Leyva et al., 2024), similar support through check-ins across Frank's and Ofelia's cases fostered collectivism by building support networks for mathematics learning. Such networks alleviated help-seeking tensions and embraced Latin* students' cultural value of communal support, thereby creating a racially-affirming community as a mechanism of instructional servingness (Figure 1d). Check-ins experienced as rooted in racial consciousness of Latin* students' social realities contributed to this mechanism for equitable support (Figure 1e).

Discussion & Implications for Future Research

Our report's findings make a threefold contribution. First, we extend research on racial equity in gateway mathematics instruction, which has articulated a general vision of equitable support with limited insights on practices for specific populations. We fill this gap by capturing how check-ins can defuse Latin* students' culturally- and racially-mediated pressures about seeking academic assistance. Second, this report's insights on check-ins add a novel dimension to studying equitable support in gateway mathematics that has focused on instructor responses to students' help-seeking. Our analysis distinctly portrays how instructor-initiated help via check-ins that exhibit racially-conscious care disrupts norms in undergraduate classrooms reproducing inequities of support. Check-ins can relieve Latin* students from needing to self-advocate for support, all while resisting dominant logics in mathematics education (e.g., individualism) and racialized forces (e.g., stereotyping) that exacerbate help-seeking vulnerability. Third, we respond to calls for exploring connections between Latin* students' experiences in gateway mathematics classrooms and broader HSI campus settings (Convertino et al., 2023; Ro et al., 2024). Our findings show how instructor support through check-in practices fostered continuity of racial equity from campuswide structures at SSU for instructional servingness in mathematics.

For future research, studies can explore (mis)alignment between instructor intent with check-ins and Latin* student experiences. This work can uncover how racial consciousness levels shape check-in approaches and the extent to which students view them as fostering equitable support (Gutiérrez et al., 2025; McNeill et al., 2022). Studies can also extend our analysis by examining how variation in HSI settings' campus resources and Latin* student demographics influence check-ins for instructional servingness. In addition, intersectional analyses of check-ins that

more explicitly consider Latin* students' other identities (e.g., disability) can further nuance insights on servingness in gateway mathematics. Such future lines of inquiry will shed light on the multiplicity of instructional servingness across HSI contexts and within the Latin* diaspora.

CONCEPTIONS OF EQUITY AMONG DISTRICT PERSONNEL THROUGH A JUSTICE LENS

We analyzed interviews conducted with school district personnel in the U.S. state of Missouri, in which participants were asked about equity-related challenges both in general and specific to mathematics. Applying Fraser's framework for justice, we analyzed each transcript for what individuals say needs to be made equitable (redistribution, recognition, or representation); who they describe disadvantaged by inequality in terms of race, class, disability, sexual orientation and gender identity, or emerging multilingualism; and what kind of change is necessary (transformative or merely affirmative). Results revealed variation in equity conceptions depending on the mathematics specificity for all three foci. We found that there were equity discourses present that did not penetrate the boundary of mathematics. Most striking is that almost all conceptions of mathematics-specific equity were limited to redistribution.

Keywords: Equity, Inclusion, and Diversity; Social Justice

Through its decades-long trajectory from the margins of scholarly interest, with only a relative few calling for a greater focus on it (e.g., Matthews, 1983; Secada et al., 1995), to a mainstream presence worthy of critiques from sympathizers within the field (e.g., Bullock, 2024; Chen, 2024), "equity" in mathematics education has been defined and pursued in multiple ways. Each is rooted in a set of logics that may vary in articulations of the goals of schooling (and school mathematics), underlying theories (e.g., from theories of learning to critical theories), and, consequently, emphasis on things like diversity, history, and justice. Among those whose definitions are oriented by more critical perspectives, a common concern is whether increased attention to equity in the field has had any effect beyond the surface, whether the status and school mathematics experiences of the historically marginalized have materially changed (Martin, 2019).

Some scholars have conjectured that equity ideas and practices that are unlikely to disrupt current power structures are more readily adopted than those that might threaten hierarchies organized by race, class, or other social dimensions. For example, in studies of mathematics teacher professional development efforts, Rubel (2017) as well as Wilson et al. (2019) observed teachers successfully employing equity-focused instructional practices that increased students' access to and success with important mathematics, but fewer instances of teachers' use of practices that were attentive to students' identities or power dynamics in the classroom—a distinction that Gutiérrez (2007) characterized as "dominant" vs. "critical." In a study of district policymaking in two different communities, Nguyen (2024) similarly found a presence of dominant equity ideas and an absence of critical equity ideas in leaders' discourses around mathematics education policy. However, given her interest in where and how the "boundary" of

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

mathematics education policy is framed, Nguyen also studied leaders' discourses beyond mathematics, where she did observe the presence of more critical equity ideas—ideas that Nguyen argued "did not penetrate mathematics" in part because of the ways that school mathematics was discursively constructed (p. 503).

In the present analysis we sought to more systematically examine equity discourses among school personnel both within and beyond school mathematics to gain insights into the ways and reasons that more critical discourses do not penetrate the boundary of school mathematics. To do so, we drew from extant work to develop an expanded framework rooted in Fraser's (2005) conceptualization of justice and specified in ways applicable to both education in general and mathematics education specifically.

Theoretical Perspectives and Literature Review

Attention to Discourse

The ways in which school district leaders make sense of and respond to challenges is consequential to maintaining or transforming education. Leaders' discourses—"language use around a particular socially and historically situated topic, which… corresponds to a particular position and perspective"—about their challenges reflect and shape whether and how they implement initiatives and policies (Bertrand et al., 2015, p. 3). Informed by critical discourse analysis (CDA) (Rogers, 2011; Fairclough, 2015), we understand discourses employed by district leaders—who are in positions of leadership tasked with writing and implementing educational policies—as both reflecting and constructing power relations (Anderson & Mungal, 2015).

Discourses cannot be understood apart from the social contexts in which they circulate, and the ways in which people employ discourses are influenced by broader ideologies, including those related to race and class (Fairclough, 2015). That is, discourses are not neutral; they compete for power and recognition (Fairclough, 2015; Rogers, 2011; Gee, 2014). CDA helps to reveal the dominant ideologies masked by seemingly neutral language, policies, and practices to explore the ways in which discourses gain power.

Orientation to Equity

Within that view of discourse, we understand "equity" to be, as Apple (1995) characterized it, a "sliding signifier"—a term not with "essential meaning," but "defined by [its] use in real social situations with real relations of power" (p. 335). An examination of equity discourses among school district personnel therefore requires a sufficiently expansive framework to capture the various conceptions of equity—both in general and in ways specific to school mathematics—that might be circulating. In our view, it must account for *what* individuals say needs to be made equitable; *who* they describe as currently, historically, and/or potentially disadvantaged by inequality; and *what kind of change* is necessary to achieve equity.

Initially, we tried to apply recent frameworks for characterizing conceptions of equity among school district personnel, including Roegman et al.'s (2022) conceptions of equity among school principals; Farrell et al.'s (2023) conceptions of equity among research-practice partnerships; and the National Academies of Sciences, Engineering, and Medicine's (NASEM; 2024) five frames for decision-making in STEM education. Each of these had merits, but none was sufficient for our needs—either because it was not applicable to both general and mathematics education or because it was not helpful in distinguishing different kinds of proposed changes.

Ultimately, we found resonance in Fraser's (1995, 2005, 2009) three-dimensional conceptualization of remedying injustice (or, *what* needs to be made equitable): redistribution, recognition, and representation. Redistribution refers to the distribution of goods in response to

socioeconomic injustice. Recognition attends to "existing identities that are currently undervalued" in response to cultural or symbolic injustices such as cultural domination, non-recognition and/or disrespect (Fraser, 1995, p. 73). Representation foregrounds "procedures that structure public processes of contestation" in response to political injustices such as the exclusion of minoritized individuals from decision-making processes and/or the maintenance of hierarchies privileging individuals belonging to dominant social groups (Fraser, 2009, p. 17).

According to Fraser, remedies to injustice are also concerned with *who* is or has been affected by the injustice and/or to whom justice should apply. In addition to describing *what* needs to be made equitable and *for whom* inequity should be addressed, Fraser articulated two responses to injustice (or, in our terms, *kinds of change*). *Affirmative* responses to injustice reaffirm the differences between social groups (e.g., multiculturalism). *Transformative* responses acknowledge that differences are socially constructed and attend to the structures that draw distinctions between social groups (e.g., mechanisms of tracking that create a hierarchy of ability).

In recent years, Fraser's remedies of injustice have been increasingly applied in mathematics education research (Vithal et al., 2024). For instance, Fraser's tenets have been employed to study (a) patterns of marginalization for refugee students across multiple levels of education (recognition) (Keddie, 2012), (b) disparities in learning opportunities due to inequitable resource allocation (redistribution) (Taylor et al., 2024), and (c) mathematics teachers' perspectives on "*who* decides on *what* schooling for *whom*, and *how*" (representation) (Meaney et al., 2022, p. 560). The present study adds to this body of literature, with attention to general and mathematics-specific contexts in the discourses of various educational constituents.

Attending to Mathematics

Despite increased attention to equity, mathematics education reform has been characterized by enduring inequality and the largely unchanging nature of the status and experiences of the historically marginalized. Some have suggested school mathematics may be especially aligned with hegemonic discourses and the ideologies undergirding them (Llewellyn & Mendick, 2011) and, thus, may resist meaningful change, protecting the interests of the dominant class (Martin, 2015). Others have pointed to aspects frequently attributed to mathematics itself (e.g., neutrality, numbers, objectivity) and posit that those discourses, rooted in dominant ideologies of neoliberalism and neoconservatism, act as a barrier around school mathematics, leaving it immune/untouched (e.g., Kinder et al., 2024). Still others suggest that mathematics itself is to blame, pointing to the inextricable role of mathematics in capitalism (Apple, 2000) and white supremacy (Battey & Leyva, 2016; Stinson, 2017). This warrants attention to school mathematics itself. Given Nguyen's (2024) suggestion that the discursive construction of school mathematics prevents penetration of critical discourses in school mathematics, there is reason to believe we should attend to discipline-specific conceptions of equity.

To this end, in our analysis, we are concerned with the conceptions of equity among those designing and implementing equity initiatives. In particular, we are concerned with how those conceptions differed when talking about school mathematics. Our analysis was oriented by the following research question: What are the conceptions of equity among school district personnel, and how do those conceptions vary across descriptions of mathematics-specific and general equity initiatives/concerns?

Methods

Data Collection

To answer our question, we analysed interviews conducted during the 2023-2024 academic year as part of an effort to understand equity-related challenges, goals, and initiatives in rural school districts. We partnered with a single rural district in Missouri, a state in the central region of the U.S. The district is situated in a community with approximately 20,000 residents, 80% of whom are white (U.S. Census Bureau, 2020).

For the current analysis, from the 38 semi-structured, 45-minute interviews conducted in the larger project, we identified those that mentioned both (a) general equity challenges and (b) equity challenges specific to school mathematics. This resulted in 12 interviews, including two district leaders, eight school leaders—two of whom were interviewed together, accounting for a thirteenth participant—and three teachers.

Data Analysis

We began analysis by organizing interview transcripts into stanzas (Gee, 2014) and identifying stanzas in which participants described an equity-related challenge. This resulted in 145 stanzas, with 10.75 stanzas, on average, in each interview (range 4-18).

Type of Discourse	Redistribution	Recognition	Representation
Transformative	(a) Identifies structural barriers to an equal distribution of goods and/or (b) promotes initiatives that would shift such distribution.	(a) Identifies sources that promote narratives of "normality" (e.g., race, heteronormativity, etc.) that contribute to maintaining higher status and privilege for some groups and/or (b) employs narratives that suggest the social construction of identity (e.g., gender as a construct, racism as foundational to race)	(a) Identifies structures or practices that maintain hierarchies of power that elevate some voices and limit others and/or (b) promotes processes that would shift the current power structure
Affirmative	Acknowledges differences in opportunity *between social groups*; promotes equal access, without attending to structural barriers	Recognizes patterns of exclusion that contribute to maintaining higher status and privilege for some groups, but falls short of acknowledging the sources contributing to the injustice	Recognizes the need for voices of minoritized social groups to be included in the decision making of educational issues
Evasive	Does not acknowledge an injustice in the distribution of goods; raises no concerns about the status quo	Fails to attend to the identities of minoritized social groups and the injustices and/or differences associated with those identities	Does not acknowledge an injustice or inequality in decision-making power or processes
Anti-equity	Promotes/agrees with ideas or actions that contribute to an unequal distribution of goods	Promotes/agrees with ideas or actions that contribute to an unequal recognition of social identities	Promotes/agrees with ideas or actions that contribute to an unequitable distribution of decision-making power

Note: The codes were employed to characterize the participants' discourses within any named social groups (i.e., race, class, gender, LGBTQIA+, ability, multilingual status, personality/behavior)

Figure 1: Analytical Framework

We coded each stanza for (1) the named social group(s) (e.g., race, class, gender, sexual identity, ability); (2) whether each challenge the participant named was within or beyond school mathematics; (3) the dimension of the named injustice (i.e., maldistribution, misrecognition, misrepresentation); and (4) the type of discourse. Within the first of those, named social group(s), we separated responses regarding gender into two categories—those that constructed a

gender binary (e.g., comparing girls' opportunities to those of boys) and those that concerned gender non-conforming students, which we combined with sexual identity ("LGBTQIA+"). For the final code, we identified four "types" of discourse: those aligned Fraser's (1995) "transformative" and "affirmative" approaches to justice, those that were overtly "anti-equity" (NASEM, 2024), and a fourth type resulting from our analysis, descriptions that were "evasive," where the participant did not raise concerns about the status quo with respect to injustice or inequality (Bonilla-Silva, 2006; Annamma et al., 2017). In Figure 1 we define each type with respect to each of Fraser's remedies to injustice. If we determined the participant's equity discourse was not a response to an injustice, but the participant still named an equity challenge, we coded the stanza as a "response to diversity." Using the framework in Figure 1, interviews were coded independently by at least two authors. Discrepancies were resolved collaboratively until agreement was attained. We compiled our analyses to identify themes in the participants' discourses across social constructs and role groups.

Findings

Figure 2 provides a summary of the results of our analysis. Perhaps unsurprisingly, discussion of equity was roughly four times more frequent for "non-math" topics than for those specific to mathematics. But our analysis revealed considerable variation in participants' equity conceptions depending on the mathematics specificity. This was the case with respect to all three of our foci: the dimension of injustice; the named social group(s); and the type of discourse (or kind of change promoted).

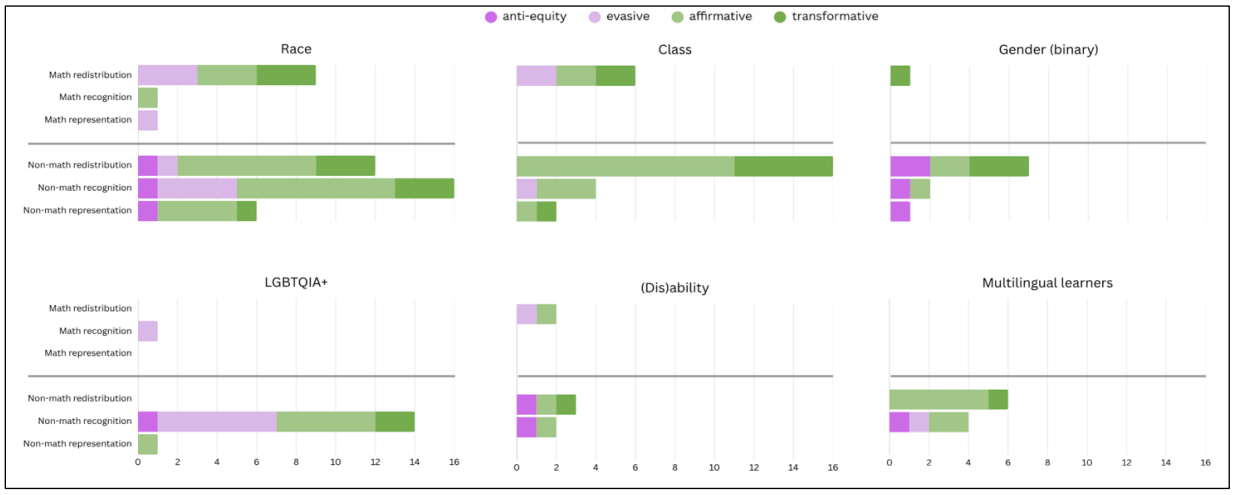

Figure 2: Coding Results

Regarding the "who" of participants' concerns, race and class were most frequently invoked. With respect to class, redistribution was the most prominent justice dimension within non-math areas, and the only dimension in conceptions of mathematics-specific equity. And evasive types of discourse were more present in discussion of mathematics (e.g., "our number one area of concern is just number sense… and our kindergarten readiness reports, those kiddos that come in not knowing anything," which the participant, when asked, associated with socioeconomic status). General equity talk about race was more distributed across Fraser's dimensions, with recognition being the most frequent. It also spanned all types of discourse, from transformative

to anti-equity. But within mathematics, conceptions of equity and race were almost exclusively about redistribution, with no transformative discourse about recognition or representation.

Among the other social groups, there were very few instances of talk that were specific to mathematics. There was considerable discussion of LGBTQIA+ students, but almost exclusively along the dimension of recognition and only once in the context of mathematics ("In math, we kind of work with the numbers and the x's...and maybe not as concerned about your feelings"). Additionally, as illustrated by the previous quote, we found the highest rate of evasive discourses was about this social group. While half of the participants discussed equity for multilingual learners in general (regarding redistribution and recognition, but not representation), none mentioned mathematics-specific issues. And only a few participants invoked (dis)ability, including two mentions of mathematics-specific issues, both about redistribution. In addition to the six social groups already noted, very few participants raised equity concerns related to different "personality" or "behaviour" needs among students—all with affirmative discourses except for one instance of transformative discourse.

Lastly, in four of the interviews we identified a conception of equity framed by responses not to injustice or inequality, but to diversity. Most were related to notions of "ability." For example, one school leader explained, "we decided to do flex math groups… ability grouping, you could call it… our data suggests that we have kids all over the place, and we need to meet those individual students' needs. So, we have six third grade teachers, and we took our data and broke it up into six groups." This is not to suggest that such categories would not lead to inequality or injustice (Domina et al., 2023), only that some participants conceived of equity as attending to differences in students' current understanding and learning "needs."

Discussion

Our results suggest conceptions of equity among school personnel vary between considerations of education in general and mathematics education in particular. Specifically, we found the presence of equity discourses that did not penetrate the boundary of mathematics (Nguyen, 2024). Most striking is that almost all conceptions of mathematics-specific equity were limited to redistribution. This result could be interpreted as echoing previous findings by Rubel (2017) and Wilson et al. (2019) that teachers were more likely to attend to issues of achievement and access than to issues of identity and power—a division that Vithal et al. (2024) mapped onto Gutiérrez's (2007) *dominant* and *critical* axes, respectively.

However, Fraser's distinction in types of discourse is helpful here: the transformative ways of describing redistribution we observed suggest that critical conceptions of mathematics-specific equity were present among district personnel, as some advocated for dismantling structures that give rise to inequality rather than an affirmative promotion of merely more equal distribution within those structures. This suggests that the absence of matters of recognition or representation in participants' conceptions of mathematics-specific equity should not, necessarily, be interpreted as resistance to critical orientations, but could be attributed to other factors, including the local construction of the subject matter context (Grossman et al., 2004; Nguyen, 2024). It is possible that other factors may also have contributed to the absence of attention to LGBTQIA+ students and multilingual learners in mathematics-specific ways.

We might pause to consider, however: what would we consider "ideal" conceptions of equity? Would it be transformative discourses attending equally to all three dimensions of justice for each social group? Or might we expect conceptions to vary across contexts as they respond to local histories and circumstances? While our study presents a framework for accounting for multiple aspects equity conceptions, it does not provide any empirical basis for considering what

might be "ideal" or "best." While we are doubtful that such a claim could be possible (or even appropriate) to pursue, we do imagine that future research could help explain more of the variation we observed.

PEDAGOGICAL ACTIVISM IN MATHEMATICS EDUCATION: ARMED LOVE AND COMMUNITY CULTURAL WEALTH

Casedy Ann Thomas

Robert Q. Berry III.
Indiana University
rqberry@iu.edu

In mathematics education, scholars often attend to the complexities of teaching and learning in socio-cultural contexts, but far too often, they fall short of developing a deep understanding of the history that informed such contexts. While we must look to history to understand the ripple effects of such unjust systems, we must also look to powerful historical examples of pedagogical activism to understand how we can better link research and practice to serve historically marginalized learners today. In this oral history, we document how 12 Black K-12 mathematics teachers during the American Civil Rights Movement engaged in pedagogical activism by creating protective factors for their learners, drawing on armed love and community cultural wealth. This study advances our understanding of how to operationalize critical pedagogies in mathematics and build more equitable mathematics instruction by looking to the past.

Keywords: Culture and Asset-Based Pedagogies; Equity, Inclusion and Diversity; Identity and Agency; Social Justice

Problem Statement and Conceptual Framework

Our hopes for mathematics instruction are rooted in its potential to serve as a tool for liberation, cultural affirmation, and the development of critical consciousness. Although mathematics is often perceived as neutral or apolitical, it holds transformative power when contextualized within teachers' and students' lived experiences and histories. We envision mathematics instruction that not only supports conceptual understanding (Lampert et al., 2010) but also affirms identity (Aguirre et al., 2024), fosters agency, and builds bridges between learners, their communities, and the broader world. We look to historical forms of pedagogical activism (Alridge et al., 2023) to better understand how teachers drew upon armed love and community cultural wealth (CCW) to create protective factors for learners in mathematics.

Armed Love

Armed love is not soft or lacking in power; rather, it is a "political and radicalized" form of love "rooted in a committed willingness to struggle persistently" toward our true purpose—to be human (Ares et al., 2024; Darder, 2002, p. 34). While armed love has been researched across contexts (e.g., Lanas & Zembylas, 2015; Stern & Brown, 2016; Bartolomé, 2004), in critical pedagogy (Ladson-Billings, 2021) and pedagogical activism, it is discussed as drawing upon shared experiences and critically conscious care (Ares et al., 2019; 2024).

Community Cultural Wealth

When teachers practice armed love that builds upon CCW, they create protective factors for historically marginalized learners (Ares et al., 2024; Zoch & He, 2020). CCW is a community's cultural resources, not unlike funds of knowledge, to help learners to challenge oppression from a place of strength and knowledge (Ares et al., 2024). However, unlike other works that focus on assets developed by communities, CCW "expands on traditional notions of capital to identify those that are often found in non-dominant communities under pressure" (Ares et al., 2024, p. 2932; Yosso, 2005). CCW includes six forms of capital: familial, aspirational, navigational, resistant, social, and linguistic. Learners and families often use such capital to help them to

navigate challenges and resist exclusion in social spaces controlled by dominant cultural norms, as seen within the American educational system. What is less clear is how teachers from non-dominant communities incorporate the six forms of capital and armed love to build critical pedagogies in mathematics education. To further examine this work, we looked to history and Black mathematics teachers who engaged in pedagogical activism by showing acts of love and enacting capital-rich practices during the American Civil Rights Movement.

Methods

As Research Associates of the Teachers in the Movement Project, we conducted a secondary analysis of 12 oral history (Ritchie, 2015; Alridge et al., 2023) interviews collected with Black, former mathematics teachers who taught K-12 during the American Civil Rights Movement. These educators, primarily located in the American South, shared their experiences teaching mathematics amid the social and political upheaval of the era. Consistent with oral history methodology, participants' identities were retained to preserve historical attribution and to honor participants' contributions. All interviews (approximately 60 minutes each) were video-recorded, transcribed, and verified through member checking to ensure historical accuracy. Our analysis involved coding transcripts at the stanza level (Saldaña, 2013) and composing analytic memos to address our central question: How did these teachers engage in pedagogical activism with their students in mathematics? Specifically, we wanted to understand the protective factors behind such pedagogical activism. Our codebook was developed using a combination of deductive and inductive coding (Corbin & Strauss, 2015), drawing upon critical pedagogies (Ladson-Billings, 2021), armed love and CCW (Ares et al., 2024).

Pedagogical Activism Built Upon Protective Factors

Armed Love & Critically Conscious Care

While many of the teachers did not necessarily consider themselves Civil Rights activists, their accounts of pedagogy display central tenets of pedagogical activism. Their classrooms were spaces where care, resilience, and resistance intertwined, reflecting *caring as resistance* (Ladson-Billings, 1994) or critically conscious care (Ares et al., 2024). By enacting rigorous yet compassionate teaching, Black educators created protective factors designed to safeguard students from the dehumanizing effects of racism and discrimination. Oliver captured this ethos when she explained, “You don’t have to talk it, but you need to act it. I think that I did not do a lot as far as the movement was concerned except that I tried to practice certain things [in my teaching].” In this sense, teaching itself became activism—every lesson, every act of care, every insistence on students’ potential constituted resistance in a world that routinely denied Black children intellectual and social legitimacy (hooks, 1994). Such care was continually interacting with the six forms of capital within CCW. Figure 1 is the authors’ conceptual model of protective factors building pedagogical activism, developed from analysis of the oral history findings.

Familial Capital

Familial capital reflected armed love through relational accountability, as teachers positioned themselves as trusted community members who shared responsibility with families for students’ academic, social, and moral development. Their commitment extended beyond classroom instruction, creating networks of care and high expectations that protected students from dehumanizing societal messages while affirming their worth and potential. The teachers often made connections to their own educational experiences in shaping their perceptions of who should be stakeholders in students’ learning as well as what learning communities should look

like. For example, the teachers discussed the extent to which their own teachers were involved in their community and their learning as familial figures. Goode stated, “it wasn't like a call home or stuff [like] that they’d walk over to your house.” Benjamin echoed these same sentiments, saying, “you saw the teacher at church, and you did not want your parents to have a parent conference at church.” Brown discussed how this sense of community created more opportunities for the teachers to hold the learners accountable to high expectations, both behaviorally and academically. Gordon stated that they relied on their teachers for “nurturing and care in love and guidance and our parents really trust the school system to take care of us”. The teachers saw this familial capital as integral to students’ mathematical learning.

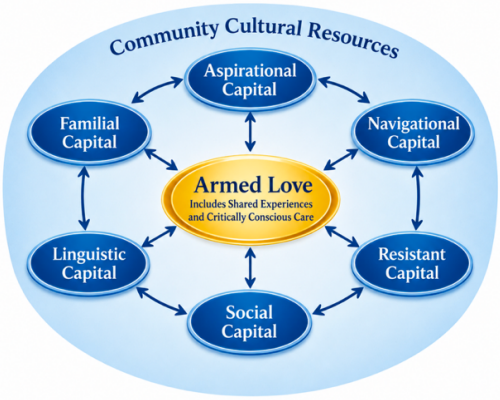

Figure 1: Protective Factors Building Pedagogical Activism

Aspirational Capital

Aspirational capital embodied armed love through teachers’ deliberate cultivation of future possibilities for Black learners. By encouraging self-advocacy, exposing students to successful role models, and nurturing beliefs in their own capabilities, teachers enacted a radical form of care that challenged limiting narratives and helped students envision futures beyond the constraints imposed by racism and social inequities. Goode stated, “I would do the very best I can for my students, plus … I also want them to advocate for themselves. So, I give them the tools that they need to advocate for themselves.” Gordon spoke of how Johnson, who was her math teacher, was influential in stressing these ideals in his instructional strategies. One practice that Gordon noted as being impactful was bringing former students back to the classroom who had obtained careers that her students aspired to obtain [especially in STEM] because as a student herself, “seeing individuals who are successful, who started the same way as me, gave me hope.”

Social & Navigational Capital

Social and navigational capital embodied armed love through teachers' intentional efforts to equip students with the knowledge, skills, relationships, and resources necessary to navigate educational and societal structures not designed for their success. Through ambitious mathematics instruction, mentorship, and access to networks of support, teachers helped students develop both mathematical competence and the confidence to maneuver through spaces shaped by racism and exclusion. Their commitment to ensuring students understood mathematics deeply and recognized their own intellectual capabilities represented a radical form of care that protected students' identities while expanding their opportunities for participation and success. For example, Johnson discussed how he “ma[de] sure that everyone had a conceptual grasp of

the content" and Gordon noted that it was about helping students to "understand the why" behind the procedures. Lewis discussed the importance of rooting mathematics in lived experience and future goals, and how his father's work as a handyman influenced his pedagogy that focused on hands-on visual applications. "So sometimes it might have been taking a [soup] can … [and] have a pair of tinsnips and cut it down the middle and lay it out. You've got a rectangle, you know, just so they could visually understand some of the things you were talking about." Lewis went on to discuss the importance of dispelling myths about who could or could not "do math", which was also a deliberate protective stance.

Resistant Capital

Resistant capital illustrated armed love through the development of critical consciousness and collective struggle against injustice. Teachers encouraged students to recognize, question, and challenge inequitable structures while equipping them with the intellectual tools necessary to navigate and transform those conditions. In doing so, they demonstrated a form of love grounded in liberation, empowering students to see themselves as capable agents of change rather than passive recipients of oppression. One of the most profound examples was when Langston discussed bias assessment practices in the '67, '68, and '69 school years (prior to integration). The segregated Black school, Emmett Scott, performed better on standardized mathematics tests than the White school, Rock Hill. Langston noted, "…we beat Rock Hill in every category, and they didn't like that because we were Black, and so we had to go back and take this test over." He went on to discuss how, after the retake, the Black students still performed better in every individual component and how he discussed these issues to build consciousness with his learners. The teachers had their own definitions of Civil Rights; some, like Edwards, extended discussions to present times, adding "But we are in an ongoing struggle, and that has become very evident to us in this very, very recent past."

Linguistic Capital

Linguistic capital reflected armed love through teachers' affirmation of students' cultural and communicative ways of knowing while simultaneously preparing them to navigate dominant linguistic norms. By valuing the language practices, storytelling traditions, discourse patterns, and cultural expressions of Black communities, teachers created spaces where students' identities were respected rather than erased. This form of care was not merely affirming; it was protective and empowering, equipping students with the linguistic flexibility needed to thrive across multiple contexts while maintaining connections to their communities and cultural heritage. In all Black schools, with all Black students and teachers, such cultural competency looks different than how it is discussed in literature post integration; thus, it expands upon our understandings of how teachers integrate cultural knowledge and practices into their mathematics instruction to create meaningful and relevant learning opportunities for their students (Thomas & Berry, 2019).

Discussion & Conclusions

Across the six forms of capital, armed love functioned as a protective force that affirmed students' humanity, nurtured their identities, expanded their possibilities, and prepared them to navigate and challenge oppressive conditions. In this way, pedagogical activism was not simply about teaching mathematics; it was about leveraging CCW to cultivate liberation, agency, and flourishing. This study contributes to the growing scholarship on Black educators' roles during the Civil Rights Movement, particularly in mathematics education. The teachers' recollections offer critical insights for today's educators, especially amid renewed resistance to culturally responsive education and critical pedagogies. By preserving and learning from these histories, we can better understand how teachers created protective factors in mathematics, drawing upon

armed love and the CCW of non-dominant communities under pressure (Ares et al., 2024). Likewise, we can further understand how to best support Black learners with identity-affirming mathematics instruction and reimagine mathematics education as a site of liberation and joy.

TRANSFORMING PRESERVICE TEACHERS' MESSAGING THROUGH MATH NARRATIVES IN MIXED-REALITY SIMULATIONS

Liza Bondurant

Keywords: Affect, Emotion, Beliefs, and Attitudes; Equity, Inclusion, and Diversity; Preservice Teacher Education; Technology

Beliefs about mathematics shape students' identities, engagement, and opportunities to learn. Unproductive math narratives (MNs) can limit students' participation and persistence. This poster reports on a multi-institutional project examining how structured preparation and mixed-reality simulation (MRS) can support preservice secondary mathematics teachers (PSTs) in communicating productive MNs. RQ: How does engaging in preparation and MRSs influence PSTs' self-efficacy and messaging related to the MNs of: (1) encouraging help seeking, (2) making mathematics relevant, and (3) affirming the value of mistakes?

Theoretical Perspectives

The project is grounded in sociocultural and social constructivist perspectives that position learning as relational and discourse-driven. Drawing on Complex Instruction, we conceptualize help-seeking as a collaborative practice that redistributes intellectual authority across the classroom (Cohen & Lotan, 2014). Efforts to make mathematics relevant align with calls for instruction that prepares students for participation in college, careers, and civic life (Aguirre et al., 2013; Moses & Cobb, 2001). Affirming mistakes reflects research demonstrating that struggle can support learning and identity development (Boaler, 2022; Jansen, 2020). PSTs' visions of ambitious instruction inform how they enact the MNs (Munter, 2014).

Methods

Mathematics Teacher Educators (MTEs) attended a BranchED professional learning conference introducing the Math Narratives Project (n.d.), a Gates Foundation-funded mixed-methods study of U.S. secondary students' mathematical identities. During Spring 2026, PSTs in the MTEs' methods courses completed three phases designed to contribute to shifts (Self & Stengel, 2020) in their MNs (Gutiérrez et al., 2023). In the Prepare phase, PSTs completed belief and self-efficacy surveys and a reflection tool articulating their visions for practice. During the Intervention phase, PSTs analyzed materials on MNs, planned a short lesson integrating the three focal MNs, and prepared for an MRS (Bondurant & Amidon, 2021; Bondurant & Reinholz, 2023; Colonnese et al., 2024; Lee et al., 2025). During the MRSs, PSTs practiced enacting the three focal MNs. In the React-Review-Reconsider phase, PSTs composed reflections, analyzed video recordings of their teaching, and completed a post-survey.

Preliminary Findings

Data sources include pre/post belief measures, self-efficacy ratings, written reflections, and MRS artifacts. Quantitative analyses will examine shifts in PST beliefs, while qualitative analyses will identify patterns in how PSTs interpret and enact MNs. Preliminary findings suggest PSTs became more intentional and confident in communicating productive MNs.

Acknowledgments

We would like to thank BranchED for the professional learning that made this work possible.

"Authentic thinking, thinking that is concerned about *reality*, does not take place in ivory tower isolation, but only in communication" (Freire, 1970/2004, p. 77). Through a critical autoethnography lens (Boylorn & Orbe, 2021), this poster presentation reflects our experiences of continually confronting our realities as new mathematics teacher educators. Our participation in an early career induction program for teacher educators in mathematics education initially shaped our communication. In our attempts to transcend the traditional isolation of academia, we sustained supportive dialogues grounded in the works of bell hooks and Paulo Freire. As mathematics teacher educators who support preservice teachers in their preparation programs, we started by meeting regularly to read and discuss *Teaching to Transgress* (hooks, 1994) and *Pedagogy of the Oppressed* (Freire, 1970). These meetings functioned as an intentional counter-space within the academy—one that invited vulnerability, dialogic engagement, and sustained critical reflection. Through collective reading, discussion, and reflection, we worked to surface how our lived experiences, despite coming from varied cultural, professional, and personal backgrounds, have been shaped by what Freire (1970) critiques as the *banking* system of education and continue to impact our work as mathematics teacher educators. While we welcomed the complexity of our lived experience, we supported each other in navigating the institutional and societal constraints through liberatory pedagogies (hooks, 1994) and leaning into the discomfort of unlearning the banking system of education (Freire, 1970). Liberatory pedagogies and parting away from the banking system of education in our academic spaces while honoring our uniqueness has led to a necessary *praxis* (Freire, 1970)—reflection and action in dynamic relation. This praxis involved a fracturing of self within a liminal space where we are in the midst of changing, leading to a recognition that *becoming* demands relinquishing familiar identities and certainties. This praxis resonated with what Anzaldúa (2012) describes as *nepantla*—in-between spaces of tension, ambiguity, and transformation—and how Freire (1970/2004) unpacks these spaces "as an uncompleted being conscious of their incompletion" (p. 43).

Whether through the continual reflection of our identities as women with diverse cultural lived experiences, the fracturing of our identities as we are undone and remade within academia, or through connecting to poetic memories, our small collective of mathematics teacher educators continues to make strides in understanding who we are and the power of injecting our voices into existence. Through reflection on our practices, we become conscious beings, constantly unveiling the reality that occurs with communication. As beings in this process of becoming, we became conscious of our incompletion, آن کس که بداند و نداند که بداند, of the need for constant transformation. This poster presentation shares our experiences in developing a community-based praxis in mathematics education to support the transition into teacher education and

explores how our collective learning and reflection have enhanced the ways we support our preservice teachers.

REFRAMING PRODUCTIVE STRUGGLE AS INCLUSIVE STRUGGLE FOR LEARNERS WITH DISABILITIES IN SECONDARY MATHEMATICS

Totrina L. Mosley
Belmont University
trina.mosley@bruins.belmont.edu

Keywords: Equity, Inclusion, and Diversity; High School Education; Students with Disabilities

High school mathematics courses taught in accelerated formats compress a full year of content into a single semester, often prioritizing coverage over depth (Cooke, 2024; National Council of Teachers of Mathematics [NCTM], 2014). Research reports mixed outcomes and reduced opportunities for sense-making and reflection (Young et al., 2024). Learners with disabilities (LWD) are especially underserved, as rigid pacing and deficit-based practices restrict meaningful opportunities for productive struggle (Comstock et al., 2022; Lambert et al., 2018). In constrained environments, instructional feedback becomes a critical lever for meaningful engagement. This study asks: How can instructional feedback support productive struggle for LWD in compressed-pacing mathematics classes?

Method

A conceptual synthesis approach (EPPI-Centre, 2010) integrates three theoretical constructs: Zone of Proximal Development (Vygotsky, 1978), Universal Design for Learning (Catama, 2025), and Rights of the Learner (Kalinec-Craig, 2017). These constructs map to the core dimensions of agency, authority, and belonging. Using this synthesis rather than empirical data, this study develops the *Instructional Feedback for Inclusive Struggle* (IFIS) framework. IFIS reframes productive struggle as inclusive struggle, defined as cognitive challenge supported through feedback that affirms identity, access, and participation (Mosley & Fox, 2026).

Findings

This poster presents a visual crosswalk showing how IFIS aligns with the five strands of mathematical proficiency (National Research Council, 2001) and its core dimensions (Mosley & Fox, 2026). Derived from the conceptual synthesis, findings identify key feedback strategies that support LWD, including dialogic feedback (supporting authority), cognitive scaffolding (supporting agency), and visual supports and problem-based learning structures (supporting belonging) (Tarmizi & Bayat, 2012; van Zee & Minstrell, 1997). When intentionally designed, these strategies sustain adaptive reasoning and productive disposition while fostering identity-affirming routines (Marita & Hord, 2017). By centering agency, authority, and belonging, IFIS promotes equitable mathematics instruction.

Implications

This work rehumanizes LWD in conversations about productive struggle and equitable, rigorous instruction. While not drawing on student data, this framework builds on scholarship that centers the experiences of learners with disabilities. Unlike deficit-oriented approaches that often reduce cognitive demand, IFIS positions feedback as a tool for sustaining rigor while expanding access to meaningful participation and affirming students' identities (Lambert et al., 2018). It also offers actionable strategies for teacher preparation and professional development for educators committed to equity-centered mathematics learning.

A RATIONAL CHOICE: WHY MATHEMATICS EDUCATORS CHOOSE NOT TO PUBLISH IN HIGH-IMPACT JOURNALS OF MATHEMATICS EDUCATION

Modiu Olaguro
Virginia Tech
olaguro@vt.edu

Tracy Proffitt
Virginia Tech
tprof8@vt.edu

Keywords: Equity, Inclusion, and Diversity

High-impact journals of mathematics education (HIJMEs) such as ESM, JRME, and MTL are often treated as elite, desirable outlets (Andrade-Molina et al., 2020; Nivens & Otten, 2017). Yet even accomplished scholars do not always pursue them. This poster examines why some researchers may not be inclined, motivated, or ready to submit to HIJMEs, despite being active publishers. Guided by Bourdieu's theory of practice, academic publishing is conceptualized as a competitive field in which access depends on economic, social, and cultural capitals (Bourdieu, 1972). HIJMEs thus function as spaces where dispositions such as confidence, linguistic sophistication, visible networks, and Western-aligned methodologies are rewarded. Fanon's psychoanalytic lens (1961, 1967) complements this framing by explaining how repeated exclusion and symbolic hierarchies produce avoidance, resignation, or self-doubt. Following this, our aim is to provide answers to the following questions:

1. What reasons do mathematics education faculty give for not attempting or prioritizing publication in HIJMEs?

Three senior mathematics education faculty were interviewed. Thematic analysis (Braun & Clarke, 2006) used deductive codes based upon capital (economic, cultural, social), habitus (identity, motivation, affect), and field norms; and inductive codes on emergent themes related to institutional expectations, intended audiences, and emotional labor. Although the data revealed key findings on field and capital deficits, we found that not publishing in HIJMEs was often a rational and strategic academic choice, not necessarily a sign of disinterest or incompetence. Participants described: (1) Restricted audience: Research on constructs such as self-efficacy may enjoy wider readership in educational psychology and broader education journals, making HIJMEs secondary outlets. (2) Professional logic: Faculty may delay HIJME attempts until promotion pressures are reduced, since institutional requirements to publish internationally can be met in less competitive journals. (3) Institutional indifference: Some higher institutions only require local journal and conference publications, reducing incentive to pursue HIJMEs. (4) Psychological aftermath: Faculty may avoid HIJMEs due to mental strain, fear of rejection, or anticipated bias—echoing Fanon's claim that exclusion generates internalized marginality. (5) Limited visibility: Because their work uses Nigerian samples, local researchers' lack of access to HIJMEs means their intended primary audience cannot read, use, or cite their research.

Therefore, rather than framing absence in HIJMEs as apathy or incompetence, these findings reveal a coherent logic of scholarly decision-making shaped by capital, habitus, and psychological experience, not merely exhortations to "publish higher."

FACTORS INFLUENCING RECRUITMENT OF WOMEN INTO SECONDARY MATHEMATICS TEACHING CAREERS

Xorlali Tsatsu
University of Nevada, Reno
xtsatsu@unr.edu

Lynda R. Wiest
University of Nevada, Reno
wiest@unr.edu

Keywords: Equity, Inclusion, and Diversity; Gender; High School Education

Objectives of the Study

This purpose of this scoping review was to examine factors influencing recruitment of women into high school mathematics teaching careers.

Conceptual Framework

Women might be dissuaded from becoming secondary mathematics teachers for several reasons. Zhou and Liu (2023) note, "Societal expectations, family influences, gender bias, and discrimination are influential factors that can impact career development" (p. 16). Stereotypes about mathematicians in general and about women in mathematics, including perceptions that men are more likely to be mathematics teachers and that women teachers teach lower-level content than men, might negatively impact women's decision to enter mathematics-oriented fields (Gjøvik et al., 2023; Rossi et al., 2022). College mathematics can also contribute, given that secondary mathematics teacher preparation requires substantial mathematics coursework (Winsor et al., 2018). In addition to being subject to sexist comments (Ogbuanya & Ogbuefi, 2025), women in STEM can experience college STEM environments that are individualist, competitive, and intimidating, with discourses of difficulty that cause self-doubt (Parson & Ozaki, 2017). A greater number of women students and teachers can be one factor that can favorably influence women in STEM (Bowman et al., 2022).

Methods

Guided by the Arksey and O'Malley framework and reported in line with PRISMA-ScR guidelines, a systematic search was conducted across five academic databases (Scopus, ERIC, Web of Science, JSTOR, and Google Scholar) for studies published between 2000 and 2025. Following screening and eligibility assessment, 19 studies were included in the review.

Results

This study shows that recruiting women into high school mathematics teaching is shaped by interconnected societal, institutional, and psychological barriers, which include gender stereotypes, limited access to female role models, institutional biases in recruitment pathways, mathematics anxiety, and a weaker professional identity. Promising interventions, including mentorship programs, targeted financial support, and institutional reforms, show potential for improving women's representation.

Discussion and Conclusions

This review contributes to mathematics education research by listing key constraints and supports that can influence women's recruitment into high school mathematics teaching and offering evidence-informed directions for policy, practice, and future research. This is an equity imperative and an important step toward enriching mathematics education.

MORE IS NOT ALWAYS BETTER: DGS INTERACTION TYPE AND DEDUCTIVE GEOMETRIC REASONING THROUGH EMBODIED COGNITIVE PATHWAYS

Doy Kim
University of Wisconsin-Madison
doy.kim@wisc.edu

Kelsey E. Schenck
Southern Methodist University
keschenck@smu.edu

Candace Walkington
Southern Methodist University
cwalkington@smu.edu

Mitchell J. Nathan
University of Wisconsin-Madison
mnathan@wisc.edu

This study examined how access to Dynamic Geometry Software (DGS) influences undergraduate students' deductive geometric reasoning through embodied cognitive pathways. Structural equation modeling revealed a modest positive effect of DGS access overall, but passive viewing and non-dynamic interactions showed stronger positive associations with reasoning performance than dynamic interactions, which had a weak negative association. The latent embodiment constructs (sensorimotor simulation and imagery formation) were both moderately associated with deductive reasoning, yet neither was positively activated by dynamic interactions. These patterns suggest a more complex account of how physical interaction shapes geometric reasoning in technology-enhanced environments than typically reported in DGS research.

Keywords: Geometry and Spatial Reasoning, Technology, Cognition, Learning Theory

Deductive proof (i.e., reasoning that is general, logical, and operative; Harel & Sowder, 2007) is a central goal of geometry instruction and a persistent challenge for students at all levels (Dreyfus, 1999). Dynamic Geometry Software (DGS) has been widely adopted to support geometry learning, and meta-analyses report positive effects on mathematics outcomes (Chan & Leung, 2014; He et al., 2025). Yet two important gaps remain. First, most DGS studies treat the technology as a uniform intervention and focus on procedural achievement rather than deductive reasoning specifically, leaving open whether and how DGS access supports proof construction. Second, while research in mathematics education increasingly implicates the body in geometric reasoning—suggesting that embodied cognitive processes may mediate the relationship between physical interaction and mathematical thinking—this pathway has not been systematically modeled, and no study has examined how different types of DGS interaction relate to it.

The present study addresses both gaps. Using structural equation modeling, we examine how DGS access and interaction type relate to undergraduate students' deductive geometric reasoning through two theorized embodied cognitive mechanisms: imagery formation and sensorimotor simulation.

Theoretical Framework

Grounded and Embodied Mathematical Cognition

Grounded and embodied cognition holds that mathematical reasoning is rooted in perceptual and motor experiences, not purely symbolic manipulation (Barsalou, 2008; Nathan & Walkington, 2017). In geometry, students who produce dynamic representational gestures depicting transformations of geometric objects are more likely to construct valid, generalizable proofs (Nathan et al., 2021; Walkington et al., 2022), while pointing gestures help ground

reasoning in the diagrammatic environment (Alibali & Nathan, 2012). These findings suggest that physical action and geometric reasoning are deeply intertwined.

Two cognitive constructs are central to this relationship. *Imagery formation* refers to the construction of task-relevant mental images of geometric objects (i.e., what a student mentally "sees" while reasoning). *Sensorimotor simulation* refers to the activation of motor processes associated with transforming or manipulating those objects, even without overt movement. Both constructs figure centrally in Hostetter and Alibali's (2008) Gestures as Simulated Action (GSA) framework. GSA proposes that as people think, they mentally simulate actions and perceptual states; when the resulting motor activation surpasses an individual's gesture threshold, it is externalized as gestures. Critically, GSA predicts a sequential relationship: imagery formation precedes and activates sensorimotor simulation, which may then be expressed as gesture. Simulation strength varies with imagery type (i.e., motor imagery activates the motor system more strongly than purely visual imagery), and both constructs are theorized to support the spatial-relational thinking underlying deductive proof (Hostetter & Alibali, 2008, 2019).

The theory of action-cognition transduction (ACT; Nathan, 2017) complements GSA by positing that the relationship between thinking and action is bidirectional: deliberate physical action can induce cognitive states through a reciprocal coupling of motor and cognitive systems, not merely reflect them. In geometry, this means that physically engaging with diagrams may directly activate imagery formation and sensorimotor simulation, thereby strengthening conceptual reasoning.

Dynamic Geometry Software

DGS allows students to construct and dynamically modify geometric figures, interacting with invariant mathematical properties unavailable in static diagrams (Hollebrands, 2007). By enforcing mathematical constraints and enabling epistemic actions (Kirsh & Maglio, 1994), DGS makes problem-solving more reliable. Touch-based implementations further afford haptic interactions that may directly engage the embodied processes underlying geometric reasoning (Sinclair & de Freitas, 2014). From an ACT and GSA perspective, dynamic manipulation of diagrams may intensify motor imagery, strengthen sensorimotor simulation, and thereby support proof construction. Meta-analyses consistently report large positive effects of DGS on mathematics outcomes ($g = 0.82 – 1.02$; Chan & Leung, 2014; He et al., 2025; Y. Zhang et al., 2025), with qualitative work confirming that DGS supports novel forms of embodied interaction (Pittalis & Drijvers, 2023). However, these studies treat DGS as a uniform intervention and rarely examine deductive reasoning or how different interaction types engage embodied cognitive processes.

Current Study

Drawing on GSA and ACT, we developed a cognitive model of deductive geometry reasoning with and without DGS access (Figure 1), representing three latent constructs: *imagery formation* (manifested by intuition and insight), *sensorimotor simulation* (manifested by dynamic, non-dynamic, and pointing gestures), and *deductive geometric reasoning* (manifested by general, logical, and operative reasoning; Harel & Sowder, 2007). We further distinguish three mutually exclusive DGS interaction types: *dynamic interaction* (transforming, scaling, or moving diagrams), *non-dynamic interaction* (static contact without manipulation), and *passive viewing* (observation without physical contact), representing a gradient from most to least motorically demanding.

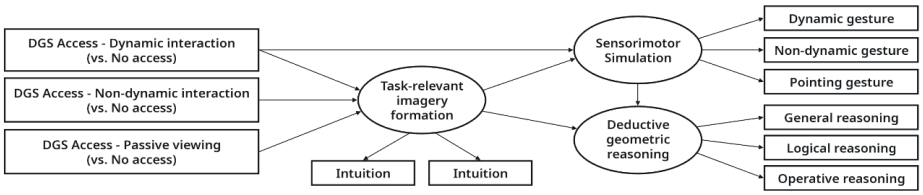

Figure 1: Hypothesized Relationship Between Constructs

With this model, we focus on how the three types of DGS interaction relate to deductive geometric reasoning. A complementary question concerning the overall effect of DGS access on deductive geometric reasoning is examined in a separate report and is not addressed in this manuscript. Here, we ask: *How do associations between DGS interaction type and deductive geometric reasoning differ across the three interaction types*? We hypothesize that the associations between interaction type and deductive reasoning will differ significantly, with dynamic interaction expected to show the strongest positive association due to its combination of visual and motor engagement.

Methods

Participants

Undergraduates (n = 158; mean age = 20.19; 92 female, 65 male, 4 non-binary) were recruited from a large Midwestern university. Ninety-five students identified as White/Non-Hispanic, 52 as Asian, and 11 as Other Race/Ethnicity. 107 students had completed college-level calculus or higher.

Study Design

Experimental design overview. We conducted a randomized within-subjects repeated-measures experiment in which students provided geometric reasoning for eight conjectures. Each student completed half the conjectures with DGS access and half without (Figure 2), with the presentation order of conjectures counterbalanced using a Latin Square design.

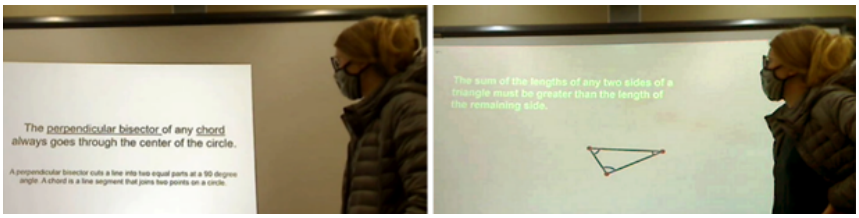

Figure 2: Proving Conjectures Without DGS Access (Left) and With DGS Access (Right)

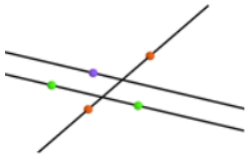
Procedure and materials. Upon enrollment, students filled out online surveys. Researchers used the *Spatial Reasoning Instrument* (Ramful et al., 2017) to measure students' spatial ability, the *Spatial Anxiety Survey* (Lyons et al., 2018) for spatial anxiety, the *Diagnostic Geometry Assessment* (Masters, 2010) for geometry knowledge, and the *Situational Interest Survey* for academic domains (Linnenbrink-Garcia et al., 2010) for attitudes toward geometry.

Students worked in a laboratory space with a projected display and an interactive whiteboard. They proved or disproved eight geometry conjectures, each concerning objects and properties commonly featured in high school geometry curricula. Corresponding GeoGebra 3D Calculator simulations were developed for each conjecture and rendered on a large, touch-enabled

Promethean digital whiteboard, allowing direct manual manipulation (Figure 3). All conjectures were categorically true in Euclidean geometry. Students initially received only conjecture texts and vocabulary definitions for the first four conjectures (Figure 2 Left). After completing these, they watched a 5-minute tutorial on manipulating GeoGebra simulations. For the remaining four conjectures, simulations were presented alongside conjecture texts (Figure 2 Right). The facilitating researcher instructed students to use simulations at their discretion, neither encouraging nor discouraging them.



Conjecture: *If two parallel lines are cut by a third line, the pairs of corresponding angles are congruent.*		**Insight:** e.g., "The transversal cuts both parallel lines at the same angle. If you know one of the angles is 30 degrees, you use theorems to show that every angle has to be either 30 degrees or 150 degrees."

Figure 3: Example of Conjecture, GeoGebra Simulation, and Proof with Insight

Data Collection and Processing

Students' responses were video recorded, with a single video file created for each student. These video recordings were segmented by conjecture, yielding 1,264 conjecture responses and corresponding video clips. After quality screening, 1,239 responses were deemed eligible. The eligible responses were initially transcribed using Otter.ai and subsequently reviewed by human coders. Transcripts were then qualitatively coded for verbal reasoning and gesture production using MAXQDA 2022.

Variables

DGS access and interaction type indicators. Variable names are capitalized (e.g., "Name") to distinguish them from their corresponding theoretical constructs (e.g., "name"). *DGS Access* served as the response-level indicator for within-subjects treatment assignment, coded as "1" for responses with DGS access and "0" for those without.

Based on qualitative observations during data collection, we identified systematic variation in how students engaged with the DGS simulations. Although interaction type was not part of the original experimental design, these observed patterns prompted a post hoc classification of student interactions into three mutually exclusive categories, each theorized to differ in the degree to which they engage sensorimotor processes relevant to conjecture proof. *Dynamic Interaction* indicated transformative engagement with the simulation (e.g., transforming, scaling, or moving diagrams) believed to most strongly activate sensorimotor processes. *Non-Dynamic Interaction* indicated static physical contact unlikely to stimulate sensorimotor processes to the same degree (e.g., rotating the view or touching the board without manipulating figures). *Passive Viewing* indicated observation of the simulation without any physical contact.

All indicators were binary (0/1), coded once per response regardless of frequency. To ensure mutual exclusivity, we employed a hierarchical coding strategy in two stages. In the first stage, two researchers independently coded each response qualitatively for the presence of any physical interaction with the simulation, distinguishing responses that involved touching the board from those that did not (interrater reliability $\kappa = .92$). In the second stage, responses coded as involving physical interaction were further coded for whether that interaction was dynamic (i.e., whether the student actively transformed or manipulated the geometric figures) or non-dynamic ($\kappa = .92$). Dynamic Interaction superseded Non-Dynamic Interaction when both types of

interactions were found, and Non-Dynamic Interaction superseded Passive Viewing, such that each response received exactly one interaction type code.

Outcome variables. We qualitatively coded each response for five verbal reasoning characteristics and three gesture categories using binary classifications (0/1, absent/present). Unlike DGS access and interaction variables, outcome codes were not mutually exclusive. Raw proportions of outcome variables are shown in Table 1.

Table 1: Raw Proportions of Outcome Variables

		Verbal Reasoning					Gesture Production		
	n	Int.	Ins.	Gen.	Log.	Ope.	Dyn.	N-Dyn.	Point.
No Access	618	.73	.73	.53	.46	.45	.16	.64	.01
DGS Access	621	.79	.81	.57	.52	.55	.16	.44	.35
Dynamic Interaction	182	.77	.80	.50	.42	.45	.15	.39	.39
Non-Dynamic Interaction	200	.75	.76	.60	.54	.56	.22	.46	.26
Passive Viewing	239	.83	.84	.59	.55	.60	.13	.46	.40
Whole sample	1239	.76	.77	.55	.49	.50	.16	.54	.18

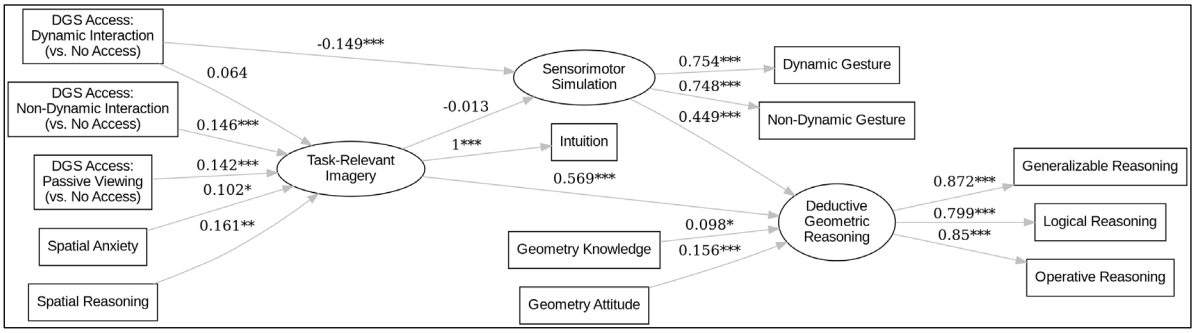
Note. Int. = Intuition, Ins. = Insight, Gen. = General, Log. = Logical, Ope. = Operational, Dyn. = Dynamic, N-Dyn. = Non-Dynamic, Point. = Pointing

Verbal reasoning characteristics included *Intuition* (immediate correct judgments without extended deliberation; $\kappa = .96$), *Insight* (explicit retrieval and correct application of mathematical properties; $\kappa = .86$; Z. Zhang et al., 2016), and three deductive reasoning attributes following Harel and Sowder's (2007) taxonomy: *General* reasoning (addressing entire object classes rather than specific instances; $\kappa = .87$), *Logical* reasoning (coherent inferential chains; $\kappa = .84$), and *Operative* reasoning (goal-oriented, mathematically purposeful thinking; $\kappa = .86$). Gestures were categorized into three types. First, Pointing Gestures (referring to simulation displays or imagined objects; $\kappa = .87$) and two types of representational gestures were classified as Dynamic Gestures (hand movements showing object transformations across different states; $\kappa = .88$) and Non-Dynamic Gestures (representing static objects or properties; $\kappa = .85$; Garcia & Infante, 2012).

Statistical Modeling

Unit of analysis. The unit of analysis was the response to a given conjecture ($n = 1{,}239$). Although responses were nested within students, preliminary clustering analyses using design effect coefficients and intraclass correlations supported single-level analyses with robust corrections (Muthén & Satorra, 1995; Stapleton et al., 2016), as our theoretical interest lies at the response level, where DGS access and interaction are operationalized.

Modeling framework. We employed structural equation modeling using a multiple-indicator-multiple-cause (MIMIC) approach. Unlike ANOVA or generalized linear models, which treat outcome variables separately, the MIMIC framework simultaneously examines treatment effects on multiple correlated indicators while representing their shared cognitive architecture through latent constructs (Hancock, 2003). This approach also enabled modeling of direct DGS effects and mediation among latent constructs (Figure 1), consistent with our theoretical model, and allowed incorporation of baseline covariates—spatial ability, geometry knowledge, and demographic characteristics—for more precise effect estimates. Following Mueller and Hancock (2019), we first established an acceptable measurement model before testing structural relationships.



Technical details. Analyses were conducted in R using the {lavaan} package (Rosseel, 2012) with the Weighted Least Squares Mean- and Variance-adjusted (WLSMV) estimator, appropriate for binary outcomes. Latent variable variances were constrained to unity for model identification. All structural paths are reported as standardized coefficients (β), with effect size receiving primary interpretive emphasis alongside continuous p-values.

Results

Measurement Model and Latent Variables Evaluation

The three latent constructs (i.e., imagery formation, sensorimotor simulation, and deductive geometric reasoning) were specified in the measurement model. Insight and Pointing Gesture were excluded from the final measurement model due to severe multicollinearity issues. As a result, Imagery Formation used a single indicator (Intuition) with its loading fixed to 1.00. The final measurement model showed adequate fit across multiple indices: scaled CFI = .991, scaled TLI = .980, scaled RMSEA = .049 (90% CI: .031–.069), and scaled SRMR = .037.

The measurement model demonstrated adequate convergent validity and reliability. Sensorimotor Simulation was measured through Dynamic Gesture (λ = .78) and Non-Dynamic Gesture (λ = .68), with Deductive Geometric Reasoning measured through General (λ = .88), Logical (λ = .80), and Operative (λ = .84) reasoning attributes, all showing strong loadings (p < .001 for all three). Reliability assessment using Hancock and Mueller's (2001) Coefficient H yielded H = .704 for Sensorimotor Simulation and H = .885 for Deductive Geometric Reasoning, both exceeding the .70 threshold for factor replicability. The Imagery Formation construct was represented by a single indicator (H = 1.00) and was thus evaluated on theoretical grounds. Measurement invariance across conditions was established per Cheung & Rensvold (2002).

Note. • for p < .1,* for p <.05, ** for p <.01, *** for p < 0.001.

Figure 4: Fitted Structural Model with Path Coefficients

Structural Model and Direct Path Coefficients

The structural model (Figure 4) showed adequate fit across multiple indices: scaled CFI = .912, scaled TLI = .968, scaled RMSEA = .057 (90% CI: .050–.065), and scaled SRMR = .039. After excluding Insight and Pointing Gesture due to collinearity issues, modification indices suggested no further meaningful sources of misfit. Path coefficients revealed varied associations between DGS interaction types and cognitive processes. Dynamic Interaction had a weak positive association with Imagery Formation (β = .064, p = .097) but a stronger negative association with Sensorimotor Simulation (β = –.149, p < .001). Non-Dynamic Interaction (β = .146, p = .001) and Passive Viewing (β = .142, p = .001) both showed clearer positive associations with Imagery Formation. The path from Imagery Formation to Sensorimotor

Simulation was essentially zero ($\beta = -.013$, $p = .816$), providing little evidence of association. In contrast, both Imagery Formation ($\beta = .569$, $p < .001$) and Sensorimotor Simulation ($\beta = .449$, $p < .001$) showed strong positive associations with Deductive Geometric Reasoning.

Indirect Effects of DGS Interaction Type on Deductive Geometric Reasoning

We adopt correlational language given that interaction type categories were not randomly assigned. The associations between interaction types and Deductive Geometric Reasoning varied considerably. Dynamic Interaction showed a weak, negative, and statistically insignificant association with Deductive Geometric Reasoning ($\beta = -.031$, $p = .228$). In contrast, both Non-Dynamic Interaction ($\beta = .082$, $p = .001$) and Passive Viewing ($\beta = .080$, $p = .001$) demonstrated positive associations with deductive reasoning.

The omnibus Wald statistic for testing parameter equality constraints was $W(2) = 14.36$ ($p = .001$), suggesting the magnitude of the associations differs across the interaction types. Pairwise comparisons revealed that Dynamic Interaction's association with Deductive Geometric Reasoning was smaller than both Non-Dynamic ($\Delta = -.113$, $p < .001$) and Passive Viewing ($\Delta = -.111$, $p < .001$), while Non-Dynamic Interaction and Passive Viewing's associations showed little difference ($\Delta = .002$, p = .942). These findings appear consistent with part of our hypothesis that different types of DGS interactions may be differentially associated with the deductive geometric reasoning outcomes. However, the direction of these associations contradicts our hypothesis: rather than showing the strongest positive association with deductive reasoning, dynamic interaction showed a weak negative association, while the less motorically demanding interaction types showed stronger positive associations.

Discussion

Findings

The findings present a nuanced picture of how the way students engage with DGS shapes deductive geometric reasoning through embodied cognitive pathways. Contrary to our hypothesis that more active manipulation would most strongly support reasoning, the three interaction types were associated with deductive geometric reasoning in markedly different ways.

Specifically, passive viewing ($\beta = .080$, $p = .001$) and non-dynamic interaction ($\beta = .082$, $p = .001$) showed stronger positive associations with deductive reasoning than dynamic interaction, which showed a weak negative association ($\beta = -.031$, $p = .228$), with differences across interaction types being statistically meaningful ($W(2) = 14.36$, $p = .001$). Rather than more interaction being uniformly better, students who observed or lightly engaged with the simulation appeared to reason more successfully than those who actively manipulated it.

Theoretical Implications

Several explanations may account for this pattern. First, a self-selection mechanism is plausible: students who found a conjecture familiar may have felt little need to manipulate the simulation, while those who struggled engaged more intensively, which is consistent with Walkington et al. (2024). The negative association with dynamic interaction may thus reflect conjecture difficulty or prior knowledge rather than a direct effect of manipulation. Second, Physically Distributed Learning theory (Martin, 2009) suggests that dynamic interaction may have over-structured the environment, reducing the interpretive cognitive work that supports proof construction. Non-dynamic interaction and passive viewing may have required students to mentally simulate geometric relationships themselves, which is a productive struggle that proof-oriented reasoning demands. Cognitive load concerns may have further compounded this effect (Reis et al., 2012).

The negligible path from imagery formation to sensorimotor simulation ($\beta = -.013$, $p = .816$) raises further questions about how embodied processes operate in technology-enhanced settings. Rather than functioning as sequentially linked processes as GSA predicts, the two constructs appeared largely independent. DGS may have shifted students' imagery toward visual rather than motor encoding (i.e., externalizing the geometric transformations students would otherwise mentally enact) thereby weakening the imagery-to-simulation pathway. This suggests the relationship between imagery and sensorimotor simulation may be more context-dependent than GSA originally theorized.

This null path may also reflect how sensorimotor simulation was measured. Because the construct was operationalized through observed gesture, it inherits the threshold dynamics that GSA itself describes. Dynamic gestures, which depict transformations across states, had a high standardized threshold ($\tau = 1.03$) and appeared in only 16% of responses, whereas non-dynamic gestures had a much lower threshold ($\tau = -.36$) and appeared in 54%. If imagery formation activated motor processes only modestly, that activation may have been sufficient to produce low-threshold non-dynamic gestures but insufficient to cross the higher threshold for dynamic gestures, obscuring an imagery-to-simulation link that gesture-based measures may be unable to detect, which is a measurement dependency that Hostetter and Alibali (2019) themselves identified as a limitation in need of independent measures of simulation.

Practical Implications

These findings carry practical implications for DGS-based geometry instruction. Educators should not assume greater interactivity uniformly benefits proof-oriented reasoning; structured observation may support deductive reasoning as effectively as open-ended exploration. Instructors should also select conjectures for which dynamic manipulation genuinely reveals properties unavailable in a static diagram. More broadly, the modest overall effect reinforces the idea that how students interact with DGS and how instructors structure those interactions matters more than access alone.

Future Inquiry

The most consequential limitation is that the interaction type was classified post-hoc from naturally occurring behavior. Because students self-selected into interaction types, causal claims cannot be made. Future studies randomly assigning students to specific interaction protocols would allow stronger conclusions about whether different forms of physical engagement causally influence deductive reasoning. Conjecture-specific analyses also represent a promising direction. Whether dynamic interaction supports reasoning may depend on whether the conjecture's key property is genuinely revealed through manipulation or equally accessible through observation. Future work incorporating eye-tracking, think-aloud protocols, or fine-grained gesture analysis could further illuminate the moment-to-moment cognitive processes linking DGS interaction to proof construction.

This theoretical report examines children's emerging conceptions of geometric shape, especially in light of Piaget and Inhelder's (1967/1948) topological primacy thesis and Klein's Erlangen program. We focus on aspects of shapes that children find most salient when representing them with drawings. Within our Erlangen framing, the topological primacy thesis aligns with a progression of invariances under transformation, requiring increasing coordination of actions. Pilot study results from 21 four- and five-year-olds indicate support for the thesis when framed this way. An interesting exception was children's attention to the preservation of perpendicularity.

Keywords: Cognition, Early Childhood Education, Geometry and Spatial Reasoning, Learning Theory

Based on their extensive studies with children, Piaget and Inhelder (1967/1948) characterized the development of geometric intuition as a progression in children's constructions, from topological properties (e.g., enclosure), to projective properties (e.g., linearity), to Euclidean properties (e.g., length and angle measure). Although several subsequent studies have replicated Piaget and Inhelder's findings, affirming the progression, some researchers have criticized their interpretations of findings and their theoretical underpinning—often referred to as "the topological primacy thesis" (Darke, 1982).

A main concern among critics is that Piaget and Inhelder mischaracterized some properties of shapes as topological when they would be mathematically categorized as projective or Euclidean. For example, Piaget and Inhelder (1967/1948) stated, "our experiments have shown how important such actions are in the mental construction of shapes, based on elementary topological relations such as proximity, order, and enclosure" (p. 449). However, formally speaking, the *order* of points is a projective property that is not generally preserved under topological transformation, and *proximity* implies a metric (measurement), which is a Euclidean property. To resolve these issues, we turn to the hierarchy of geometries established by Klein's (1893) Erlangen program.

The Erlangen program aligns with Piaget and Inhelder's broader epistemology of mathematics in that it foregrounds *actions* as the basis for mathematical development. In fact, Piaget (1950) cited Klein's work broadly, noting the alignment but without relying on the detailed characterizations the program might have provided him. Klein studied mathematics from the perspective of invariants: What remains unchanged under a transformation? For example, if we perform an isometry (e.g., a spatial rotation) on a Euclidean shape, such as a square, it maintains that shape. So, we can characterize Euclidean shapes and properties as those that remain invariant under isometry (e.g., angle measure and side length). In foregrounding actions over properties, Klein characterized Euclidean geometry by the group of transformations (isometries) that preserve those properties, rather than by the properties themselves.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

With Piaget and Inhelder's research in mind, we designed a study to investigate preschoolers' emerging conceptions of perpendicularity. As part of that study, we assessed children's emerging conceptions of geometric shape, partially replicating a study by Piaget and Inhelder and using Klein's Erlangen program to address some of the prior critiques of this work. Specifically, children were asked to draw copies of pictures that depicted a circle or pairs of line segments (parallel or intersecting). In analyzing children's drawings, we asked ourselves, "Which geometric aspects of the shape does the child consider salient in producing their drawing?"

We designed a rubric, beginning from Piaget and Inhelder's characterizations of various geometric properties (e.g., enclosure and angle preservation) but modified to align with Klein's hierarchy of geometries. Our goal was to refine Piaget and Inhelder's characterizations by explicitly identifying various kinds of invariants and the corresponding transformations, or mental actions, that preserve them. Thus, we introduce a refined theory of children's development of geometric intuition, while partially replicating Piaget and Inhelder's work to elucidate the theory and to begin answering the following question: Does children's development of geometric intuition progress according to greater invariance under transformation? As such, this paper serves as a theoretical report that fits within PME-NA's Geometry and Measurement Strand: "teaching and learning of geometry, measurement, and spatial reasoning."

Theoretical Framework

The Topological Primacy Thesis

In *The Child's Conception of Space*, Piaget and Inhelder (1967/1948) report on their extensive studies of children's development of geometric intuition. The central thesis of this work—"intuition of space is not a reading or apprehension of properties of objects, but from the very beginning, an action performed on them" (p. 449)—extends from Piaget's epistemology of mathematics. Namely, Piaget (1950) framed mathematics as a product of human activity that progresses through increasingly complex coordinations of mental actions. Applying this epistemology to space and geometry, Piaget and Inhelder describe the theoretical progression as follows: "From the rudimentary sensorimotor activity right up to abstract operations, the development of geometric intuition is that of an activity, in its fullest sense" (p. 449).

The principal finding from this work was the identification of stages in children's development of geometric intuition. Elementary intuition begins at Stage 1 (~four years of age), wherein children evoke thought by reproducing sensorimotor actions in imagination. In one of the related studies, Piaget and Inhelder asked children at various stages/ages to draw copies of shapes shown to them. Analyzing children's drawings (and accounting for variance in fine motor skills), the researchers found that children at Stage 1 progressively attended to topological aspects of the shapes (e.g., distinguishing closed curves, such as circles, from open curves) but did not attend to projective or Euclidean aspects of those shapes (e.g., straight lines or angle measures). For instance, the top row of Figure 1 shows, from left to right, Stage 1 drawings of a circle, a triangle, and a square. Note that all three drawings appear as simple closed curves (preserving enclosure), with four tick marks tacked onto the square to mark its four sides or vertices but with no angles or straight lines included in the closed curve.

Progressive attention to topological aspects culminates at Substage 1B (between three-and-a-half and four years of age) when "one can begin to speak of real drawings, though curiously enough it is only topological relationships which are indicated with any degree of accuracy, Euclidean relationships being completely ignored" (Piaget & Inhelder, 1967/1948, p. 55). The second row of Figure 1 illustrates the progression and its culmination with drawings of a circle from children at the beginning of Stage 1 (Stage 1A, left), Stage 1B (middle), and Stage 2 (right).

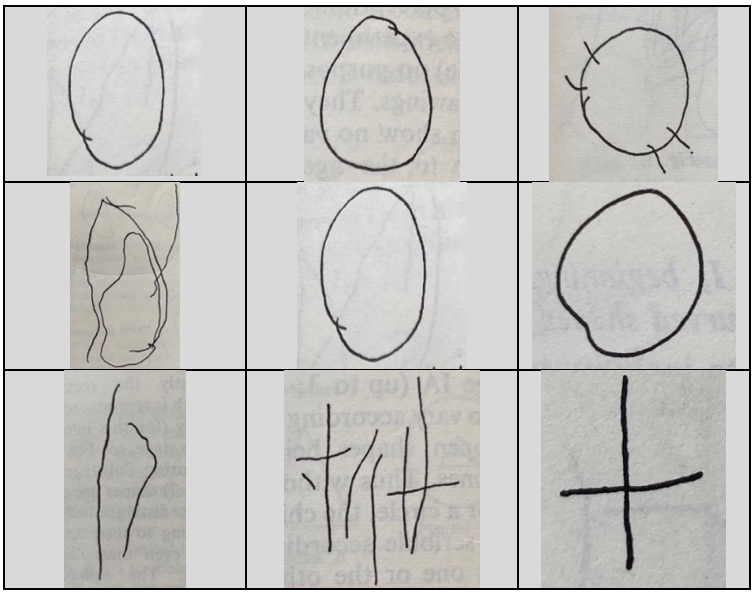

Figure 1: Shape Drawings from Piaget and Inhelder (1967/1948)

Starting at Stage 2, (~four years of age), children make progressively finer distinctions in their drawings, beginning with projective properties (e.g., straight vs. curved lines) and continuing into Euclidean ones (preserving angle measures and side lengths). The third row of Figure 1 illustrates this emergence of attention to projective and Euclidean aspects of shape, with drawings of a cross (+) from children at Stage 1A (left), Stage 1B (middle), and Stage 2 (right). Note the Stage 1A drawing does not preserve the topological property of intersection, but the Stage 1B drawing does, with some effort (repeated attempts). The Stage 2 drawing additionally includes consistently straight lines, four right angles, and approximately equal segment lengths.

Critiques of the Thesis

Several studies have replicated this work, generally affirming its findings (e.g., Kato, 1986; Pinard & Laurendeau, 1966). However, other researchers have been more critical of the central thesis of the work: the topological primacy thesis (e.g., Clements & Battista, 1992; Kapadia, 1974; Martin, 1976b). As summarized by Darke (1992), these critiques include two broad concerns: (1) the characterization of topological properties, as interpreted by the researchers; and (2) the instructional implications of this work, as interpreted by educators.

Regarding the first concern, some critiques misrepresent Piaget and Inhelder's work. For example, Kapadia (1974) critiqued the researchers for misuse of terms like proximity and order, only to conclude, "we believe, contrary to Piaget and Inhelder, that continuity is one of the earliest aspects of space representation" (p. 422). Although Piaget and Inhelder (1967/1948) might have used terms like proximity and order unconventionally, they explicitly related each topological term to continuity, which lies at the heart of the topological primacy thesis.

Other critiques, such as those offered by Martin (1976a; 1976b), are more constructive. Martin (1976b) also raised concerns about language: "Piaget's use of the term separation does not correspond to mathematical usage" (p. 16). However, he also seemed to appreciate Piaget and Inhelder's intent and suggested: "Perhaps the emphasis should be placed on the child's ability to order, organize, and coordinate his actions, not on trying to chronologically order spatial representation according to topology, Euclidean geometry, or projective geometry" (p.

15). This suggestion certainly fits within Piaget's broader epistemology of mathematics, but without the danger of imposing formal mathematics onto children's mathematical development.

In a second article, Martin (1976a) shared results of a study conducted to test the topological primacy thesis. That study tasked children with drawing copies of different shapes, including some of those used by Piaget and Inhelder: a square with one diagonal, and a circle inscribed in a triangle. Each of these shapes displayed both topological properties (e.g., connectedness and enclosure) and projective properties (e.g., straight vs. curved lines). Drawings were classified, first by determining whether they were homeomorphic to the given shape, meaning they shared *all* topological properties. Then, among the homeomorphic and non-homeomorphic copies, drawings were classified according to the degree to which they satisfied projective properties. Martin found that, among the 30 four-year-olds in the study, 40% of their drawings were homeomorphic to the given shape, and 7% of their drawings preserved all projective properties (whether or not they were homeomorphic). However, because most (67%) non-homeomorphic drawings preserved *some* projective properties, Martin determined that "none [of the data] indicate that the four-year-old's representational space is predominantly topological" (p. 37).

Regarding the second concern, Martin noted, "although making implications for mathematics education is not a primary objective of Piaget, mathematics educators do make inferences from his research" (Martin, 1976b, p. 24). One unintended implication of Piaget and Inhelder's work was the introduction of formal topological properties in elementary school. The more appropriate implication would be a focus on children's mental actions and their coordination as children construct mathematics through their own activity. For instance, drawing upon a case study with a seven-year-old student, Greenstein (2014) suggested teachers could "build on their students' emergent geometric reasoning and make sense of transformation-based ideas (e.g., property, equivalence, invariance)," whether transformations were topological or Euclidean (p. 93).

Similarly, working with 18 kindergarteners (five to six years old), Davis and Hyun (2005) found that they could support children's development of geometric intuition through interactive investigations and reflections on those activities. In line with Piaget and Inhelder's topological primacy thesis, at the start of the study, children's drawings exhibited more topological properties than projective or Euclidean properties, by a 3:1 ratio. However, toward the end of the school year, the ratio had reversed, 1:4. This result aligns with prior findings, indicating that children do come to school with many topological concepts and that instruction focused on Euclidean concepts can begin there (Schipper, 1983). Although these findings at least partially align with the topological primacy thesis, Davis and Hyun (2005) concurred with an alternative hypothesis advanced by Clements and Battista (1992): "It may be that ideas of all types develop over time, becoming increasingly integrated and synthesized. These ideas are originally intuitions, grounded in action …" (pp. 425–426), which also fits Martin's (1976b) suggestion.

An Erlangen Solution

As noted, part of the problem with Piaget and Inhelder's (1967/1948) topological primacy thesis owes to their use of terms. In the case of "order," the researchers seemed to have in mind the intermediate value theorem (curves passing through intermediate points), which relates to continuity and, therefore, topology. In the case of proximity, the researchers did not refer to a metric but a qualitative aspect of perception: "The most elementary spatial relationship which can be grasped by perception would seem to be that of proximity, corresponding to the simplest type of perceptual structurization, namely the nearby-ness of elements belonging to the same perceptual field" (p. 6). They contrast proximity with separation, wherein children begin to distinguish two objects that could be touching (e.g., a chair leaning against a wall) as two

separate objects. They relate these terms—proximity and separation—to continuity via Weber's Law "in terms of the increasing fineness of the thresholds of sensitivity" (p. 8).

To address the larger problem of topological primacy—concerning whether children's development of geometric intuition follows a progression from topological, to projective, to Euclidean—we rely on Klein's Erlangen program. The program classifies geometries based on (groups of) geometric transformations and the properties that they preserve (invariants). This focus on transformations aligns with Piaget's (1950) epistemology of mathematics as a coordination of mental actions. Note that this epistemology also aligns with perspectives offered by critics of the topological primacy thesis (Clements & Battista, 1976; Martin, 1976b). What remains unclear is whether the progression from topological, to projective, and Euclidean transformations fits a progression of increasingly complex coordinations of actions; and the Erlangen program offers clarification.

Essentially, the Erlangen program answers the question of what it means for two geometric shapes to be the same, by specifying the actions that transform one shape into another. These mental actions, or transformations, allow some properties to change while leaving others—the properties that define sameness—invariant. Topology has the broadest group of transformations and, therefore, the narrowest set of invariant properties. Two geometric shapes are considered topologically the same (homeomorphic) if each can be transformed onto the other by a bicontinuous transformation (a bijective continuous transformation with a continuous inverse). Importantly, bicontinuous transformations include every projective transformation (projections) and every Euclidean transformation (isometries), but they also include more general transformations that require little coordination. For instance, shapes could be stretched in different directions without any consideration for whether their side lengths or angles remain the same, or even whether the sides remain straight. This is why we might consider bicontinuous (topological) transformations to be primitive, even though the formal definition of continuity appears so late in history and curricula.

Projective transformations form a subgroup of topological transformations: Every projective transformation is bicontinuous, so it preserves all topological properties of a shape. Additionally, projective transformations preserve linearity and order, and preserving these additional properties requires coordination of actions—there is a point of reference from which to produce lines of projection that pass through two shapes that are projectively the same. Affine transformations additionally preserve parallel lines, and similarity transformations (transformations that preserve geometrically similar shapes) additionally preserve angles, requiring further and further coordination.

Similarity transformations consist of isometries and dilations, so Euclidean transformations (isometries) form a subgroup of similarity transformations. Note that isometries are rigid transformations, and so we would consider two shapes to be the same if one can be rigidly transformed onto the other. This is the kind of sameness that Euclid took for granted: "Things fitting on one another are equal to one another" (Fried, 2009, p. 3). However, we can further restrict the group of transformations by removing reflections and rotations, leaving only translations ("the group of displacements;" Piaget & Inhelder, 1967/1948).

By focusing on nested subgroups of transformations, requiring greater coordination to preserve more invariance, the Erlangen program reconciles the topological primacy thesis with alternate hypotheses suggested by Matin (1976b) and by Clements and Battista (1992). Specifically, within the Erlangen program, we can identify increasingly complex coordinations of actions, and an increasing synthesis and integration of ideas that are grounded in action.

Methods: Elucidating Theory with Empirical Examples

Although we present this work as theoretical, we include preliminary results from a pilot study to elucidate the theory. Data come from a larger study on children's emerging conceptions of perpendicularity. The pilot sample included 21 preschoolers (M_{age} = 4.56 years, SD = 0.35; 13 boys, 8 girls), who participated in one-on-one interviews with a researcher. Among other tasks, the pilot study included five drawing tasks like those used by Piaget and Inhelder (1967/1948). Children were introduced to the activity by the researcher, with the researcher demonstrating by copying the circle (Task 0). Then, each child was shown each of the shapes in the top row of Figure 2, one by one, and was asked, "Can you draw this?" when given a blank paper and crayon. Samples of children's drawings are shown in the bottom row of Figure 2.

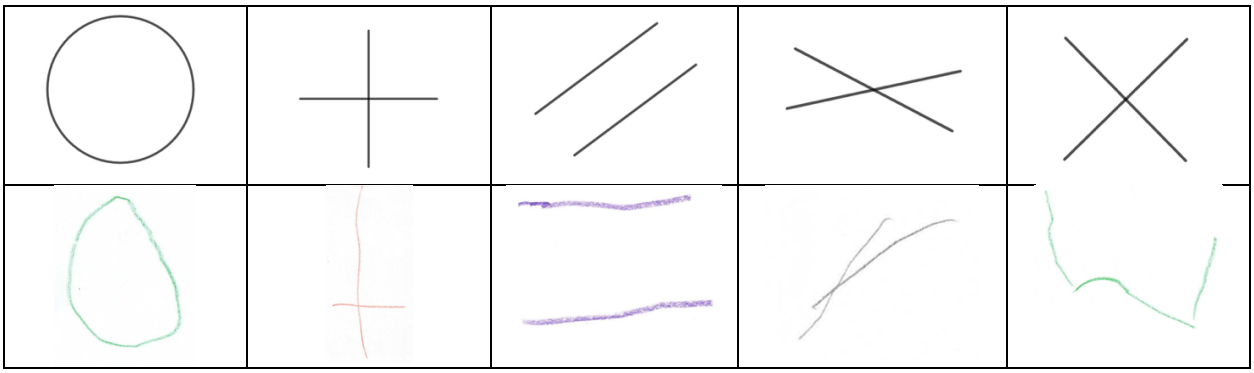

Figure 2: Children's Shape Drawings (T0 to T4)

Drawings were analyzed by a pair of researchers using the rubric described here. For each task, each rater evaluated the following: Does the drawing preserve (1) topological aspects of the shape (enclosure, connectedness, and separations/intersections)? Does the drawing preserve (2) projective (linearity) and (3) affine aspects of the shape (parallelism)? Geometric aspects were subdivided into three categories aligning with increasing degrees of sameness: (4) similarity (angle and proportional lengths), (5) isometry (absolute distances and absolute lengths), and (6) sameness in orientation, which accounts for reflection and rotation. Not every aspect applied to every task (e.g., preservation of parallelism only applied to Task 2). Once the two raters completed scoring for all drawings, the research team met to reconcile discrepancies.

Results: Interpretations of Examples Using Theory

Out of the 861 assessments of various aspects of children's drawings, the two raters achieved 83.86% agreement. Out of their 139 disagreements, 53 (38%) concerned judgements of linearity. The two raters met with the three other members of the research team to reconcile disagreements. In some cases, discrepancies could be resolved using objective measures, applied by a third researcher. For example, we allowed for errors of up to 20%, in either direction, for children's drawings of lengths and angles. In other cases, such as linearity, judgments were more subjective, and the researchers had to determine from children's imperfect drawings whether they were attending to that aspect of the shape. Reconciled scores are presented in Table 1, as ratios of drawings that preserved each aspect of the shape for each task (T0–T4). Note that some of these ratios come from fewer than 21 responses because for some drawings, preservation could not be determined. Most (six out of eight) of these cases concerned the orientation of the shape, as some drawings had no discernable orientation (e.g., the drawing for T4, in Figure 2).

Table 1: Ratios of Drawings Indicating Salience of Properties for Each Shape

Group	Invariant Property	T0	T1	T2	T3	T4
Homeomorphism	Enclosure	16/21	20/21	21/21	18/21	21/21
Homeomorphism	Connectedness		19/21	20/21	18/21	20/21
Homeomorphism	Separation/Intersection		19/21	21/21	17/21	19/21
Projection	Linearity	13/21	13/21	11/21	6/21	7/21
Affine	Parallelism			12/21		
Similarity	Proportional Length	4/21	5/21	12/21	4/21	6/21
Similarity	Angle Measure		**20/21**		1/21	**11/21**
Isometry	Absolute Length		2/21	3/21	0/21	3/21
Isometry	Absolute Distance	1/21	1/20	3/21	0/21	1/20
Displacement	Orientation		**20/20**	**5/21**	**1/18**	**8/19**

Results presented in Table 1 follow the pattern predicted by Piaget and Inhelder's topological primacy thesis. Specifically, topological properties (enclosure, connectedness, and separation/intersection) of each shape are largely preserved; then we see a substantial drop in the preservation of projective properties (linearity) across all five shapes; and another substantial drop, across all five shapes, for Euclidean properties (absolute length and distance). As Piaget and Inhelder (1967/1948) noted, this pattern in children's development fits the reverse order of historical mathematical development, which proceeded from Euclidean geometry, to projective geometry, to topology. This pattern also fits the order of geometries as classified by the Erlangen program, but that program includes additional geometries whose order is determined by the groups of transformations that leave their shapes invariant: affine transformations, which preserve parallelism (as well as linearity); similarity transformations, which preserve angles and proportional lengths; and displacements, which preserve the (angular) orientation of shapes.

When we include these additional groups and their associated invariant properties, the pattern generally holds but is not as clean. First, in the case of Task 2, we do not see a drop off in children's preservation of parallelism relative to their preservation of linearity. Second, although we generally see a substantial drop from projective (and affine) properties to similarity properties—and again to properties preserved by isometry—there are two prominent exceptions. These exceptions appear in bold in the angle measure row of Table 1, for Tasks 1 and 4, which involve shapes with right angles. It appears that children preserve right angles far better than other angles (compare to Task 3), particularly when they are oriented orthogonally, as in Task 1. Third, children reliably preserved the orientation of those shapes; and generally, they preserved orientation as well or better than they preserved absolute lengths and distances.

Discussion

The Erlangen program suggests an inverse relationship between geometric invariants and the groups of transformations that leave those properties invariant (Klein, 1893). Topological invariants are restricted to properties related to continuity (e.g., enclosure), so the group of topological transformations is large—all bicontinuous transformations—and the number of invariants is small. In contrast, Euclidean invariants are many (including angle and length), so the group of Euclidean transformations (isometries) is restricted to rigid transformations of

space. This hierarchy provides a framing to justify Piaget and Inhelder's (1967/1948) topological primacy thesis while reconciling it with Piaget's broader epistemology.

In line with Piaget's epistemology—and some proposed revisions to the topological primacy thesis (Clements & Battista, 1992; Martin, 1976b)—our Erlangen solution suggests that greater invariance requires greater coordination of actions. The group of transformations that define a geometry are like free variables that do not need to be coordinated with one another to determine an invariance within that geometry. In this sense, the proposed theory of development of geometric intuition is similar to the theory of covariation in students' developing understanding of functions and variables: Functions and other equations describe invariant relationships that students learn through increasing coordination of their activity, while leaving free variables free to vary independently (Carlson et al., 2002).

So, the Erlangen program serves to clean up Piaget and Inhelder's (1967/1948) characterizations of various geometric properties, while providing a deeper theoretical basis for their topological primacy thesis (fitting Piaget's broader epistemology of mathematics; Piaget, 1950). However, it also complicates the predicted pattern. In our pilot data, we find strong support for Piaget and Inhelder's thesis but less clear support for the progression implied by the Erlangen program. Clements and Battista's alternative hypothesis explains some of the discrepancy but would not predict the patterns observed in Table 1.

On the one hand, Clements and Battista (1992) note a "bias toward the perpendicular in copying angles" (p. 425), especially when the shape is oriented horizontally or vertically. As illustrated in the sample response to Task 1 in Figure 2, children preserve right angles even when neglecting the proportional lengths of line segments. This bias explains two of the unexpectedly high success rates reported for Task 1 (and, to a lesser degree, one for Task 4) in Table 1. Nearly all of the children's drawings preserved right angles and the orthogonal orientation for Task 1! Furthermore, children preserved right angles in Task 4 far more often than they preserved the non-canonical angles in Task 3. On the other hand, Clements and Battista's framing is not detailed enough to explain relationships between different kinds of transformations/invariants.

Specifically, with the bolded exceptions, and the additional exception of the displacement group, we find a consistent pattern in Table 1 (across all five tasks) corresponding with the transformation groups. These initial results also indicate aspects of shapes most salient to children's drawings, which align with the invariant properties of those groups. For example, a child might straighten a curve in order to preserve enclosure (see sample response to Task 0 in Figure 2), or they might bend a line to create an intersection (see sample response to Task 3). It may be that children can attend to various properties of a shape, especially when teachers bring these properties to their attention, as shown in the classroom study by Davis and Hyun (2005). However, that study also showed an initial disposition toward topological properties among kindergarteners, indicating primacy or greater salience.

In closing, we acknowledge that Piaget and Inhelder's (1967/1948) drawing study results are influenced by the particular shapes/tasks they chose. This limitation is noted by several of their critics (e.g., Clements & Battista, 1992), and it applies to our pilot results as well. However, recall that our tasks were selected for use within a larger project on children's emerging conceptions of perpendicularity. From that perspective, we find it especially interesting that children preserve the perpendicularity of lines so early in their development, especially when the lines take canonical forms (+).

A Mathematics education, rooted in predominantly Eurocentric traditions, often functions as an exclusionary space, hindering the development of robust mathematical identities for many students, particularly Muslim students who face underrepresentation and marginalization. To address this inequity, this conceptual paper proposes the Narrative-Ethnomathematics Framework for Geometry (NEFG) as an interdisciplinary pedagogical model for creating inclusive learning spaces. Drawing on Culturally Relevant Pedagogy, Funds of Knowledge, ethnomathematics, and identity research, the NEFG leverages geometry instruction to counter narratives of exclusion. The framework comprises three interwoven strands: Narratives, Ethnomathematics, and the Mathematical/Disciplinary strand. Together, these strands aim at connecting abstract geometrical concepts to real-world cultural heritage.

Keywords: Elementary School Mathematics, Ethnomathematics, Geometry

Mathematics education remains an exclusionary space that is rooted in predominantly Western and Eurocentric traditions, which "limits many students' opportunities to develop identities as mathematically capable learners and thinkers" (Louie, 2017, p. 489). This culture of exclusion creates inequitable learning spaces and poses a pedagogical challenge (Louie, 2017). Mathematics teachers often struggle to devise meaningful, authentic, and relevant learning opportunities that are respectful, ethical, and inclusive of their students' diverse histories and onto-epistemologies. This challenge is particularly critical with Muslim students in the United States, where the growing anti-Muslim rhetoric (i.e., islamophobia) is compounded by the fact that Muslim students are absent from mathematics research (Salem, 2019). In 2025, the Council of American-Islamic Relations (CAIR) Foundation noted various instances where Muslim students were bullied in schools or faced forms of discrimination and/or misunderstanding across multiple states. Additionally, because the current educational framework often falls short in providing a comprehensive understanding of global perspectives, Muslims' histories, mathematical contributions, and sense-making systems are absent from any representation in the curriculum (Salem & Tillis, 2021). This lack of representation can lead to creating learning spaces that are alienating, thereby reinforcing marginalization and racialized identities.

To address this gap, we draw from research on culturally relevant pedagogy (CRP) (Ladson-Billings, 1995), Funds of knowledge (Moll et al., 1992), ethnomathematics (D'Ambrosio, 1985), and mathematics identity research to leverage geometry instruction to counter narratives of exclusion and difference in mathematics curriculum. Integrating the cultural context of Islamic geometry and picture books (Russo & Russo, 2018) serves as a critical, proactive intervention model to honor students' Funds of knowledge (FoK), improve academic outcomes, and foster empathy (McAndrew et al., 2017). This conceptual paper proposes the Narrative-Ethnomathematics Framework for Geometry (NEFG) as an interdisciplinary pedagogical model

for inclusive learning spaces in mathematics, especially for Muslim students. It uses picture books to link core mathematical concepts in geometry, socio-historical context, and cultural practices of Muslims to create meaningful learning contexts. The ethnomathematics dimension of the NEFG extends prior scholarship that has applied culturally grounded mathematical frameworks with Indigenous student populations, broadening this body of work to consider Muslim students' cultural knowledge systems and mathematical heritages.

We acknowledge the need for greater specificity regarding the mathematical and cultural dimensions of Muslim geometry, moving beyond broad generalizations to avoid framing this cultural tradition as a monolith. Despite their varied cultural and ethnic origins, Muslims share a cohesive belief system grounded in the Qur'an and the Sunnah, where racial and ethnic differences are reconciled through a common meaning-making system that fosters unity and counters external perceptions of differences. The Islamic art and history are rooted in their common meaning systems.

Positionality and Researcher Reflexivity

As interdisciplinary scholars working at the intersection of mathematics education and literacy studies, we recognize that our identities and professional trajectories shape the conceptualization and interpretation of this work.

Wesam's experiences as a first-generation Muslim American scholar and parent inform her attention to belonging, representation, and the emotional dimensions of mathematical learning. Her children's reports of feeling different and disconnected underscored the need for this work. Her research investigates and seeks to develop methods for training preservice teachers to deliver mathematics instruction with both rigor and relevance within nurturing and empathetic learning environments that validate students' diverse worldviews and backgrounds. Suriati's scholarship critically examines representations of Muslim identities in children's and young adult literature. Drawing on her transnational experiences as a Malay Muslim educator in Singapore and the United States (Abas et al., 2020), she contributes a lens attentive to spatial belonging, cultural legitimacy, and epistemic inclusion. Matt approaches literacy as a civic and communal practice, examining how literature amplifies marginalized voices and fosters inclusive school communities. His work informs the framework's narrative strand and its commitment to counterstorying as a form of epistemic resistance. Lara's work and research as a mathematics teacher educator focuses on the conceptualization of mathematics identity and the role of curricular resources in shaping how learners position themselves as mathematics doers. Her scholarship grounds the framework's emphasis on identity development and disciplinary integrity. Collectively, our interdisciplinary collaboration reflects a shared commitment to reimagining mathematics education as a shared space where narrative, culture, and mathematical rigor intersect.

Theoretical Foundations

The proposed NEFG is rooted in literature that foregrounds the use of picture books as an instructional tool to connect students' worldviews, funds of knowledge, and cultural relevance to rich and meaningful geometry content. In this section, we share the theoretical foundations for this framework

Students' Funds of Knowledge and Culturally Relevant Pedagogy

With the growing, diverse student population in the United States, it is becoming crucial to design mathematical instructional plans and activities that include students' funds of knowledge and how they make sense of the world around them (Moll et al., 1992). Funds of knowledge

(FoK) is a term that was coined by Moll and colleagues and refers to the cultural and experiential insights held by students and their families, especially in multicultural settings. Within mathematics education research, FoK encompasses the varied mathematical understandings and practices that children from diverse backgrounds contribute to the classroom (Altaş et al., 2024). In addition, leveraging students' FoK serves as a vehicle towards equitable, inclusive, and meaningful mathematics education that builds upon the strengths of all students. When students' real-world experiences and cultural funds of knowledge are foundational to teaching, mathematics concepts and ideas become tangible, accessible, and meaningful (Marshall, 2023).

Leveraging students' funds of knowledge is a core tenet of theoretical frameworks that center student identities, such as culturally responsive pedagogy (Ladson-Billings, 1995), culturally sustaining pedagogies (Marshall, 2023), and culturally relevant mathematics teaching (Marshall, 2023; Zavala & Aguirre, 2024). While each framework is distinct in its own way, each of these theoretical perspectives prioritizes a deep consideration for designing student-centered instruction. Culturally relevant mathematics teaching provides students with access to rigorous mathematics learning experiences while also attending to the unique intersectional identities of students in the classroom (Zavala & Aguirre, 2024). Research found that culturally relevant and sustaining approaches to teaching mathematics inform the development of students' robust mathematics identities (Anderson, 2007), increase student achievement and interest in mathematics (Hunter & Miller, 2022), and significantly improve educational equity (Zavala & Aguirre, 2024). Hence, teachers are tasked with creating mathematically powerful learning environments that nurture students to become active participants and doers of mathematics (Huinker et al., 2020).

The construct of the term mathematics identity has gained increasing prominence in mathematics education scholarship, reflecting a broader sociocultural turn in the field (Darragh, 2016; Sfard & Prusak, 2005). While definitions of and perspectives on mathematics identity vary, most mathematics educators and researchers adopt a sociological view of mathematics identity. In this view, an individual consists of multiple dimensions of identity that are formed and reformed as the individual interacts in different social environments (Darragh, 2016; Wenger, 1998). In essence, mathematics identity can be viewed as the story we tell ourselves in relation to how we are positioned in mathematics learning communities (Sfard & Prusak, 2005). Starting elementary school, students begin to define themselves as math learners (Collins, 2018). This self-identity can be negatively impacted by school and community biases, content biases, differences in learning styles, and often untracked biases within instructional processes (Martin, 2013). These factors are all outside of the student's control and are often unreflective of their potential ability as mathematicians. For students to see themselves as mathematicians, they need to be provided with learning opportunities that draw on their funds of knowledge to support their content learning and the construction of robust mathematics identities (Varelas et al., 2012). With these considerations in mind, mathematics classrooms have considerable power in shaping students' mathematics identities, which in turn has a direct impact on students' ability to learn (Zavala & Aguirre, 2024). Historically, traditional mathematics classrooms that emphasize speed and procedural memorization of mathematics concepts have served to marginalize students and perpetuate social hierarchies (Martin, 2013). Increases in culturally responsive mathematics teaching offer promise to create spaces that support improved content learning and identity construction for elementary students. We argue that picture books could be anchored in geometry instruction to create counter-narratives that inform the development of robust mathematics identity.

Ethnomathematics

At the intersection of using diverse cultural contexts and understanding mathematical concepts, D'Ambrosio (1985) emphasizes the importance of ethnomathematics as a culturally inclusive teaching approach. From this perspective, *ethnomathematics* presents possibilities for instruction based on culturally relevant pedagogies. It empowers students through its ability to connect mathematical concepts to students' lived experiences, thereby facilitating deeper comprehension and retention. Ethnomathematics views mathematics as a product of diverse cultural practices and symbolic systems rather than a universal decontextualized body of knowledge (D'Ambrosio & Rosa, 2017; Hunter & Miller, 2020). Empirical and synthesis studies report benefits for engagement, conceptual understanding, and achievement when mathematics instruction integrates cultural content and interdisciplinary context that are relevant to students' real worlds (Averill et al., 2009).

Making clear connections between mathematics and students' culture, communities, and identities takes on multiple approaches and orientations. Research on the use of community processes in teaching and co-creating curriculum materials reports improvement in student belonging and instructional quality for diverse learners (D'Ambrosio & Rosa, 2017). Designing tasks around cultural artifacts (e.g., textiles, symbols, farming activities) offers comprehensible and accessible encounters that make mathematical concepts concrete, relevant, and meaningful, reinforcing inclusion and belonging and dismantling the narrow view of what mathematics is and who is a mathematics doer. A systematic literature review of studies published between 2021 and 2024 found that integrating ethnomathematics hat links mathematical context to cultural motifs and art in teaching plane geometry significantly enhances primary school students' numeracy skills (Zainovi et al., 2025). In turn, this promotes conceptual understanding and increases motivation (Zainovi et al., 2025). Ethnomathematics is especially valuable in diverse societies, accommodating varied cultural and linguistic backgrounds and empowering students through deeper learning. Multiple research studies examined the use of Islamic art as a context to explore Geometry concepts (e.g., Rita et al, 2022, Purniati at al., 2021) in a relevant and meaningful approach that *interlaces* (Rita et al, 2022) mathematics with history, culture, and art. In this way, ethnomathematics explicitly positions the learners' cultural repertoires as a legitimate source for mathematical knowledge, celebrating their histories, culture, language, and ways of knowing, which is critical for their robust mathematics identity development (Hunter & Miller, 2020).

Picture Books in Mathematics Teaching and Learning

Another line of research we draw upon for the NEFG is the use of picture books as an accessible and available means of integrating the aforementioned comprehensible cultural artifacts. Culturally-centered picture books also help build a learner's cultural repertoire, especially as our nation's political and social tensions are felt in classrooms (Ishizuka, 2018). We seek for the use of culturally-centered picture books and mathematics as integral components to a lesson, beyond the traditional use as an instructional hook. Introducing culturally-centered, authentic picture books may shape individual's cultural understandings and engagement with mathematics as they see the significant contributions of math in the larger world. Drawing from Rudine Sims Bishop's (1990) framework for books as windows, mirrors, and doors, we recognize the transformative potential of books to help readers understand themselves, each other, and the world at large. As Nancy Snow is cited with saying, "If we can't put [students of different backgrounds] physically together, we can give them other people's stories and talk about them" (Ishizuka, 2018). While Ishizuka's main argument stems from librarians advocating for diverse book collections, they also recognize the importance of diverse texts being integrated into school curriculum. Within practitioner spaces of education blogs and forums, educators

advocate for the value picture books add to instruction and for promoting classroom community, empathy, and understanding (Short, 2019; Thrower, 2025). Thrower (2025) notes that using picture books as a hook or introduction to a math concept helps students build connections to the content, thus making learning meaningful. There are curricula that are available with read alouds already paired to key standards, but there is also potential to work with trade/mass market books as authentic texts. These texts connect with readers as the protagonists grapple with problems similar to those students face—often in a more realistic way than a traditional math word problem.

Naseef, et al. (2024) found that contemporary picturebooks about Muslim children in the United States function as counternarratives, representing religious practice as integral to daily life and portraying Muslim families as culturally and religiously diverse. Their study challenges the misunderstanding that religion has no place in public school's curricula. Abas et al.'s (2021) extend Bishop's (1990) metaphor through a geocritical framework (Westphal, 2011) to foregrounds space as socially produced (Lefebvre, 1991), historically situated and central to identity formation. Through their critical content analysis of Muslim immigrant picture books, they demonstrate how fictional and real spaces intersect (Westphal, 2011) to shape the processes of adaptation, social negotiation and self-determination. Space, in this framing, is experienced, contested, and imbued with cultural meaning. This spatialized understanding offers a significant extension for mathematics education, particularly in geometry, where space is often abstracted from lived experience. Hence, when geometry instruction is situated within culturally embedded spatial practices such as Islamic architecture designs or tessellated artistic traditions, it reconnects mathematical reasoning (National Council of Teachers of Mathematics, 2000) to the social production of space (Lefebvre, 1991) and to students' identities as meaning-makers (Wells, 1986/2009). When there is no shared foundational knowledge, picture books provide a communal, immediately accessible experience to help students understand the content, local community, or even the larger world.

A complementary insight emerges in Abas (2025) where visual narratives are examined as multimodal sites shaped by power, authorship, and cultural mediation. This insight extends to mathematics classrooms, where geometric diagrams, patterns, and transformations function as multimodal representations that warrant critical interpretation aside from procedural consumption (Rau, 2017). However, integrating literature in such conceptually robust ways requires more than good intentions. Zhang et al. (2023) report that mathematics educators often possess limited pedagogical knowledge for meaningfully incorporating picture books as they perceive them "lack[ing] concrete pedagogical details" (p. 3) around which rigorous instruction can be organized. Purposeful scaffolding is, therefore, necessary to support mathematics teachers in leveraging picture books for both conceptual and cultural understanding. Empirical evidence from Abas (2026) further demonstrates that sustained engagement with Muslim-centered picture books can shift educators' assumptions and instructional dispositions. Through structured dialogue and critical reflections, teachers move beyond symbolic gestures of diversity toward deeper interrogation of identity, bias, and epistemic authority. These findings align with Tondreau and Yang (2025), who supported preservice teachers in using Asian American and Pacific Islander picture books to build community and cultural knowledge. Similarly, Baer (2017) used picture books to develop students' understandings of Muslim cultures, specifically looking at similarities and differences in schooling, play, and clothing.

Taken together, the scholarship suggests that picture books in mathematics classrooms should function as epistemological interventions. When educators integrate Muslim-centered narratives that foreground geometric design, spatial negotiation, and cultural meaning, students

are invited to engage with geometry as both mathematical reasoning (NCTM, 2000) and cultural inquiry (Pinxten, 1991). In doing so, the classroom becomes a space where mathematical understanding, identity formation, and cultural recognition intersect, expanding who is recognized as a producer of mathematical knowledge and broadening the epistemic boundaries of the discipline. The theoretical foundations of ethnomathematics, culturally responsive pedagogy, and funds of knowledge converge on a central imperative: mathematics instruction must center students' cultural practices and histories while interrogating the sociopolitical forces that shape whose knowledge is legitimized. Building on this scholarship, we conceptualize an approach to teaching geometry that intentionally integrates narratives, ethnomathematics and critical frameworks, and mathematical rigor to foreground culture and identity. In the following section, we delineate the intersection of these ideas to outline the strands of the NEFG.

Conceptualizing the Intersection: Geometry, Culture, and Identity

Teaching geometrical concepts like transformations and tessellations through the lens of Islamic histories and Muslim mathematical contributions provides a powerful, culturally sustaining framework that bridges abstract mathematics with tangible human heritage (Huda, 2025; Mubarak & Setyaningsih, 2025). By utilizing picture books and tasks anchored in ethnomathematics, educators can transform geometry into a tool for both academic excellence and social justice (Mubarak & Setyaningsih, 2025; Darragh, 2016; Voss & Rickards, 2016). Additionally, grounding mathematics instruction in the use of picture books facilitates a narrative-first approach that foregrounds storytelling by identifying "rich narratives" to support integrating mathematics with picture books (Russo & Russo, 2018, p. 8). This model fosters student engagement with comprehensive mathematical material by presenting it within relevant and meaningful contexts (e.g., narratives). Hence, picture books serve as instructional tools, rather than add-ons, which harness student imagination to conceptualize worlds beyond their classroom walls where they can solve real-life mathematical problems, such as determining the geometry of a prayer rug or identifying symmetry in architectural ornaments (Russo & Russo, 2018). This approach is also effective for contextualizing and differentiating mathematical experiences while teaching mathematical content. The use of picture books within this approach opens up instructional spaces to integrate diverse onto-epistemologies as well as interdisciplinary content. See Figure 1 for a list of suggested picture books to be used with this approach.

Figure 1: Recommended Picture Books that Could Be Used with the Narrative First Approach

Alongside the use of picture books, ethnomathematics is an instructional approach in which the mathematical context, task, and activities are rooted in students' cultures, languages, and

histories (D'Ambrosio & Rosa, 2017; Hunter & Miller, 2020). Nieto (2013) advocates for an education that connects the curriculum to the context of students' lived experiences. This empowers student voices and provides an opportunity for teachers and students to learn about, respect, and honor other cultures, experiences, backgrounds, and languages, and expands students' worldviews. Curriculum must move beyond superficial representation and "checking a box" to effectively educate students before issues of otherness or difference are brought into the classroom, or worse, when curricula promote Islamophobic stereotypes (CAIR Foundation, 2025). We must be proactive in creating empathetic spaces in our schools, where students can find commonalities and connections with each other. For Muslim students, this means having a space to pray and even having dietary needs met. Schools should reflect, represent, and celebrate students' histories, languages, and cultures to improve academic success and foster consciousness. Because Islamic art and architecture present a culturally embedded source of geometric patterns (Bier, 2015), we argue that an interdisciplinary instructional approach that foregrounds students' stories, imagination, and histories through picture books and ethnomathematics creates meaningful opportunities for students to learn mathematics. Geometry, in particular, as a mathematical content, lends itself well to cultural and historical connections for Muslim students as a context allowing them to see their identities reflected in the mathematical knowledge (Massarwe et al., 2012). It showcases the mathematical artistry of the Islamic civilization and decolonizes the Eurocentric grounding of the mathematical knowledge.

At the intersection of the aforementioned ideas and theoretical foundations, we propose the NEFG as an interdisciplinary pedagogical model designed to anchor and integrate students' narratives and ethnomathematics to weave culture, identity, and sense-making within mathematical learning. It encompasses three strands that inform each other and are interwoven and enmeshed to create a dynamic instructional space (see Figure 2). While these strands are numbered, they do not reference a hierarchical or processional order. The numbers are a means of helping teachers and researchers to enter into this work, selecting the strand they are most familiar with and expanding from there to the others. We conceptualize these strands as follows:

Strand I: Narratives as Humanizing and Epistemic Entry Points

This strand advocates for a narrative-first approach (Russo & Russo, 2018) that utilizes picture books as an instructional tool to facilitate students' engagement, context relevance, and representation in the curriculum. Drawing on Bishop's (1990) idea of windows, mirrors, and doors, these diverse narratives introduce students to real-life and historical contexts that decolonize the traditional, linear, and neutral views of mathematics. During this strand, the use of picture books rooted in culturally relevant pedagogies elicits students' narratives and storytelling to foreground world views and histories.

Strand II: Ethnomathematics as Cultural Historical Grounding

This strand highlights ethnomathematics as a core instructional approach that disrupts the traditional, Eurocentric, and culturally-neutral notions of mathematics to create ethical educational spaces that celebrate students' counterstories and sense-making. This creates inclusive spaces where students' participation and contributions inform the development of their robust mathematics identities. In this section, students undertake mathematical activities that use real-world contexts, thereby creating opportunities for representing and decolonizing the mathematics curriculum.

Strand III: Mathematical/Disciplinary

This strand is informed by research on how students develop their identities as mathematics *doers* by focusing on ensuring rigorous and meaningful mathematical learning experiences that

lead to mathematical proficiency. In this strand, the teacher facilitates the rigor and the richness of the mathematics learned to foreground conceptual mathematics.

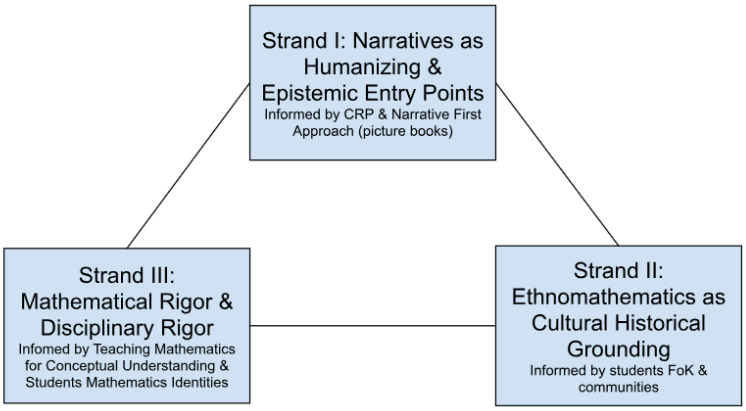

Figure 2: The Narrative-Ethnomathematics Framework for Geometry (NEFG)

We assert that these strands should be evident in any geometry instructional plan that aims at providing a minoritized student population with access, representation, and opportunity to do meaningful mathematics. Additionally, we recognize that the conceptual nature of our framework necessitates a clearer definition of "geometry" to guide application. We align our view with the work of Nurnberger-Haag (2017), which highlights the importance of precision in early shape instruction to prevent the entrenchment of common misconceptions.

Pedagogical Implications

The NEFG offers pedagogical implications beyond mathematics education by providing teachers and mathematics teacher educators with an interdisciplinary model that informs the planning and development of powerful instruction. While we focused on using geometry to connect sociohistorical Islamic contexts for decolonizing mathematics and creating ethical learning spaces for Muslim students, this approach can apply to other subjects and student populations. Integrating ethnomathematics and culturally grounded narratives challenges Eurocentric curricula by recognizing learners' cultural backgrounds—such as Islamic art and architecture—as valid sources of geometric knowledge (D'Ambrosio & Rosa, 2017; Hunter & Miller, 2020). This model reimagines geometry instruction as a culturally sustaining practice that connects abstract concepts like transformations and tessellations to real-world cultural heritage, supporting the development of strong mathematical identities and deeper conceptual understanding (Hunter & Miller, 2020; Zainovi et al., 2025).

Moving Forward

Future iterations of this framework will explicitly define the geometric concepts—such as classification, transformation, and property analysis that our three-strand model aims to support, ensuring that instructors can apply these strands to design tasks that challenge Eurocentric biases while maintaining mathematical rigor. Building on this work, our future research focuses on the application of the NEFG. Also, this work will be extended to the teacher education program curriculum to serve as a guide for preservice teachers to support them in planning and enacting culturally relevant mathematics teaching that promotes identity development and equitable learning.

This study examines how 18 monolingual and emergent bilingual preschoolers used gesture, language, and movement as they noticed structures while comparing and transforming contrasting tangram figures. Findings indicate that gesture and deictic language functioned as primary resources for indicating similarities and differences, supported by translanguaging. The recognizable figures supported comparison through background knowledge and everyday language. These results highlight the importance of multimodal and multilingual approaches to early geometry instruction and suggest that sequencing tasks from familiar to abstract configurations may support the development of spatial language and reasoning.

Keywords: Geometry and Spatial Reasoning, Early Childhood Education

Spatial reasoning is central to early geometric thinking because it involves noticing structure, coordinating parts within a whole, and supports reasoning about how relations change under movement and reorientation (Clements & Sarama, 2009; National Research Council, 2006). Although state standards do not explicitly isolate spatial reasoning as a separate domain, noticing structure is central to identifying, composing, and decomposing shapes and understanding geometric relationships (Clements & Sarama, 2009). Young children often notice composite figures holistically before they can systematically compare embedded components, track correspondences across two designs, or anticipate the transformations needed to make them match (Clements & Sarama, 2009; Loewenstein & Gentner, 2001; National Research Council, 2006). Emerging research suggests that language can support children's geometric and spatial reasoning (Hallowell, 2020; Owens, 2015) along with experiences focused on structural relationships (Mulligan et al., 2004). The role of language is particularly important to consider within today's multilingual learning environments, where children may draw on multiple linguistic resources while developing mathematical ideas.

Shape puzzle tasks provide opportunities for children to explore how shapes can be composed, decomposed, and transformed. Prior research suggests that transformation can be particularly challenging when pieces appear in non-prototypical orientations and that repeated opportunities to work across orientations can promote flexibility (Bofferding & Aqazade, 2023; Bofferding & Zhu, 2023). Comparison tasks encourage children to notice differences between composite figures may support the development of structural awareness (Schwartz & Bransford, 1998). Yet an important question remains: how do children engage in noticing and comparing structural differences before they have fully developed geometric vocabulary?

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Gesture may play a critical role in this process (Alibali, 2005). Young children often rely on pointing, tracing, and coordinated manipulation to communicate spatial relationships when verbal language is still developing. Gesture and movement can function as cognitive and communicative tools that support reasoning about shape, orientation, and position. Flexible use of multiple languages (translanguaging) may further support multilingual learners' participation and meaning-making during spatial tasks by allowing children to access concepts through whichever linguistic resources are most available (Tai, 2022; Wei, 2018).

This study examines how preschool children use gesture, language, and movement while comparing and transforming composite tangram figures. In particular, we investigate how children indicate similarities and differences between contrasting figures and how they reconcile those differences through manipulation and language. We also explore how translanguaging supports these processes for emergent bilingual learners. By examining children's engagement with both recognizable and abstract composite figures, this study aims to illuminate how multimodal and multilingual resources support early geometric and spatial reasoning.

Theoretical Frameworks

Central Conceptual Structure for Geometry (Central Geometric Structure)

Extending Case's theory of Central Conceptual Structures (1996), Hallowell (2020) describes early geometric reasoning through the coordination of two precursor schemas. An *imagistic precursor schema* supports recognizing prototypes of shapes (e.g., circle, square, equilateral triangle sitting on base) and overall figure appearance, but can limit attention to embedded components and to the magnitude and direction of transformations (Clements & Sarama, 2009; Hallowell, 2020). A *verbal-declarative precursor schema* helps children name and describe shapes and features, often through everyday labels and informal descriptors. (Clements & Sarama, 2009; Hallowell, 2020). By age 6, children integrate their earlier schemas and can discuss shape properties and identify geometric features, though they tend to attend to only one set of features at a time (Hallowell, 2020). They can also locate shapes within shapes and perform transformations more accurately and intentionally, but may not be predicting these transformations in advance (Clements & Sarama, 2009; Hallowell, 2020).

Translanguaging and Multimodality

Translanguaging offers a heteroglossic perspective on bilingualism, emphasizing that emergent bilinguals draw from an integrated linguistic repertoire rather than alternating between bounded "languages" (García & Wei, 2014; Otheguy et al., 2015). In mathematics activity, this flexibility allows children to draw on whichever linguistic resources best support their participation and reasoning. From a multimodal perspective, meaning making extends beyond speech to include gesture, gaze, spatial arrangement, and manipulation (Jewitt, 2008; Kress & van Leeuwen, 2001). In early geometry tasks that rely on pointing, modeling, and transforming objects, linguistic and embodied resources work together to support spatial reasoning. Together, translanguaging and multimodality form the core meaning-making processes in our framework, aligning with the semiotic and cognitive foundations of early spatial reasoning.

Current Study

The current study builds off of prior research by giving young children experiences to analyze and manipulate targeted combinations of shapes. Our research questions are as follows**:** 1) How do preschoolers use gestures and language to indicate the similarities and differences between contrasting tangram puzzle pictures? How does translanguaging support this process for emergent bilinguals? 2) How do preschoolers reconcile the contrasting tangram puzzles'

differences by changing one version of the puzzle into the other through movement and language?

Methods

Participants and Setting

The participants for this study included 18 preschoolers (ages 3–5) who attended a university preschool program or a play-oriented daycare. Preschoolers' home languages included Mandarin (n=8), English (n=4), Spanish (n=3), Tamil (n=1), Farsi (n=1), and Odia and Hindi (n=1). Instruction at the preschool and daycare was provided in English. During the interviews, we gave multilingual Spanish and Mandarin speakers the option to speak in their home language or English as they wanted. The Spanish speakers primarily chose to respond primarily in Spanish, sometimes switching to English. Most Mandarin speakers responded in English; only one Mandarin-speaking pair regularly used Mandarin. Within this pair, when the interviewer shifted between English and Mandarin, the children sometimes matched the interviewer's language in the moment. Preschoolers chose their own pseudonyms.

Procedures

The data for this paper come from session two of a four-session study focusing on preschoolers' spatial language, reasoning, and their composing of shapes. In session one, we identified preschoolers' baseline ways of talking about and working with shapes and space (see Bofferding et al., 2025). In session two, the focus of this paper, we worked with preschoolers in pairs–two students worked along with an interviewer–and had them complete two main tasks together: a tangram puzzle comparison task and a copy-cat task. Our focus here is on the former task. For the tangram puzzle comparison task, we showed each pair two versions of a completed cat tangram puzzle (see Figure 1A) and asked, "What's the same and different between the two puzzles? *(¿Qué hay de diferente entre los dos rompecabezas?* "*这两个图形有什么相同和不同吗？*"). "How are these puzzles put together differently?*" (¿Cómo están armados estos rompecabezas de manera diferente?* "*这两个拼图是如何被不同地拼起来的?")*. After they compared them, we set up tangram pieces as shown in the right picture and asked them to change it so that it matched the left picture. "Can you make them the same?" *(¿Cómo los haces iguales?* "*你们能把它们俩变得一样吗?*") We repeated this process for a second set of hourglass tangram puzzle pictures (see Figure 1B). Between the two cat puzzles, the images differed in the orientation and placement of the orange parallelogram and in the orientation of the small blue triangle, emphasizing differences in non-embedded pieces but highlighting relative positions. In the hourglass puzzle, the differences were clustered in the bottom-right portion of the image, emphasizing differences in embedded pieces and requiring attention to shapes within a larger configuration. Due to space, we focus on the results for the cat puzzle in this paper.

Figure 1: A. Contrasting Cat Tangrams and B. Contrasting Hourglass Tangrams

Analysis

After transcribing the sessions, we coded the transcripts in Dedoose (Version 10.0.59) using the language framework developed by Cannon et al. (2007), which we modified to include subcodes related to gestures and if they are self-corrected. When coding, we coded the entire interaction where the language or gesture happened so we could capture the context. We then looked across transcript codes for how they talked about and gestured related to similar areas of the puzzle and grouped them by similarities, differences, and attempts to make them look the same so we could identify trends and differences across the pairs.

Table 1: Language Codes (based on Cannon et al., 2007)

Code	Description and Examples
Code-switch	Participant alternates between two or more languages or varieties of language in conversation.
Translanguaging	Participant draws upon different linguistic, cognitive and semiotic resources to make meaning and make sense.
Gestures	Participant uses a gesture rather than language to communicate their answer to a question. The subcode *two-handed* indicates when they used both hands simultaneously.
Background knowledge	Words that make connections with children's everyday world/self.
Continuous amount	Words that are used to describe continuous quantities.
Deictics	Words that are place deictics/ pro-forms (i.e., these words rely on context to understand their referent). The subcode *generic shape* indicates the deictics took the place of a shape name.
Location/direction	Words that describe the relative position of things in space. The subcode *using mat/manipulative* identifies instances where location was referred to relative to the images.
Shapes	Words that describe the standard or universally recognized two- and three-dimensional objects and spaces.
Spatial dimension	Words that describe the size of objects and spaces.
Spatial features/ properties	Words that describe the features and properties of objects, spaces, people. The subcode *color* indicates a non-mathematical property of the shape.
Spatial orientations/ transformations	Words that describe the relative orientation or transformation of objects in space.
Comparisons	Words that indicate what is the *same*/*similar*, *different*, and *not same* between objects or shapes.

Results

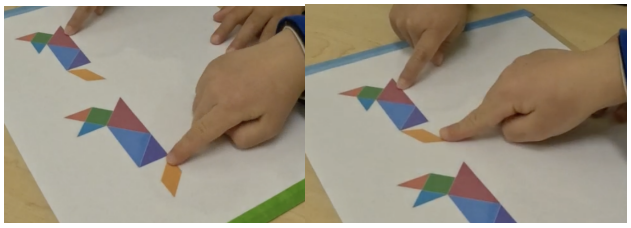
From Holistic Recognition to Structural Comparison

When shown the initial set of contrasting "cat" tangram puzzles, four pairs identified both images as cats, and one called each a fox. Interestingly, five pairs gave different names to the two images (e.g., cat versus dog, cat versus baby, cat versus cow, or fox versus bed or bird), suggesting that differences were noticed early even at the level of whole-figure interpretation. In describing similarities, participants frequently drew on background knowledge and labeled meaningful parts of the figure. For example, Mister stated, "They have ears, bodies, legs, and tail," indicating that the animals shared the same parts and treating the composite shapes as a coherent organism rather than as a set of geometric components. Several pairs similarly referenced the "body" as the same (often pointing to the large triangles), indicating attention to global structure prior to attending to embedded shapes. However, prompts to compare specific details supported a shift from holistic recognition toward structural comparison; when asked whether the ears were "exactly the same," Mister indicated they were not, often pointing to the corresponding ears as he compared them.

Gesture as a Resource in Comparative Reasoning

Across the pairs in our dataset, all noticed the two differences, with six pairs and one individual noticing the triangle ears as different first and two pairs and one individual noticing the parallelogram tails as different first. No pairs needed prompting to notice that the tails of the two cats were different. When asked what was different, Marfin and Snow first pointed to the ears in the right-hand cat (see Figure 2A). When asked whether the turned-down ear was the same as the other cat's ear, Snow shook her head and responded, "不是" *("No")*. While two pairs required an explicit prompt to state whether the ears were the same or different, most pairs made this comparison without prompting.

Across episodes, participants often coordinated pointing with spatial orientation language when describing ear differences. For instance, Superman stated, "the ear is down, and the ear is up" while pointing to each ear in turn. Deictic talk (e.g., "this one") commonly appeared alongside pointing, suggesting that gesture and deictic reference served as key resources for comparative reasoning when precise shape names were limited.



A.  B. 

Figure 2: Joint Pointing of A. Marfin and Snow and B. Big Train and Small Train

Participants also described tail differences readily, typically using location and orientation language (e.g., top/bottom; up/down) in coordination with gesture. For example, Pumpkin explained, "This one's on the top… and this one's connected by the bottom," while moving her finger between the two figures. In another interaction, Big Train interrupted his peer's Small Train repeated deictics ("This is…this is…") to localize the contrast: "No! Because of these!" while pointing directly to the two parallelogram "tails", isolating a specific region of difference (Figure 2B). Across these episodes, pointing helped treat familiar part-based interpretations (e.g.,

animal parts) as comparable units, enabling pairs to decompose the figure and sustain comparisons of orientation and placement.

Translanguaging as Conceptual Access in Spatial Reasoning

Translanguaging practices were observed in connection with both shape naming and spatial reasoning, allowing emergent bilingual participants to draw flexibly on their full linguistic repertoires while engaging with the task. For example, Bella, a Spanish-speaking preschooler, used both English and Spanish labels when discussing the cat's head, referring to the shape as both "square" and "*cuadrado*." Interestingly, she first referred to the square as a "rectangle," demonstrating both her bilingualism and her background knowledge, since "rectangle" was not a shape explicitly introduced during instruction. She also used both "triangle" and "*triángulo*," fluidly combining languages in expressions such as "*un* triangle *chiquito*" ("a small triangle"), which she repeatedly to explain the differences between the two pictures and to describe how to make them the same. These examples suggest that translanguaging supported access to geometric reasoning by allowing participants to draw on whichever linguistic resources were most available at the moment.

Translanguaging also supported participation and conceptual access through flexible shifts between languages within interaction. In an exchange between Rosa and Olivia, two Spanish-speaking preschoolers, Rosa initially recognized the figures by saying "*¡Son gatitos!*" ("They are kitties!"). When Olivia hesitated, the researcher switched to English, prompting Rosa to respond again in English, which Olivia then adopted ("Cat!"). This fluid, dynamic bilingualism appeared to lower participation barriers and enabled both participants to engage in subsequent reasoning about orientation and rotation. For example, Rosa later explained, "*Su oreja está torcida…pero su otra oreja no está torcida*" ("This one's ear is crooked, but this other one's ear is not crooked"), demonstrating awareness of differences in orientation between corresponding shapes.

Across bilingual interactions, spatial language related to orientation frequently emerged through coordinated gesture and translanguaging. For instance, Big Train explained the difference between the two ear triangles by stating, "This is low, and this is at the top," (Figure 3), and when asked to repeat, reiterated, "This is down, this is up," while pointing between the two ears. Similarly, Bella indicated "*La colita es para arriba*" ("the little tail is up") while pointing to the parallelogram in the left picture and then followed with "*Y esta es para abajo*" ("and this one is down"), making a downward motion with both index fingers to mark orientation. In these examples, spatial language (up/down; *arriba/abajo*) was tightly coordinated with pointing and vertical tracing gestures, suggesting that participants encoded differences primarily through orientation rather than through geometric naming.

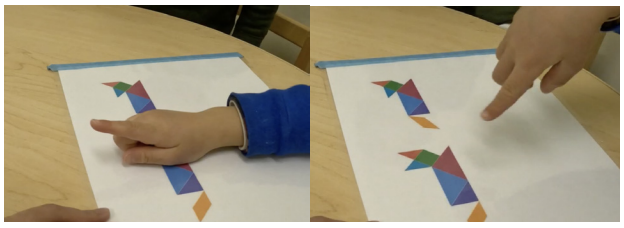


Figure 3: Big Train Indicating Up (left) and Down (right)

A similar pattern was observed in interactions conducted in Mandarin. For example, Snow stated, "这是下, 这是上" ("This one is down; this one is up") while pointing between two

parallelograms and tracing along each piece's slanted edge with her finger. When prompted to extend the comparison, Marfin applied the same language to the ear triangles, again labeling one as "up" and the other as "down" while pointing between them. This sequence suggests that participants used translanguaging to map relational concepts across different components of the figure, extending the same orientation framework from ears to tails.

Together, these interactions highlight how translanguaging supported participation, comparison, and transformation reasoning within the task. Rather than relying solely on one language, participants flexibly combined linguistic and gestural resources to anchor deictic references ("this one") to specific regions of the figure and to communicate spatial relationships. Gesture appeared to function as a stabilizing resource across languages, enabling participants to maintain coherent spatial reasoning even when lexical access varied.

Reconciling Differences Through Movement and Language

When they tried to fix the cat on the right to look like the left one, participants often combined manipulation, gesture, and language to reconcile the differences. Pinky suggested, "Turn it the same as this one," while pointing between corresponding ears (the small blue triangles) on the two figures, indicating awareness that orientation changes could resolve the discrepancy. In several cases, movement preceded verbal explanation. For example, Butterfly rotated a parallelogram to match the target orientation while Mister adjusted its placement, commenting, "A little downer," and sliding the piece to align with the base. These interactions illustrate how embodied actions supported spatial reasoning during the transformation process, consistent with the idea that manipulation and gesture can mediate early geometric reasoning. Their discussion of how to align the tails focused mostly on location and orientation.

Discussion and Implications

In our dataset, gesture and deictic language played a central role in how children indicated similarities and differences and reconciled the contrasting tangram images. Within these interactions, children frequently relied on pointing and expressions such as "this one," "here," or "there," often before or in place of specific shape labels**.** From a Central Geometric Structure perspective, this pattern is consistent with children recognizing the overall structure of the figure while still developing verbal resources for explicitly isolating component parts and describing transformations (Clements & Sarama, 2009; Hallowell, 2020). In these episodes, pointing helped stabilize reference to specific parts and supported aligning correspondences across the two images. These findings suggest that gesture functioned as a primary semiotic resource that supported spatial reasoning when lexical resources were still emerging. Rather than viewing imprecise language as a limitation, the coordinated use of gesture, manipulation, and speech reflects a multimodal process through which children constructed meaning. This pattern aligns with prior research suggesting that embodied actions can mediate early geometric reasoning and support the development of more formal spatial language over time (Ehrlich et al., 2006; Iverson & Goldin-Meadow, 2005; Goldin-Meadow, 2009; Goldin-Meadow et al., 2012).

The recognizable animal structure of the cat puzzles appeared to serve as a semantic anchor that allowed children to leverage background knowledge to identify and compare parts. References to ears, tails, and bodies enabled children to decompose the composite figure even when geometric vocabulary was limited. These everyday part labels can be understood as verbal–declarative resources that supported decomposition of the composite figure, even when conventional geometric naming was not available (Clements & Sarama, 2009; Hallowell, 2020). More abstract configurations (e.g., the hourglass puzzles) may lack familiar referents and may

initially invite global judgments of sameness; future work could examine whether such tasks also support more explicit analytic reasoning about orientation and placement.

Prompting also shaped children's comparisons. In this task, questions that directed attention to specific components or asked how to make the two figures the same were often associated with shifts from holistic judgments toward part-by-part comparison and transformation talk. This finding extends work showing that guided comparison supports alignment of representations and noticing shared relations (Loewenstein & Gentner, 2001) and aligns with developmental perspectives on coordinating imagistic and verbal–declarative resources through guided experiences (Hallowell, 2020).

Translanguaging further supported participation and reasoning for emergent bilingual children. In our data, flexible language use expanded children's moment-to-moment access to spatial terms during comparison and repair, while gesture helped maintain shared reference across language shifts. Together, these findings reinforce viewing multilingual resources as assets for mathematical meaning-making.

Overall, our results highlight the value of multimodal and multilingual resources in early spatial reasoning. For task and instructional design, the findings suggest prompts that guide children from whole-figure identification to aligning corresponding parts, legitimizing deictic talk paired with pointing, and leveraging relational language about orientation and location (e.g., up/down; top/bottom) and translanguaging as bridges toward more conventional geometric naming. Future research could examine how sequences of familiar and abstract spatial tasks shape the development of geometric language and transformation reasoning over time, particularly in multilingual learning environments.

Recent developments of generative artificial intelligence (GAI) tools have opened intense discussions regarding their use in mathematics education. We argue that teachers' consistent and coordinated use of these resources opens novel paths to complement dynamic problem-solving strategies. The research question that guided the study was: What ways and patterns of reasoning do high school teachers develop when they coordinate a customized ChatGPT problem-solving assistant with GeoGebra to work on mathematical problems? Eight practicing high school teachers worked on a set of problems that involved concepts that appear in algebra, geometry and calculus courses. Results indicate that coordinated use of a customized Socratic Problem-Solving Assistant and a Dynamic Geometry System (GeoGebra) allowed the participants to transit among visual, geometric, and analytic reasoning to develop concepts understandings and mathematical problem-solving competencies.

Keywords: Mathematical Problem Solving, GeoGebra, ChatGPT, Problem-Solving Assistant, High School Teachers

Introduction, Background, and Research Questions

Humans have always designed and use a diversity of tools to cope with their physical environment as well as with the functioning of their cultural environment and mental work including mathematical teaching and learning scenarios. What tools and how can teachers and students use them to understand mathematical concepts and to develop problem-solving competencies? Ruthven (2019) introduces the construct "resource system" to refer to, "the various mathematical tools and curriculum materials in use in the classroom and the way in which their use—individually and collectively—is organized and made functional" (p. 51). To understand how teachers develop a productive way to rely on a variety of tools, it is necessary to analyze the tool appropriation process through which learners internalize a set of affordances to represent, explore, and solve mathematical problems (Santos-Trigo, 2024). Within digital environments, resources like Dynamic Geometry Systems (DGS) and Generative Artificial Intelligence (GAI) apps can be coordinated to nurture and frame mathematical practices. To manage the complexity of these human and machine interactions and to guide the mathematical command process, this coordination can be conceptualized through the lens of instrumental orchestration (Trouche, 2004).

In this study, we focus on documenting the extent to which high school mathematics teachers integrate the coordinated use of a customized ChatGPT Problem-Solving Assistant (PS-A)—acting as a Socratic tool—and GeoGebra as a dynamic environment in their teaching practices. Thus, the research questions that guided this study were:

What ways and patterns of reasoning do high school teachers develop and apply when they coordinate the use of a ChatGPT problem-solving assistant with a Dynamic Geometry System (GeoGebra) to work on mathematical problems? And how could their emerging problem-solving experiences orient their teaching practices?

Essentials of a Conceptual Framework: The Relevance of Subjects' Tool Appropriation in Mathematical Problem-Solving Activities

Schoenfeld (2011) argued that to understand and explain what people do when they are involved in "well practiced" activities, one needs to delve into individuals or group's goals, the type of resources that people bring to a situation including their base knowledge and tools, and people's orientations that are expressed in terms of their belief about mathematics and their teaching. An overarching goal in teaching and learning scenarios is to provide conditions for learners to engage them in mathematical practices to understand and construct concepts and to work and solve mathematical tasks. To this end, teachers and students rely on diverse tools to represent, explore and grasp concepts or make sense of problem statements and to look for different ways to work on mathematical tasks and to communicate, and extend mathematical results (Santos-Trigo, 2024). In this context, students' resources or tool appropriation is a key process for them to transform resources or tools into an instrument to achieve mathematical goals or to work on mathematical tasks. This subjects' tool appropriation is relevant because it shapes their thought process and actions involved in approaching mathematical tasks. Teachers and students conceive of or think of those resources as a set of affordances that they rely on to engage in rich collections of mathematical activities and practices. Thus, subjects' thinking system gradually constructs cognitive schemata or some consistent patterns of behavior that are applied to perform mathematical tasks. Reintroducing digital technologies into this structure not only enhances and expands the subjects' pathways of reasoning about approaching mathematical tasks, but also provides novel routes for them to represent, explore, solve, and communicate problem solutions or results (Moreno-Armella, 2021; Santos-Trigo, 2024). Arcavi (2020) pointed out that "some tools not only enhance our capabilities by 'augmenting a signal' but they may also enable us to do completely new things that one could not undertake without them" (p. 422). To frame the coordinated use of GAI tools and GeoGebra affordances, it is essential to leverage what tools' affordances subjects activate to work on mathematical tasks:

1. Dialogic-Reflective Reasoning (GAI Affordances): The use of GAI tools privileges the use of natural language to establish a continue dialog between the tool and the user to explore and engage in different ways of reasoning while dealing or approaching mathematical tasks. Focusing on the design of a ChatGPT assistant implies to guide the problem solver to navigate through all problem-solving phases (Polya, 1945) instead of receiving a direct answer or problem solution. Through a Socratic approach, subjects engage in a productive dialog by answering sequential questions posed by the PS-A throughout all problem-solving stages. This category systematically evaluates how participants formulate, revise, and refine prompts, analyze tool outputs, and deploy metacognitive skills to deal with potential tool hallucinations.
2. Dynamic-Geometric Reasoning (DGS Affordances): GeoGebra affordances offer teachers and students an opportunity to model and explore mathematical concepts and problem dynamically by moving orderly objects within the model. This exploration becomes important for learners to transit among visual, numeric, geometric, and algebraic representations to detect and analyze invariants or patterns associated with mathematical relationships.

The dual analysis that reconciles learners' pencil and paper and digital work opens innovative routes for learners to represent, explore and connect visual and geometric meanings of concepts with objects' mathematical properties and results (Moreno-Armella and Santos-Trigo,

2016). Under this framework, a new epistemology of school mathematical knowledge emerges, expressed through combining visual, empirical, graphic and analytical approaches to identify and support mathematical relations and solution paths. This is manifested in how the ways of conceiving mathematical objects evolve in terms of the user's activation of technology affordances to explore concepts and problem solutions, allowing individuals to experience a distinct materiality through the malleability and plasticity of digital representations (Moreno-Armella and Hegedus, 2009).

Research Design, Participants, and Procedures

The nature of this study is qualitative since there is interest to delve into the participants' problem-solving experiences and sense-making processes to work on mathematical tasks through the coordinated use of a PS-A and GeoGebra. Eight practicing high school teachers participated voluntarily in a problem-solving seminar within a professional development program. The seminar included face-to-face weekly problem-solving sessions held during one semester for 4 hours each session. During the initial sessions, the participants reviewed recent research on GAI tools and focused on the collaborative design of a problem-solving assistant. Indeed, the option of creating customized GPTs was officially introduced by OpenAI through providing templates for configuring ChatGPT for specific tasks (OpenAI, 2023). Guided by the seminar coordinators, the participants introduced specific instructions, parameters, and information into each component associated with the configuration template provided by the platform to ensure the PS-A worked and behaved as a Socratic tutor. Figures 1 and 2 show part of the information that the group of participants introduced into the assistant template and its initial interface.

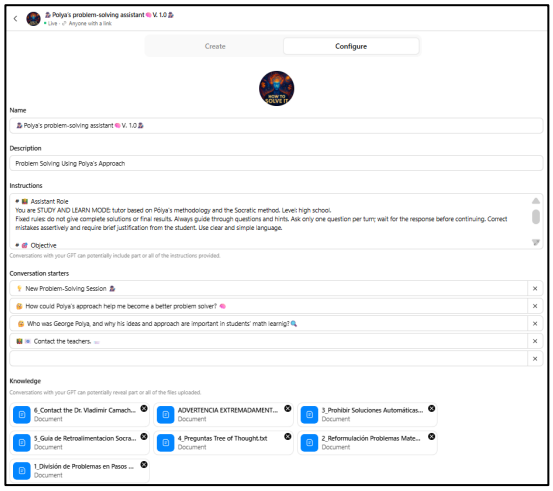

Figure 1: Configurating the Problem-Solving Assistant

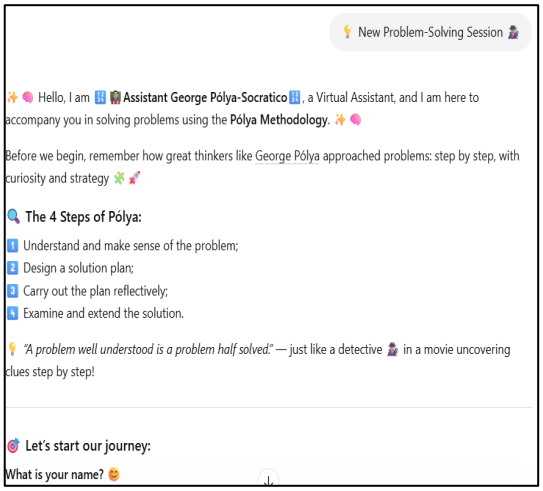

Figure 2: Initial User Interaction with the PS-A, Focusing on Polya's Stages

Although the course coordinators guided the process of introducing pertinent information to design the PS-A, the participants actively contributed to the creation of the assistant collectively and subsequently used it in pairs during the problem-solving sessions to approach the tasks in combination with GeoGebra.

Data Collection and Data Analysis

The unit of analysis included the pairs' problem-solving work that was registered in the problem-solving assistant chatbox conversation and written reports of the use of GeoGebra to work on the task and episodes of the collective discussion during the pairs' presentation to the group. To analyze these data, we applied a coding scheme focused on identifying patterns of reasoning (visual, empirical, geometric and analytic) and tracking the participants' transitions through Pólya's problem-solving phases. The integration and triangulation of these data during the analysis contributed to the trustworthiness of the study.

Presentation of Results

To present the main results of the study, we analyzed what the participants did during the solution process of the circle problem. This task is representative of the type of problems that the participants worked on during the sessions. Data came from the dialog that pair-1 reported during its interaction with the PS-A and the pair-3's use of GeoGebra to work on the same task. The approaches involved the use of the PS-A that guided the participants to navigate throughout problem-solving phases and the use of GeoGebra to dynamically represent, explore, and solve the task. Thus, pair prompts and answers to the problem-solving assistant determined transitions through problem-solving stages.

The Circle Task

A circle with center O and a radius of five units is drawn, a line that passes through the center of the circle intersects the circle at points A and B. P is any point on the radius OB. Draw a perpendicular line to OB through point P. This perpendicular intersects the circle at points Q and R (Figure 3). When point P is moved along radius OB a family of triangles AQR is generated, find a position for point P where the area of triangle AQR reaches its maximum value.

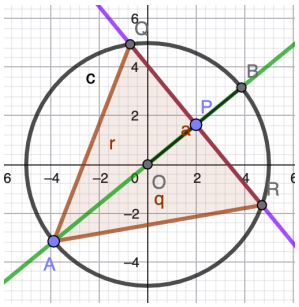

Figure 3: The Circle and a Family of Triangles

The problem statement was the initial prompt introduced to the PS-A which guided pair-1 to follow Polya's phases to work on the task. Pair-1 presented this dialog to the whole group in which all participants identified and discussed relevant moments related to the process. In Table 1, the first column shows a selection of prompts provided by pair-1 and comments to contextualize them. The second column includes the assistant responses. It is important to observe that the PS-A indicated when the pair could transit from one phase to the next one based on the pair inputs (a complete dialog between pair-1 and the PS-A can be consulted in this link).

Table 1: Excerpts from Pair-1 Dialog with the PS-A

Pair-1 Prompts or Answers and Comments	The Problem-Solving Assistant Answers
When pair-1 introduced the circle task statement, the words "the area" after the term "where" was missed; but the assistant directed the pair to the understanding phase to clarify the statement.	✨🧠 Hello, I am 🔢👩‍🏫**Assistant George Pólya-Socratico**🔢, and I will guide you step by step like a true problem-solving detective! 🕵️‍♂️💡 Let's recall the **Pólya Method**: 1️⃣ Understand the problem 2️⃣ Design a plan 3️⃣ Carry out the plan 4️⃣ Reflect and extend
At this stage, the Assistant posed a question about key elements of the problem, and the pair's answer was: A circle, a movable point P on a radius, perpendicular to the radius through P and a family of triangles associated with the position of P The pair wrote: *From the family of triangles* AQR *to locate a position for P where the area of triangle* AQR *gets the maximum value*	*What are the key elements (data and geometric objects) given in the problem*? —Then, the Assistant asked to focus on specific figure: **What exactly is the problem asking you to determine about triangle AQR?** The Assistant answer was: *You clearly identified the goal:* ***maximize the area of triangle AQR****. That's powerful* 💪📐 ✅ **Conclusion of Step 1:** You understand both the elements and the objective. —Here, the assistant posed questions related to the plan design
The pair answer was: *First, drawing the circle with center at the origin of the Cartesian system. That is, its equation will be x^2 + y^2 = 25* The pair wrote: *The coordinates for P could be* (*x,* 0) *and the coordinates for A and B will be* (-5, 0) *and* (5, 0). *The* Q *and* R *coordinates will be* (*x,* (25-*x*^2)^1/2 *and* (*x,* -(25-*x*^2)^1/2 *respectively the base will be the length of* QR *and the height the length AP* This dialog led pair-1 to express the triangle area as: $A(x) = (5 + x)\sqrt{25 - x^2}$ and to rely on calculus concepts to determine that when x = 2.5 triangle AQR reaches its maximum value. In addition, an emerging property was identified: The solution corresponds to the midpoint of OB. Pair-1's answer was:	STEP 2: Design a plan 👉 ***Question (only one!):*** ***Can you think of one way to express or calculate the area of triangle AQR in terms of the position of point P?*** Great idea! You're thinking like a true mathematician—bringing geometry into coordinates is a powerful strategy, just like turning a real-world problem into a formula 💡🚀 Placing the circle at the origin is an excellent start: $x^2 + y^2 = 25$ ***How would you represent the coordinates of point P on the radius OB in this coordinate system?*** 🤔 👉 ***Question:*** ***If the vertical line through*** $P = (x, 0)$ ***meets the circle*** $x^2 + y^2 = 25$***, what coordinates do you get for*** Q ***and*** R***?*** 🤔 👉 ***Question:*** ***Using triangle*** AQR***, what could you choose as its base, and what would its corresponding height be?*** 📐🤔 👉 ***Question:*** **What strategy do you want to use next to maximize** $A(x) = (5 + x)\sqrt{25 - x^2}$**: derivative, squaring the expression, or another idea? Briefly justify your choice.**

because one always finds a way to translate or move the Cartesian system keeping invariant the structure of the problem	✅ Step 4 is complete. Very good. Now let's see if you can extend this reasoning. 👉 Question: What is the geometric position of P on radius OB when $x = 2.5$? 🤔📐 —The Assistant posed a final conceptual question: 👉 **Final Question:** **Why does placing the problem in a convenient coordinate system NOT change the final answer of the optimization problem?** 🤔📘

Comment: There is evidence that the questions and guidance provided by the PS-A to approach the task not only directed pair-1 to navigate through problem-solving stages; but also, they became relevant for pair-1 to think of the task in terms of concepts that were relevant to construct the area model of the problem. Situating the center of the given circle at the origin of the Cartesian system was a key strategy to reduce the task complexity. Thus, applying calculus concepts (derivative, critical points, etc.) helped pair-1 to solve the task and to identify that the solution corresponded also to the midpoint of OB. In the group discussion, it was recognized that the geometric meaning of the derivative as the slope of the tangent line of the area function could be further explored with the use of GeoGebra.

The coordination between resources was organically supported within the seminar's framework. Rather than positioning one tool as subordinate to the other, the learning environment encouraged participants to transit between the discursive-analytic register of the PS-A dialogue and the dynamic-visual register of GeoGebra. This interplay facilitated a synergistic relationship where the algebraic properties and answers (or Socratic answers) from the chatbox conversation continuously informed and were enriched by the geometric configurations and variation parameters explored within the dynamic environment.

A GeoGebra approach to this circle task. During the pair-3 presentation and discussion with the whole group, the participants focused on representing a geometric model that included the task conditions. With center at the origin O, a circle with a radius of five units was drawn. A line that passes through the center O intersects the circle at points A & B, and P is a movable point on radius OB. When point P is moved along OB a family of triangles AQR is generated. How does the area of this family of triangles behave when point P is moved along OB? To visualize this, point S was drawn with *x*-coordinate the same *x*-coordinate of point P and as *y*-coordinate the corresponding area of triangle AQR. Indeed, the GeoGebra affordances allow to graphically visualize the area variation generated for any position of point P (Figure 4). The purple graph represents the locus of point S. During the group analysis, it was observed that for any point T on the locus and a tangent line to this locus at T, its slope varies; when the tangent line becomes parallel to the *x*-axis, the slope value is zero, reaching its maximum value.

Comment: During the group discussion, it was recognized that the use of GeoGebra offers affordances to visualize key elements of the task to make sense of the problem statement. The group discussion led the participants to determine that at point M (midpoint of OB), the area reaches its maximum value of 32.48 units and at this point the slope of the tangent line gets the value of zero (Figure 4). In addition, another result emerged: Triangle ADE at this position becomes an equilateral triangle. At this stage, the participants contrasted both approaches to this task and argued that while the PS-A seems to privilege the construction of an algebraic model of the task and its analysis through calculus concepts, the GeoGebra approach focused on the geometric meaning of involved concepts to visualize the behavior of key mathematical relations.

More importantly, the coordinated use of both tools allowed the participants to connect and transit between algebraic and geometric ways of reasoning, linking symbolic expressions with dynamic visual representations of variation. In this process, the tools did not operate as isolated resources; but rather as complementary mediational systems that supported and expanded the participants' opportunities to make sense and coordinate symbolic and geometric approaches.

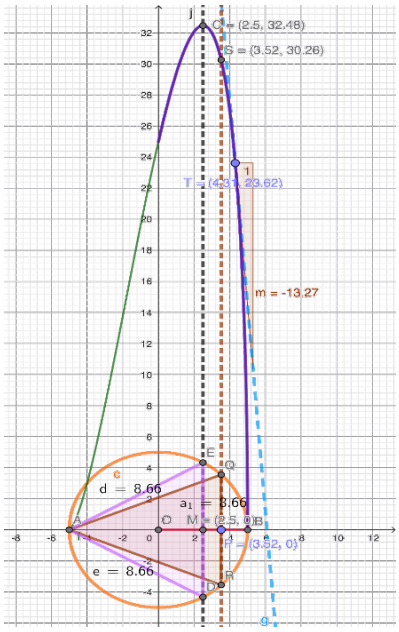

Figure 4: A Dynamic Model to Determine the Maximum Value of Area Variation of the Family of Triangles AQR

Discussion and Final Remarks

The significant and constant digital developments including GAI tools have generated intense debate on not only what role they should play in students' mathematical learning, but also, what adjustments or reforms are needed in mathematical curriculum and teachers' education programs to fully integrate those tools in learning environments. In this study, high school practicing teachers had an opportunity to integrate two tools in problem-solving activities: a PS-A that does not provide direct solutions but guides users to navigate through problem-solving phases via a Socratic approach, and GeoGebra to dynamically represent, explore, and solve mathematical problems. In this coordinated use, participants recognized that their interaction with the PS-A demanded that they constantly refine and review the prompts introduced to engage in a productive conversation with the tool to transit through problem-solving stages. There is evidence that the pairs' interaction with the PS-A directed and shaped their ways to decide what concepts and strategies to follow to work and solve the task. Designing prompts that effectively elicit the desired responses from LLMs is a complex task that often requires iterative refinement and domain expertise, a complexity that "can be a barrier for educators who may not have the resources or expertise to develop and evaluate optimal prompts" (Chen et al., 2024, p. 10).

Likewise, the participants relied on the use of GeoGebra affordances to model and explore problems dynamically. To this end, they needed to think of mathematical concepts and problem statements in terms of geometric properties or meaning. For instance, in the circle task, the

participants associated the position of point P on segment OB with the corresponding area of the generated triangle AQR at that position to delve into the area variation of the family of triangles. It becomes relevant to discuss what changes the coordinated use of several digital tools brings to the study of mathematical concepts. The construction and exploration of dynamic configurations offer a distinct path to study optimization problems. A salient feature is recognizing that the formulation of prompts and ways to analyze the tool's outputs are key activities that learners need to engage in to gradually construct robust prompts that guide them in developing problem-solving competencies. Learners need to problematize the tool's outputs to make sense of what is involved and what part of the output needs further explanation.

A distinguished feature of GAI tools is that users can formulate prompts in natural language. This affordance not only offers an opportunity to extend the types of questions the user wants to explore but also to engage in problem-posing activities that emerge during the task solution process. For instance, the dialogue with the PS-A led the participants to transform the initial geometric problem into a variation task that required calculus concepts to solve it, information that they subsequently modeled geometrically (with GeoGebra) to extend the initial nature of the task.

Finally, our exploratory findings suggest that teachers' interaction with these tools can influence and help shape their approaches to mathematical tasks. By engaging in this dual integration, the participating teachers showed indications of developing aspects of Dialogic-Reflective and Dynamic-Geometric reasoning, while reflecting on the cognitive demands that might be required to orchestrate these resources in their classrooms. The coordinated use of a Socratic PS-A and GeoGebra could support a transition in mathematical activity from merely finding an answer toward a multi-representational inquiry process, suggesting tentative pathways to consider for future pedagogical practices. Looking forward, this study outlines potential dimensions for a future research agenda. First, exploring the design of specialized assistants tailored for punctual tasks could provide insights into how educators might guide tool behavior around specific learning objectives. Second, further research could examine instructional workflows where diverse digital tools are systematically combined to support mathematical goals. In this regard, studying how teachers and students engage with these combined digital environments represents an open avenue to further clarify the cooperative role of Generative Artificial Intelligence and Dynamic Geometry Systems in mathematics education.

TRANSFORMING VISUALIZED SPATIAL REASONING INTO GEOMETRIC JUSTIFICATION: A RANDOMIZED PILOT OF GEOGEBRA-BASED DYNAMIC GEOMETRY SIMULATIONS FOR PROOF PREPARATION

Zhen Zhang
Florida State University
zz23i@fsu.edu

Lesleigh Philips
Academy Prep St. Petersburg
lphillips@academyprep.org

Yukyeong Song
University of Tennessee
ysong51@utk.edu

This randomized pilot examined whether GeoGebra-based dynamic geometry simulations improved Grades 7–8 students' 2D–3D spatial reasoning and proof preparation. Twenty-eight students were randomized to simulations or parallel non-dynamic instruction across nets, cross-sections, and congruence. Baseline and immediate post-assessments showed strong rater agreement on constructed-response subtotals (ICC pre = .97; post = .92). ANCOVA controlling for baseline favored simulations (adjusted M = 14.38 vs. 11.34), F (1, 25) = 42.08, p < .001, partial η^2 = .627, with consistent gain-score difference (Δ = 2.00), t (26) = 2.985, p = .006. Results indicate promising short-term effects and inform future retention and transfer analyses.

Keywords: Dynamic Geometry Simulations, 2D–3D Representational Coordination, Spatial Reasoning, Geometric Justification

Purpose

Geometry is a core strand of secondary mathematics and a gateway to abstract reasoning (Noor & Alghadari, 2021). Many students struggle with proof because it requires coordinating spatial reasoning, logic, and multiple representations, while typical instruction often provides limited support for unfolding solids, anticipating cross-sections, and justifying diagram-based claims (Haj-Yahya et al., 2022; Fujita et al., 2020; Okamoto & Romo, 2015; Sudirman et al., 2023). This pilot tests whether GeoGebra-based dynamic simulations improve students' spatial reasoning and geometric argumentation for proof preparation, compared with parallel non-dynamic instruction, by strengthening 2D–3D representational coordination through tasks on nets, cross-sections, and congruence. Given limited classroom-embedded randomized evidence, we estimate immediate effects to inform a future delayed-post phase examining retention and within-domain transfer (Adams et al., 2022; Zhang et al., 2023).

RQ1: How does participation in GeoGebra-based dynamic geometry simulations affect post-assessment spatial reasoning and justification after controlling for baseline?

RQ2: How do pre- to post-improvements in geometric justification for proof preparation differ between GeoGebra-based dynamic simulations and parallel non-dynamic instruction?

Theoretical Framework/Perspectives

This study is grounded in spatial reasoning theory, van Hiele's theory of geometric thought, and cognitive load theory (Naufal et al., 2021; Seah & Horne, 2020). These perspectives explain why students may struggle with geometry tasks that require coordinating visual, spatial, and logical reasoning. Spatial reasoning involves mentally and visually operating on geometric objects, such as rotating, unfolding, slicing, and connecting 3D structures with 2D representations (Lowrie et al., 2019; Judd & Klingberg, 2021). In line with van Hiele's theory, visualization supports students' movement from recognizing figures by appearance toward using properties, relationships, and logical claims for emerging proof (Fitriyani et al., 2018; Nahdi et

al., 2024; Miyazaki et al., 2017; Haj-Yahya et al., 2022). Cognitive load theory further informs the design because 2D–3D transformations can burden working memory when students rely only on internal imagery or static diagrams (Paas & Van Merriënboer, 2020; Rivella et al., 2021; Buckley et al., 2019; Okamoto & Romo, 2015).

Accordingly, 2D–3D representational coordination is defined as connecting actions on three-dimensional solids with corresponding two-dimensional representations, including nets, cross-sections, diagrams, and written explanations (Fujita et al., 2020; Lowrie et al., 2019). GeoGebra-based dynamic and interactive geometry environments may support this coordination by making transformations visible, manipulable, and reversible, helping students observe relationships difficult to infer from static representations alone (Moreno-Armella et al., 2008; Ng et al., 2020; Zhang et al., 2023). Guided by these perspectives, spatial reasoning and early-stage geometric justification are the primary outcome constructs. The randomized comparison tests whether structured visual manipulation improves immediate spatial reasoning and supports stronger geometric argumentation after controlling for baseline performance.

Methods

Research Design

This pilot employed a two-condition, parallel randomized controlled design embedded in routine middle school instruction. Students were assigned within class to GeoGebra-based dynamic simulations or a parallel non-dynamic comparison matched on goals, pacing, and task sequence, with the key contrast in representational modality and interaction. Pre-/post-assessments with rubric-scored written work examined short-term learning and proof-oriented reasoning. Although a larger phase will add a delayed post-assessment 5~6 weeks later to examine retention and within-domain transfer, this report focuses on immediate pre–post effects.

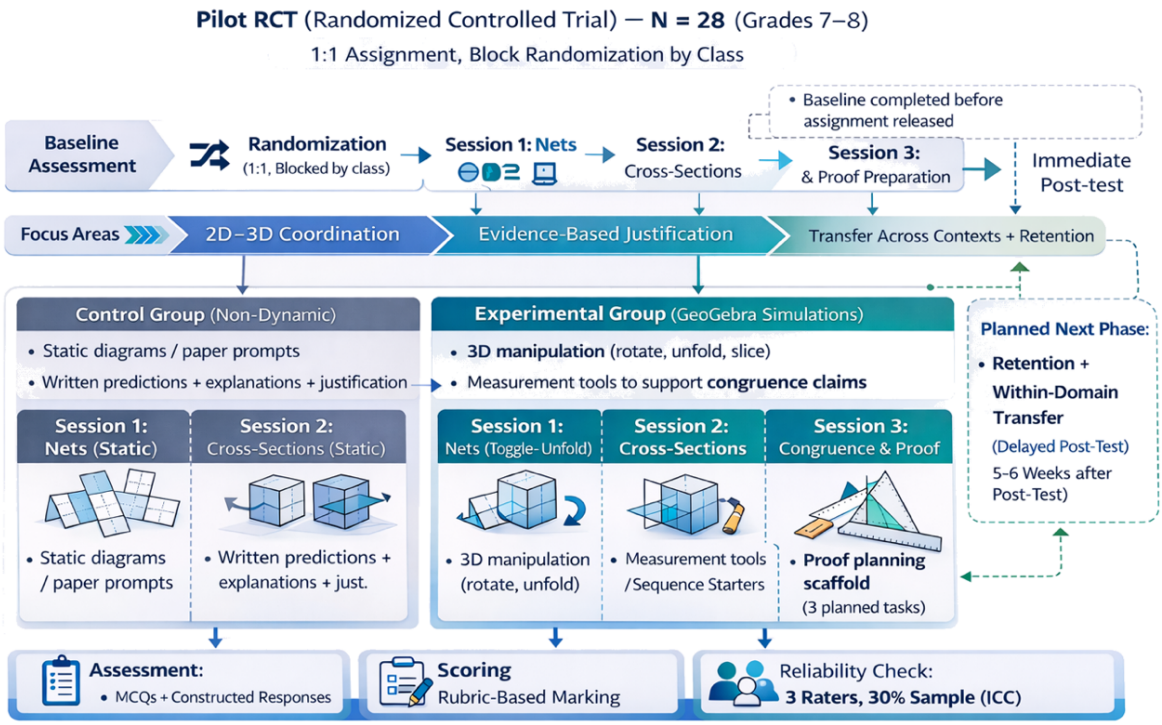

Figure 1: RCT Procedures and Intervention Pathway Across Sessions

Procedures and Data Collection

Participants were 28 students in Grades 7–8 at a Florida middle school, randomized 1:1 to control (n = 14) or experimental (n = 14). Across three interventions: Nets, Cross-sections, Congruence-based proof preparation, both groups completed parallel activities. The experimental group used GeoGebra 3D models to unfold nets, rotate solids, manipulate slicing planes, examine intersection traces, and apply measurement tools to support congruence claims. The control group completed the same sequence with non-dynamic materials (static diagrams and paper prompts). After Session 3, students completed identical pre-/post-assessments with multiple-choice and constructed-response items that were rubric scored to produce a geometric argumentation subtotal, with reliability established by three raters (see Figure 1).

Analysis and Reliability

Primary inference used ANCOVA with post total score as the dependent variable, condition as the factor, and baseline total score as the covariate. An independent samples gain-score t test provided a secondary check. A parallel ANCOVA examined the post constructed-response subtotal controlling for baseline. Three raters scored a 30% subset of constructed responses, and interrater agreement was evaluated with ICC at both time points to establish scoring consistency.

Findings

Data analyses examined the pilot sample (N = 28, 14 Control ~ 14 Experimental) and focus on baseline and immediate post-assessment outcomes after the three-session intervention.

Table 1: Immediate Post Total Score Results (RQ1): ANCOVA and Gain-score t-test

Outcome	Control	Experimental	*P*	Effect / 95%CI	Test statistic
Post Total adjusted mean (SE)	11.34 (0.32)	14.38 (0.32)	< .001	partial η^2 = .627	ANCOVA Group: F (1, 25) = 42.08
Post Total 95% CI	[10.68, 12.00]	[13.72, 15.04]			
Covariate Pre Total			< .001	partial η^2 = .677	ANCOVA Covariate F (1, 25) = 52.37
Gain Total mean (SD)	2.29 (1.33)	4.29 (2.13)	.006	CI [0.62, 3.38] (Exp − Ctrl).	t-test (Gain): *t* (26) = 2.985

Note. ANCOVA modeled *Post total* ~ group + *Pre total* (adjusted mean at *Pre total* = 9.57). *Gain total = Post total – Pre total*. Two-tailed *p* values are reported.

ANCOVA on post total, controlling for pre total, showed a clear simulation advantage, F (1,25) = 42.08, $p < .001$, partial $\eta^2 = .627$, with higher adjusted post means for GeoGebra than control (14.38 vs 11.34, SE = 0.32). Gains told the same story: simulations improved more (4.29, SD = 2.13) than control (2.29, SD = 1.33), t (26) = 2.985, $p = .006$, 95% CI [0.62, 3.38]. This supports RQ1 by suggesting that even a short GeoGebra simulation sequence strengthens immediate geometric performance and conceptual visualization because students were able to visualize and manipulate 2D–3D relationships (e.g., unfolding, rotating, slicing, dimensionality measurement) rather than relying on static procedures, making spatial relationships easier to coordinate and justify.

Table 2: Constructed Response for Geometric Argumentation (RQ2) and Reliability

Measure	Control (n = 14) M (SD)	Experimental (n = 14) M (SD)	Test statistic
Pre GeoArgument	3.14 (1.35)	4.29 (2.13)	Gain *t*-test:
Post GeoArgument	3.86 (1.96)	6.29 (1.44)	t (26) = 2.30, p = .030
Gain (post−Pre)	0.71 (1.33)	2.00 (1.62)	95% CI [0.14, 2.43] (Exp − Ctrl)
ANCOVA adjusted Post GeoArgument (SE)	4.21 (0.37)	5.93 (0.37)	ANCOVA group effect: F (1, 25) = 10.39 p = .004
Interrater agreement (ICC, single)	Pre: .97 [0.92, 0.99]	Post: .92 [0.78, 0.98]	partial η^2 = .294

Note. Pre/Post GeoArgument are rubric scored. ANCOVA adjusted post means at pre = 3.71. ICC with three raters on a 30% subset (n = 8). Two tailed p values are reported.

GeoGebra group showed larger gains in justification: argumentation increased by about 2 rubric points (M gain = 2.00, SD = 1.62) versus less than 1 point in the control (0.71, SD = 1.33), t (26) = 2.30, p = .030, 95% CI [0.14, 2.43], and the advantage held after baseline adjustment (5.93 vs 4.21, SE = 0.37; F (1,25) = 10.39, p =. 004, partial η^2 = .294). Scoring consistency indicates strong (ICC=.97 pre /.92 post). It suggests simulations supported proof preparation by helping students ground written claims in geometric features and relationships rather than unsupported statements from static representations, which is central for developing proof readiness.

Conclusion and Implication

This pilot provides initial evidence that GeoGebra-based visual simulations can strengthen students' immediate geometric learning and proof preparation after a brief three-session sequence. For RQ1, the simulation group outperformed the comparison group on overall post-performance after controlling for baseline, F (1,25) = 42.08, p < .001, partial η^2 = .627. For RQ2, students using simulations showed stronger growth in constructed-response justification and a higher adjusted post level, F (1,25) = 10.39, p = .004, partial η^2 = .294, with strong scoring consistency (ICC = .97 pre / .92 post). These results suggest that dynamic visualization can support conceptual visualization and written claims grounded in geometric features and relationships central to proof preparation.

Instructionally, the findings support short simulation-based task sequences that make spatial invariants observable and prompt students to articulate what changes and what remains invariant. Pairing dynamic manipulation with targeted prompts that connect observations to formal language and justification (e.g. correspondences, invariance, transformation-based reasons) may be especially productive for developing proof-oriented reasoning.

The findings are preliminary given the small sample size, single site, and focus on immediate outcomes. However, the consistent advantages across overall performance and argumentation provide clear justification to proceed to the next phase. The planned study will add a delayed post-assessment five or six weeks after the post to examine whether gains in spatial reasoning.

THE COW TASK: DESIGN OF PIAGETIAN-STYLE TASK TO ASSESS CHILDREN'S UNDERSTANDING OF PERPENDICULARITY

Clare Bassano

Keywords: Early Childhood Education, Geometry and Spatial Reasoning, Cognition

The purpose of this study is to develop, implement, and analyze the results of a Piagetian-style task using an interactive tool to assess children's understanding of perpendicularity.

Theoretical Framework

To assess understandings of parallelism, Piaget and Inhelder (1998) asked children to predict what happens when lazy tongs are opened. However, they did not develop any perpendicularity tasks. Existing research about preschoolers and perpendicularity focuses on static shapes; e.g., of children aged 3–6, older children are better at identifying non-square rhombuses as not squares (Clements et al., 1999). As Piaget and Inhelder (1998) assert, "what we must endeavor to concentrate on is not […] static shapes, but rather their transformations" (p. 304).

Task Design and Implementation

Our tool consisted of four blocks of wood of equal dimensions attached by hinges, so that children could collapse or extend the rhombus. Children were shown how the tool (or "fence") could be manipulated and given time to change the shape independently. Children were told, "change the shape of the fence to give [your cow] the most room" and asked, "How did you know to make the fence like that?" The task was administrated as part of video-recorded individual clinical interviews in a larger study. Participants included 42 4- to 5-year-old children (M_{age} = 4.71 years, SD = 0.42).

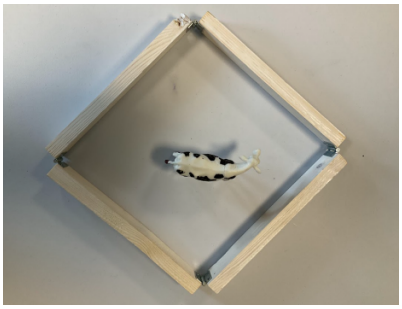

Figure 1: Tool Used in Task to Assess Preschoolers' Concepts of Perpendicularity

Results

Children had a strong bias towards squares, explicitly or implicitly. Many children referenced squares in their response, e.g. "because it's a square" (child 217, 4yr 0mo). Other children identified rotated squares as diamonds, e.g. "a diamond has more space" (child 234, 5yr 0mo).

Objectives and Theoretical Framework

In the present study, we evaluate the impact of GeometryByExample—a worked example-based intervention co-developed in a close research-practice partnership—for supporting learning of basic and high school Geometry content. The ByExample approach involves providing strategically designed, worked-example based assignments for students to complete in class in place of more typical practice assignments; instead of solving all of the practice problems themselves, students study correct or incorrect examples of solutions to half of the problems and respond to prompts asking them to write explanations of why those procedures are correct or incorrect. This approach draws on empirical evidence which has amassed from laboratory studies from three practices supported by the Science of Learning: worked examples (Sweller & Cooper, 1985), self-explanation (Roy & Chi, 2005), and learning from errors (Siegler, 2002).

Methods

Students (N = 348) in 17 intact high school Geometry classrooms in the United States completed measures of basic (pre-test, mid-year, and end-of-year) and high school Geometry knowledge (mid-year and end-of year). All classrooms received business-as-usual instruction from their teachers throughout the course; in classrooms randomly assigned to the experimental condition, teachers were asked to use GeometryByExample assignments to replace typical practice assignments they would use in their classroom, while students in control classrooms completed their normal practice assignments. Intervention dosage was computed as the number of self-explanation prompts attempted by a student.

Results and Implications

Results from the present study yielded significant effects of intervention dosage, indicating that experiencing greater levels of exposure to GeometryByExample materials led to greater learning of basic geometry content by mid-year, and greater learning of high school geometry content both at mid-year and by the end of the school year. The present study demonstrates that the ByExample approach can be beneficial for older students and can be incorporated successfully into classroom practice for more complex mathematics.

EXAMINING CRITIQUE ARTICULATION QUALITY IN PROSPECTIVE ELEMENTARY TEACHERS' EVALUATIONS OF AI-GENERATED GEOMETRIC JUSTIFICATIONS

Research has shown that many prospective elementary teachers (PTs) rely on intuitive or visual explanations rather than constructing logically valid and generalizable justifications (Kaur Bharaj & Cross Francis, 2020; Runnalls & Hong, 2020). Although PTs' levels of geometric justification have been examined (Segal et al., 2018; Zeybek, 2017), less is known about how to support reasoning that bridges visual intuition and formal justification (Stylianides et al., 2016), particularly when AI generated explanations are included into learning contexts. Building on recent work on AI in mathematics education (Son et al., 2024; Yoon et al., 2024), this qualitative study (Kalu & Bwalya, 2017) examines how PTs critique AI-generated geometric justifications in geometry content courses.

Fifty PTs from two public universities in the United States participated in the study and evaluated five AI-generated geometric justifications embedded as a course assignment. Using a critique-based approach (McGalliard & Otten, 2025), PTs analyzed AI responses related to two- and three-dimensional shapes and their properties. For example, when given the claim, "If the diagonals of a quadrilateral are congruent, it must be a rectangle," PTs critiqued a measurement-based AI response and provided written feedback on how to improve the justification by explicitly distinguishing rectangles from other quadrilaterals with congruent diagonals. PTs used an adapted version of Level 0–3 justification rubric (Brunheira & Ponte, 2019) emphasizing geometric definitions, logical sequencing, and generalizability. The data constituted how PTs identified missing components in the AI responses using the rubric, and suggested ways to improve.

Using thematic analysis (Xu & Zammit, 2020) on PTs' written critiques, we named a category focused on articulation quality, defined as how clearly and mathematically PTs identified missing mathematical components in AI-generated justifications and how actionable their proposed suggested were. Three patterns emerged under this category: (1) *Mathematically Substantive Improvement (56%)*: PTs explicitly named missing definitions, logical steps, or generalizability and proposed concrete revisions. (2) *Minimal or Vague Improvement (35%):* recognized incompleteness but offered underspecified suggestions (e.g., "needs more explanation"), limiting the usefulness of their critiques. (3) *No or Incorrect Improvement (9%):* PTs provided no improvement suggestions or proposed revisions that were mathematically irrelevant or incorrect, relying on broad statements without referencing core geometric ideas.

Data analysis revealed that PTs frequently critiqued measurement-based or example-bound reasoning and suggested revisions that emphasized explicit properties and logically sequenced and generalizable arguments. While many PTs demonstrated emerging capacity to articulate evidence-based improvements, others struggled to translate evaluative judgments into precise mathematical feedback. These findings underscore the importance of instructional support that explicitly targets how PTs identify missing reasoning and articulate substantive improvements

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

when critiquing AI-generated justifications, positioning critique not only as an evaluative act but as a core practice for developing robust geometric reasoning in AI-mediated learning environments.

Relating angle and rotation is an important and challenging concept for elementary students (Sinclair & Bruce, 2015). Specifically, students often have difficulty viewing a static angle as a rotation (Mitchelmore, 1998). This concept is especially challenging when one of the rays forming the angle is invisible (Mitchelmore & White, 2000), which is the case for exterior angles of a polygon. Scholars have found success in using bodily movements (Smith et al., 2014) and coding and robotics (Kim et al., 2021) to help students better understand angles.

As part of our ongoing project to integrate coding and robotics into mathematics in elementary classrooms, our partner teachers created a task that addresses this challenging concept of a partially visible static angle as rotation. Although the main objective of the task was about characteristics of polygons and not specifically about exterior angles of polygons, students naturally engaged in reasoning about exterior angles as they personally traveled along the edges of a polygon and as they programed a desktop robot to travel the path of a polygon, creating a trace image.

Using a distributed perspective (Evans et al., 2011), we seek to understand how students reason about a partially visible static angle as rotation. We will present an analysis of a segment of discourse of a student pair consisting of the students' words, movements, and gestures mediated by their tools and figures. In this segment, two students move a small toy along a quadrilateral to assist them to write pseudocode for a desktop robot to travel the same path. The students correctly identified the first turn, where the interior angle was obtuse, as an acute turn. At the second turn, they mistakenly identified the turn as 35 degrees, which was what they estimated the measure of the interior angle to be. At the third turn, where the interior angle was obtuse, a student said "that's [the turn is] definitely not obtuse" as she physically turned the small toy sweeping the exterior angle.

Our initial analysis shows that these students often reasoned mathematically by using object-level coreferences to the figure that represents the robot they would eventually code. Specifically, at the third turn, physically turning the figure and having to articulate the number of degrees seems to be the catalyst for the students to start attending to the exterior angle instead. The results imply that coding and robotics provide a both a context and a set of tools to support students to reason about partially invisible angles as rotations. These results add to the existing literature on ways coding and robotics can be used in elementary mathematics education (e.g., Boote & Galanti, 2023; Dunbar & Rich, 2020) by highlighting the affordances of coding and robotics integration.

ELEMENTARY TEACHERS' APPROACHES TO PROBLEM POSING AND SOLVING IN DIVISION CONTEXTS

Teruni Lamberg
University of Nevada, Reno
Terunil@unr.edu

Diana Moss
University of Nevada, Reno
dMoss@unr.edu

This study investigated elementary teachers' conceptual understanding of division through the dual lenses of problem posing and problem solving. Participants (N=28) generated word problems for 34 ÷ 6 (pre-test) and 48 ÷ 8 (post-test). Posed problems were analyzed using an analytic framework encompassing multiplicative structures (e.g., equal groups) and qualitative features, including linguistic clarity, explicit equal-grouping constraints, and contextual variety. While participants exhibited a robust default preference for partitive division and equal-groups structures, the post-test results revealed a significant shift. Following a targeted professional development intervention, the frequency of measurement division models increased, as did the mathematical precision and clarity of the posed problems. These findings suggest that intentional professional learning can effectively broaden teachers' conceptual repertoires and enhance their ability to construct mathematically rigorous instructional tasks.

Keywords: Number Concepts and Operations, Problem-Solving, Professional Development, Teacher Knowledge

Division word problems serve as a critical window into learners' conceptual understanding of multiplicative structures and the underlying meanings of division. In mathematics education research, two fundamental models are commonly distinguished: partitive (sharing) division, where the number of groups is known and the size of each group is sought, and quotative (measurement) division, where the group size is known and the number of groups is sought (Fischbein et al., 1985; Greer, 1992). Since a single numerical expression can represent divergent semantic structures, mathematical proficiency depends not only on computational accuracy but also on the ability to interpret and construct situations that align with the intended meaning of the operation. This "representational flexibility" is essential for developing a robust understanding of rational numbers and proportional reasoning (Mulligan & Mitchelmore, 1997).

Problem Posing

The process of generating new mathematical problems or reformatting existing ones has emerged as a powerful practice for both developing and accessing conceptual depth (Cai et al., 2013; Silver, 1994). When educators and students pose division story problems characterized by clear inquiry, equal-group structures, and diverse contexts, they are better positioned to externalize underlying mental models and connect abstract symbolic operations to meaningful scenarios. However, existing literature suggests that teachers, including preservice candidates, often possess a limited "pedagogical problem-posing toolkit." Research indicates that educators frequently default to familiar, stereotypical contexts, such as sharing food, and exhibit a significant bias toward partitive over measurement division (Luo, 2009; Osana & Pelczer, 2015). This reliance on a single model can inadvertently limit students' exposure to the breadth of multiplicative situations required by modern rigorous standards, such as the Common Core.

MATHEMATICAL KNOWLEDGE FOR TEACHING

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

The Study

This study investigates elementary teachers' understanding of division word problems through the dual lenses of problem posing and problem solving. By analyzing the "mathematical work" teachers perform when constructing problems (Ball et al., 2008), the research examines how teachers:

(a) Construct word problems corresponding to specific division expressions;
(b) Represent partitive versus measurement meanings and;
(c) Attend to key qualitative features, including linguistic clarity, explicit equal-grouping constraints, and contextual variety.

Theoretical Framework

Research on multiplication and division word problems emphasizes that divergent semantic structures can elicit distinct cognitive strategies and varying levels of difficulty, even when the underlying numerical operation remains constant (Fischbein et al., 1985; Greer, 1992; Verschaffel et al., 2000). In mathematics education research, division is fundamentally categorized into two conceptual models: partitive (sharing) and measurement (quotative).

In a partitive model, the dividend (total) and the number of groups are known, while the size of each group is the unknown to be determined. This model is psychologically associated with "fair sharing" actions and is often the first model students encounter (Mulligan & Mitchelmore, 1997). Conversely, in a measurement model, the dividend and the size of each group are known, while the number of groups serves as the unknown—a situation often modeled by "measuring out" or repeated subtraction. These relationships are summarized in Table 1.

Table 1: Known and Unknown Quantities in Multiplicative Situations

Operation	Number of Groups	Size of Each Group	Product (Total)
Multiplication	Known	Known	Unknown
Partitive Division	Known	Unknown	Known
Measurement Division	Unknown	Known	Known

Beyond these primary models, researchers identify several multiplicative structures used to frame word problems, categorized by the nature of the quantities involved (Carpenter et al., 1999; Vergnaud, 1983):

- Equal Groups: Situations involving fair sharing or repeated measures.
- Multiplicative Comparison: Comparing two quantities to determine how many times larger one is than the other (e.g., "three times as many").
- Cartesian Product: Determining the number of possible pairings between two sets, representing a product of measures.
- Area and Other Products of Measures: Problems involving rectangular arrays or physical dimensions where two measures are multiplied to produce a third, different unit.

Within equal-groups structures, problems typically emphasize either fair sharing (aligned with partitive meanings) or rates and measures (frequently associated with measurement meanings).

Criteria for High-Quality Division Word Problems

To ensure division word problems are mathematically well-specified and instructionally effective, this study identifies three essential qualitative features derived from the literature on mathematical task design and teacher knowledge (Ball et al., 2008; Silver, 1994):

- Clarity of Inquiry and Quantities: High-quality problems must clearly define the known quantities so that the specific unknown is unambiguous. Ambiguity in problem phrasing can lead to "situational difficulty" that is independent of mathematical complexity (Verschaffel et al., 2000).
- Explicit Equal Grouping: The text must explicitly state that groups are equal in size (e.g., "each person received the same amount") to distinguish formal mathematical division from informal distribution. Without this constraint, the problem is mathematically underdetermined.
- Contextual Variance and Authenticity: Problems should utilize diverse, meaningful contexts that extend beyond "cliché" examples, such as sharing cookies or candies. Authentic contexts help students bridge the gap between abstract operations and the varied real-world applications of division (Palm, 2008).

These three criteria serve as the primary analytic framework for evaluating the problem-posing tasks in this study, reflecting the "Specialized Content Knowledge" (SCK) required to teach division effectively.

Method

This study utilized a qualitative research design, supplemented by descriptive quantitative summaries, to evaluate the conceptual nature of teachers' posed word problems. Adopting a pre-test/post-test framework, the study examined shifts in teacher practice following a targeted intervention. In each assessment phase, participants were required to (a) solve a specific division expression and (b) construct two distinct word problems that accurately modeled that expression.

Participants

The participants were 28 elementary school teachers from a Western U.S. state. They participated in a week-long professional development on Number and Operations. Each participant generated two word problems during the pre-test and two during the post-test, resulting in a total sample of 112 posed problems ($n = 56$ per administration).

Data Collection Tasks

The pre-test task required teachers to generate two distinct word problems for the expression $34 \div 6$. The post-test task required two problems for $48 \div 8$. Between the two administrations, teachers participated in a professional development (PD) intervention. Grounded in the construct of *Mathematical Knowledge for Teaching* (Ball et al., 2008), this instruction focused on:

- Division Models: Distinguishing between partitive and measurement (quotative) division.
- Multiplicative Structures: Identifying various semantic frameworks, such as multiplicative comparison and Cartesian products (Greer, 1992).
- Quality Indicators: Applying features of high-quality word problems, emphasizing linguistic clarity and the explicit requirement of equal grouping.

Data Analysis

All posed problems were transcribed and systematically coded using a three-dimensional analytic framework developed from established research on multiplicative thinking (Carpenter et al., 1999; Verschaffel et al., 2000):

1. Division Type: Categorized as either partitive or measurement.
2. Multiplicative Structure: Classified into four types: equal groups, multiplicative comparison, Cartesian product, or area/products of measures.
3. Qualitative Features:
   - Clarity: Evaluated on a three-point scale (not clear, weak clarity, or good clarity).
   - Equal Grouping: Coded as either explicitly equal or not explicitly equal.
   - Contextual Themes: Categorized by the thematic content used to represent the dividend and divisor (e.g., food, discrete objects, living creatures, or abstract quantities).

To ensure the rigor of the findings, a subset of the problems was double-coded by the research team. Inter-rater agreement was calculated, and any discrepancies were resolved through consensus to ensure coding reliability (Silver & Cai, 1996).

Results

Division Types: Partitive vs. Measurement

The distribution of division models shifted notably following the professional development intervention. On the pre-test, participants primarily utilized partitive division over measurement division. By the post-test, the frequency of measurement division increased substantially while partitive models decreased to 31%. Although the partitive model remained the dominant choice, these results indicate that instruction effectively broadened teachers' capacity to construct measurement-based scenarios

Table 2: Frequencies of Posed Problems by Division Type

Division Type	Pre-test (34÷6)	Post-test (48÷8)	Total
Measurement (Quotative)	17	25	42
Partitive (Sharing)	39	31	70
Total Posed Problems	56	56	112

Note. N=28 teachers; two problems per teacher

Qualitative notes provided by participants revealed a shift in perceived difficulty. Pre-test reflections suggested a preference for partitive division due to the familiarity of "sharing" actions. Conversely, post-test reflections indicated that some teachers found measurement division more accessible because it naturally supports strategies like repeated subtraction or determining how many units "fit" into a total.

Multiplicative Structures

Analysis of the structural framing revealed a lack of diversity in multiplicative contexts. Across both administrations, participants exclusively utilized equal-groups structures. Within this category, fair-sharing contexts predominated, with a smaller subset representing rates or measures. Notably, no problems were coded as multiplicative comparison, Cartesian product, or

area models. This suggests that teachers may perceive equal-grouping as the only viable or accessible structure for elementary division instruction.

Problem Quality

Clarity, Explicit Grouping, and Context: Instruction appeared to have a significant impact on the mathematical precision of the posed problems. As shown in Table 3, the proportion of problems characterized by "Good Clarity" rose from 33.9% on the pre-test to 53.5% on the post-test.

Table 3: Clarity and Equal-Grouping Codes for Posed Problems

Code	Pre-test f(%)	Post-test f(%)	Description
Not clear	10 (17.9%)	7 (12.5%)	Ambiguous or unsolvable wording
Weak clarity	27 (48.2%)	19 (33.9%)	Mostly solvable but somewhat confusing
Good clarity	19 (33.9%)	30 (53.5%)	Clear quantities and explicit unknown
Equal grouping	27 (48.2%) equal; 29 (51.8%) not explicit	36 (64.2%) equal; 20 (35.7%) not explicit	Whether problems explicitly stated equal sharing/grouping

Note. N = 56 posed problems per test administration.

From pre- to post-test, the proportion of problems coded as good clarity increased from 33.9% to 53.5%, while not-clear problems decreased. Similarly, the proportion of problems that explicitly indicated equal grouping increased from 48.2% to 64.2%. These findings indicate that instruction supported teachers in writing more mathematically precise division word problems.

Contextual Themes

Table 4 details the thematic choices for the dividend and divisor. Teachers demonstrated a heavy reliance on a narrow set of familiar contexts.

Table 4: Context Themes Used to Represent Dividend and Divisor Across All Posed Problems

Component	Theme	f (%)	Examples
Dividend	Food	44 (39.2%)	brownies, cookies, pizzas, candies, cupcakes
	Objects	44 (39.2%)	baskets, cups/containers, marbles, stickers, tables, bags
	Living creatures	22 (19.6%)	students, cows, friends, groups, people
	Abstract	2 (1.7%)	(rare)
Divisor	Food	1 (0.8%)	(rare)
	Objects	46 (41.0%)	bags, baskets, bowls, pieces, plates, vans
	Living creatures	62 (55.3%)	friends, children, people, groups, students, teams
	Abstract	3 (2.6%)	days, hours, rows, room area

Note. Percentages are based on N = 112 posed problems across both test administrations.

Teachers most frequently used food and object contexts to represent the dividend, and living-creature contexts (e.g., friends, students, teams) to represent the divisor. Abstract contexts were rare. Overall, the results suggest a reliance on a limited set of familiar contexts, consistent with prior observations that food-sharing scenarios are common in posed division problems.

Discussion

This study investigated elementary teachers' conceptual understanding through the dual lenses of problem posing and solving. The findings provide a critical look at the "default" schemas teachers bring to instruction and the extent to which these boundaries are malleable.

The Partitive Bias and Malleability of Practice

The significant pre-test preference for partitive division suggests a deeply rooted cognitive association between division and the physical act of sharing, as identified by Fischbein et al. (1985). However, the post-test shift indicates that teachers' pedagogical repertoires can be expanded through explicit instruction. This suggests that the "partitive bias" is not a lack of capability, but perhaps a lack of exposure to the quotative (measurement) model in professional training.

Structural Constraints

The absolute absence of non-equal-groups structures (e.g., Cartesian products or area models) is a striking finding. While equal-groups contexts are a vital entry point, the failure to utilize varied multiplicative structures may limit students' ability to generalize division to higher-level domains (Vergnaud, 1983). This suggests that teachers may view these alternative structures as inaccessible for elementary-grade contexts, or they may lack the SCK required to model them (Ball et al., 2008).

Improvements in Semantic Precision

The marked improvement in linguistic clarity and explicit equal grouping highlights a crucial intersection between language and mathematics. On the pre-test, many problems were "underdetermined", meaning the situation was too ambiguous to guarantee a single mathematical path. The post-test results suggest that when educators are trained to define the unknown and specify constraints, they produce more coherent and instructionally effective tasks (Silver, 1994).

Implications for Teacher Education

- Expansion of Multiplicative Repertoires: PD should move beyond the "fair sharing" archetype to include non-equal-groups contexts, such as rates and area models, to support students' flexible reasoning.
- Precision as a Professional Skill: PD should treat problem posing as a rigorous skill. Focusing on semantic precision helps teachers avoid "cliché" tasks that lack mathematical depth (Osana & Pelczer, 2015).
- Contextual Variation: Instructors should be encouraged to move beyond food-and-living-creature contexts, incorporating abstract and scientific measures to better prepare students for the varied applications of division.

In conclusion, this study highlights both the initial predominance of partitive, equal-groups models in teachers' posed division problems and the malleability of that preference. Following targeted professional development, teachers demonstrated increased use of measurement division and greater mathematical precision in the construction of their tasks. These findings suggest that intentional professional learning can broaden teachers' conceptual repertoires and strengthen their capacity to design mathematically rigorous instructional problems.

This study examines comparison as a central practice in proportional reasoning and explores how foregrounding comparison in professional development (PD) shapes teachers' reasoning with respect to invariance and generalizations. Data were collected from two PD offerings. Findings show that comparison can be used to identify invariant properties and to advance generalizations across dimensions, functioning both as a conceptual foundation for other concepts such as ratio and as an instructional tool for sense making. Findings further show that teachers predominantly engaged in between-objects comparison and tended to rely on empirical reasoning, suggesting that PD should explicitly support multiple forms of comparison, attention to invariant relationships, and precision in comparative language to foster structural generalization. Implications for teacher education and professional development are discussed.

Keywords: Curriculum and Instruction, Teacher Knowledge, Proportional Reasoning and Similarity, Variance and Invariance

Purpose and Background

Proportional reasoning is a foundational concept essential for a learner's progression beyond elementary mathematics (Lamon 2007), yet it is widely recognized as challenging for both students (Karplus et al., 1983; Lamon, 2007; Thompson & Saldanha, 2003) and teachers (Jacobson et al., 2018; Modestou & Gagatsis, 2010). Robust understanding of proportional reasoning involves multiplicative reasoning about relationships between quantities, not merely solving tasks for an unknown in equivalent fractions (Lamon, 2007; Weiland et al., 2019, 2021).

Variance and invariance are fundamental concepts for mathematical reasoning (Nagar et al., 2022a, 2022b), and teachers' ability to identify invariant properties is essential to development of robust understanding of mathematical concepts. Despite the importance of invariance in proportional reasoning, there is little research available considering these domains (Nagar et al., 2025), especially in working with digital representations.

Prior research suggests that proportional reasoning depends on coordinating quantities across and within measure spaces (Lamon, 1995; Thompson & Thompson, 1996). Teachers often show preferences for comparing using only within or only between measure spaces (Orrill et al., 2010), which influences how scale factors and constant relationships are recognized. Studies on double number lines further show that difficulties arise not from lack of procedural knowledge but from challenges coordinating quantities and identifying what stays equivalent across relationships (Orrill & Brown, 2012). Similarly, research on proportional tasks presented visually indicates that multiplicative comparison alone is insufficient when dimensional shifts occur, e.g. when reasoning shifts from length to area (Orrill & Burke, 2013).

Building on this work, we hypothesize that comparison is a foundational mathematical practice through which invariant relationships can become discernible and generalizations can be constructed. The present study examines how comparison operates within professional development (PD) contexts and how it both supports and destabilizes teachers' reasoning about proportional situations. This study explores the following research question: *how do in-service teachers (grades 3–9) use comparison to identify invariance and develop generalization about proportional reasoning using digital representations in two PD workshops?*

Theoretical Framework

Knowledge in Pieces

We view teacher knowledge through the lens of Knowledge in Pieces (KiP; diSessa et al., 2016), which asserts knowledge is comprised of fine-grained understandings (i.e., knowledge resources) that work in interconnected ways in any given situation. Learning is considered the development of new knowledge resources, the refinement of existing resources, and/or the creation of connections between and among knowledge resources. Connections are particularly important because they control flexibility in a person's ability to invoke a wide variety of knowledge resources in a given situation. KiP is powerful for characterizing teachers' knowledge because, rather than trying to quantify the amount of knowledge a teacher may or may not have, KiP allows a fine-grained analysis of the knowledge invoked in a given situation.

Our use of the KiP framework emphasizes the process of thinking, not only the end result of such a process. Accordingly, we value the process of comparing elements in a task, identifying invariance, attempting to generalize, checking conjectures, and making connections among knowledge resources. These processes can help us study how teachers connect and use their knowledge when unpacking a task.

Invariance and Invariant Feature of Change

We define invariance by referring to properties that remain unaltered when a transformation is applied or described (Hadas et al., 2000; Laborde, 2005; Leung et al., 2013; Nagar et al., 2022a). In the context of proportional reasoning, we referred to mathematical transformations such as scaling up, scaling down, inverting, resizing, and so on. For instance, one might consider a cookie recipe with two cups of flour and one cup of sugar. If you double the recipe, the amounts change, but the part-to-part ratio, *2:1*, remains the same. This ratio has an invariant property, staying constant when the recipe is scaled up or down.

Nagar et al. (2024) found teachers describe an invariant property as something that changes, but a feature of that change remains constant (e.g., always decreasing or increasing, always doubling, etc). For instance, when doubling ingredients in a recipe, one might observe that each amount changes; however, the *feature of change remains the same,* everything is "doubled."

In the current work, we examine how comparison invokes knowledge resources related to invariant properties and the connections between these resources teachers made. This is important as making connections between knowledge resources suggests they are more readily drawn upon across a wide range of situations (Brown et al., 2020).

Generalization

We draw on Mason et al.'s (2010) definition of generalization as the process of moving from observing a few instances to extrapolating a wider class of cases. In Mason et al.'s (2010) work, two types of generalizations were identified: *empirical* and *structural*. Empirical generalization occurs when one looks at several instances to identify what is the same about them in order to form a conjecture (Mason et al., 2010). Empirical generalization does not guarantee the truth of that conjecture. Structural generalization occurs when one recognizes relationships and patterns

that "has to be justified by reference to underlying structure" (p. 232). Structural generalization is a more reliable form of generalization because it goes beyond observation to understanding how the structure itself operates. One of our goals in the current work is to examine empirical and structural generalizations and how participants used them as part of reasoning.

Comparison

We define *comparison* as a mathematical practice through which quantities are coordinated within or across measure spaces to establish relationships among attributes of a situation. Comparison involves selecting elements or quantities, determining correspondences among them, and attending to invariance. Research suggests that proportional reasoning depends on coordinating quantities across and within measure spaces (Lamon, 1995; Thompson & Thompson, 1996). Yet the role of comparison often remains implicit. Research has shown that attending to measure space is important in making comparisons that might appear proportional, but are not, such as comparing length to area (Orrill & Burke, 2013), highlighting the importance of a deep understanding of structures underlying comparisons. We therefore hypothesize that comparison can function as a process through which invariants can be identified, relationships formed, and structural generalizations can be constructed in proportional situations.

Data Sources and Methods

This study is part of a larger project exploring teacher knowledge of rational numbers. The 30-hour PD (five consecutive days) focused on key mathematical ideas such as referent units, invariance, covariation, and quantity. Teachers worked in small groups on tasks, followed by whole-group discussions. We analyzed two PD offerings in the Northeastern U.S. The first had 31 grades 3–9 math teachers in an urban district (five male, twenty-six female). Twenty-five identified as White, six Black, Hispanic, Native American, or multiracial. Teaching experience ranged from one to 30 years (mean = 9.4), and 21 had at least a Master's. The second had 15 grades 2–11 teachers (three male, twelve female), with one Asian, one Black, and the rest White. Experience ranged from three to 26 years (mean = 10.8), and eleven had a Master's or higher.

We considered one group from each setting, selected for being talkative, working on a task focused on comparisons (Figure 1). Group A included five elementary teachers and the second author as the facilitator. Group B included five middle graders special education teachers and a facilitator (not an author). Both facilitators used the same PD plan to maintain consistency. The Kitties Task, used on Day 5, involved a dynamic tool that scaled the two kitties proportionally (within a kitty and across kitties) in length and width (Figure 1b). Also, both kitties could be moved around in space. Participants explored the relations as shown in Figure 1a. We focused on this dynamic task since Brown et al. (2020) showed that using those in PD can support teachers in developing connections to make their knowledge resources more accessible.

We focused our data analysis on verbatim transcripts of each group's conversations as they solved the task, supplemented with descriptions of participants' observable actions from the video recordings. This resulted in detailed records of what participants said and did while exploring the Kitties task. Our analysis proceeded in two coding cycles: *descriptive coding,* followed by a *pattern coding* (Miles et al., 2014). Two team members led the descriptive coding, identifying references to comparisons, invariants, and generalizations as related to our coding scheme (Table 1). In the second cycle, we grouped utterances by analytic category and not chronologically, to determine what was compared, whether invariance was articulated, whether reasoning was empirical or structural, including any generalization. Finally, the full research team met to review, discuss, and refine codes, and to identify patterns.

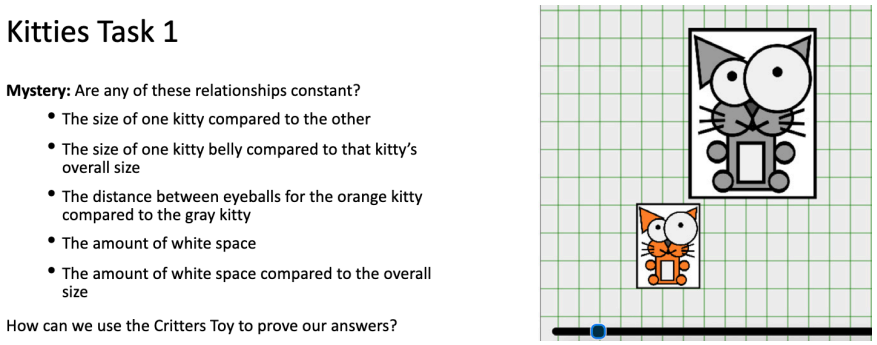

Figure 1: Kitties Task – (a) Task Posed to Participants About the Kitties, (b) Screenshot of the Digital Representation Tool

Table 1: Coding Scheme

Code		Description
CB	Comparison between two objects (one set)	Refers to participants looking at how quantities are related (compared) to each other between two objects (one set of objects)
CW	Comparison within an object	Comparing quantities within an object (e.g., comparing height and width of a kitty)
CS	Comparison across sets of objects	Indicates that participants are comparing quantities using sets of objects, i.e., comparing multiple instances of the objects (more than one set)
IP	Invariant Property	Refers to an invariant property that is maintained (properties that remain unaltered when a transformation is applied or described). Records the property.
EG	Empirical Generalization	Considering invariance to form a conjecture related to the situation by discerning "sameness." We coded any attempt for a conjecture, even if the wasn't established
SG	Structural Generalization	Indicates that participants identified relationships or patterns that are invariance and can be explained by reference to underlying structure. This was more reliable than EG because it suggests an understanding of how the structure operates
ES	Example Spaces	Indicates if participants generated one or more examples of objects describes them
JS	Justification	Explanations and justifications provided as part of the reasoning.
AP	Approximation vs Precision	A - Indicates that participants used approximation to reason proportionally P - indicates that participants used exact measurements to reason proportionally.

We focused our data analysis on verbatim transcripts of each group's conversations as they solved the task, supplemented with descriptions of participants' observable actions from the video recordings. This resulted in detailed records of what participants said and did while exploring the Kitties task. Our analysis proceeded in two coding cycles: *descriptive coding,* followed by a *pattern coding* (Miles et al., 2014). Two team members led the descriptive coding, identifying references to comparisons, invariants, and generalizations as related to our coding scheme (Table 1). In the second cycle, we grouped utterances by analytic category and not chronologically, to determine what was compared, whether invariance was articulated, whether reasoning was empirical or structural, including any generalization. Finally, the full research team met to review, discuss, and refine codes, and to identify patterns.

Results

In what follows, we present findings related to participants' use of comparison across the two PD contexts. We first describe how comparison emerged in participants' work with digital representations and examine its function in their reasoning. We then highlight the invariant properties and relationships participants identified while engaging in comparative reasoning. Next, we present participants' reasoning processes and the types of generalizations articulated as they drew on comparison. Finally, we illustrate how comparison can serve as a source of productive destabilization through a specific case example.

Comparison as a Central Mathematical Activity in the Kitties Task

Table 2 summarizes the comparisons identified, including sample utterances, the invariant properties discussed, and the generalizations that emerged. Teachers engaged in several types of comparison: between the two kitties' overall size, between the kitties' linear features, within a single kitty, and across sets of kitties (i.e., involving more than one pair).

Table 2: Comparison, Invariance, and Generalization

Comparison Type	Evidence - Sample Utterances	Invariant Properties / Relationships	Generalization Type
		Comparison Between – Size	
Group A	**"**Four small kitties within [gray kitty]"; "4 to 1"; "Gray is ¼ of orange"; "1 belly to 4 bellies"; "size orange to gray is constant"	• The size of one kitty compared to the other stays constant • Ratio remains constant	Empirical and observational – within the task
Group B	"Half the size"; "orange lengths are [half the size]"	• Kitties' shapes always remain a square • Orange's lengths always half of gray	
		Comparison Between - Linear Features	
Group A	"Each side is times 2"; "Distance between eyeballs 3:1"; "Distance between the pupils 2:1"; "proportion of length and width is constat between the two cats"	• All sides are multiplied by 2 • Distance between eyeballs remains the same (2 to 1)	Mostly Empirical. Participants struggled comparing the distance between the eyeballs and tried to approximate it.
Group B	"4 to 1.5"; "distance stays 2 to 1, 'cause there's still similar figures"; "all ratios stay same."	• Figures remain similar • Distance stays 2 to 1 ratio • If figures stay similar, distance stays 2:1	One structural claim made in Group B (similar figure)
		Comparison Within - One Kitty	
Group A	"Belly scaling at same rate"; "Amount of white space compared to overall size is constant"	• Belly is changing at same rate • Amount of white space stays constant • Belly to whole remain a constant ratio	Empirical and based on inspection. Participants struggled comparing different objects within one kitty
Group B	"Fractions simplify to ¼"; "The amount of white space compared to the overall size is constantly half"	• Inside of kitties remains similar bellies/figures • Fractions stay ¼ • If fractions stay the same, objects are proportional • The comparison of white space to overall kitty stays constant and remains 1/2	

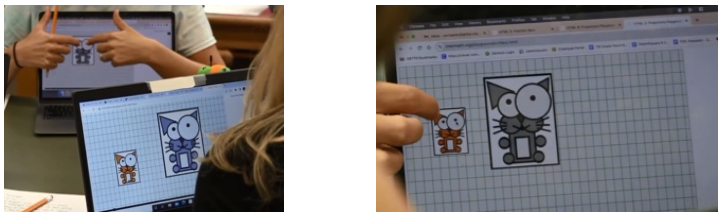
	Comparison across Sets		
Group B	"Counting by 2s going up adding one whole box"; "Both [bellies in sets of examples] about 1/4 of the frame"; "length and width ¼"; "area is ¼ of the frame"; "16 next because doubling dimensions"	• As linear dimensions keep going up by 2 the distance keeps adding 1 • If you change the size going up by 2, the distance keeps adding 1 • Belly stays ¼ of the frame in both sets • Length/width remains same • Belly area remains ¼ of the frame • doubling the dimensions	Empirical. Looked at both dimensions: linear length and width and area. Expressed tension between additive vs multiplicative relationships. Additive reasoning

Comparison between sizes. Both groups used comparisons between kitties to reason about how their sizes compared. In Group A, Glinda began her exploration by setting the gray kitty to 8×8 and orange kitty to 4×4. She then positioned the orange kitty on top of the gray kitty and explained that "four of these small kitties [fit] within," indicating that she was determining how many orange kitties could fit inside the gray one. Others in Group A discussed size comparisons in similar ways (Table 2). In contrast, participants in Group B compared the kitties' sizes by referring explicitly to length and width, concluding that one kitty was half the size of the other.

Elena: The size of one kitty compared to the size of the other. So it's half the size, right?
Dale: Yours was five.
Elena: And the other one was ten. And you have four and eight, right?
Dale: Yeah, yeah, so. So the length. Orange one is half.
Elena: Orange = ½ gray one and *w* [wrote on paper, suggesting *l* = length and *w* = width]

In making comparisons between the kitties' sizes, participants identified several invariant properties, such as the ratio remained constant and orange's kitty's lengths remained half of the gray kitty. However, identifying invariant properties did not guarantee correctness. For example, claiming the Kitties' shapes always remained square, despite the figures being rectangles. Participants relied on empirical generalizations and did not mention invariant relationships between constant properties, and their generalizations tied to the task context.

Comparison between linear features. When comparing linear features like the kitties' eyeball distances, both groups focused on specific features and were more explicit than when discussing size, with Group A approximating the distances. Wanda, Mara and Pepper initially agreed the relationship was "3 to 1" (Wanda). Glinda questioned this since earlier comparison of sizes suggested a 1 to 4. After Mara resized the kitties (orange approximately 3×3 vs gray 6×6), the group reconsidered and concluded the distance comparison was "1 to 2" (Mara).



Group B struggled to quantify this relationship even using comparisons across sets (described below). They were unable to determine whether the relationship was constant until later on in the whole group discussion Charlotte used structural knowledge suggesting that the eyeball distance "stays 2 to 1 'cause there's still similar figures, so all the ratios stay the same."

Across these linear comparisons, participants identified invariant properties (Table 2). Glinda in Group A noted although sides change, they are all multiplied by two. Generalizations remained largely empirical, except for one structural claim made by Charlotte who connected two invariant properties to suggest that similarity guarantees a constant ratio of 2:1 between linear features.

Comparison within one kitty. Participants in both groups compared elements within a single kitty but struggled to quantify those relationships. Group A saw the belly was changing relatively to the overall kitty and how that impacted the amount of white space. Glinda suggested that the "belly of the cat is scaling up … at the same rate as the entire cat" and she proposed

finding "the ratio instead of just say[ing] it's constant." Wanda and Pepper argued determining the ratio was difficult because they could not determine how many bellies fit within the figure.

In Group B, participants found it difficult to compare "the frame of the belly to the frame of the cat" (Dale). Elena described the relationship as proportional because they were "multiplying," and Dale proposed making "a chart of all different lengths" to demonstrate that "all fractions … come out to a ¼". However, they appeared to confuse the dimensions. Dale referred to linear measurements while reasoning about the belly which is two dimensions (2D). This confusion reappeared when Elena suggested that the amount of white space would remain "constantly half," extending her previous linear comparison results to an area-based relationship. The invariant properties were identified and the reasoning was based on empirical generalization.

(a) (b)

Figure 2: Dale and Elena's Sets of Kitties Comparison – (a) Dale and Elena Comparing Across Sets, (b) Dale Points to the Eye of the Orange Kitty

Comparison across sets of kitties. The least common comparison involved sets of kitties. Several Group B participants used this comparison relying on two sets of kitties when examining the eyeball distances (Figure 2), and the belly to frame relationships. When comparing eyeball distances, they relied on additive reasoning rather than multiplicative. For example, Dale and Elena described how increasing the size of the kitties "by 2s," added "one whole box" to the eyeball distance. Dale and Elena struggled to determine whether the relationship was invariant and how to quantify it. Later, using their set of kitties, they examined belly to frame comparison and despite difficulties approximating measurements, they concluded that "the belly remains ¼ of the frame" (Dale). Although participants identified invariant properties, they exhibited a tension between additive and multiplicative reasoning. Their attempt to generalize was again empirical, and the additive reasoning led them to propose an invalid invariant relationship.

Destabilization through Comparison

The results suggest that comparison can destabilize teachers' reasoning in productive ways. In Group B, comparison exposed underlying assumptions and led to an overgeneralization shared by both participants and the facilitator:

Facilitator:	What are you noticing about the kitties?
Raymond:	The black and white [gray] is always double the size of the color [orange].
Facilitator:	What do you mean by size?
Raymond:	Length and width.
Tina:	In high school you're teaching them to put one side length over another side length. But when you do area, it's double, and when you do volume you have to triple it.

Facilitator:	Doubled, yes, because the area is a two-dimensional quantity, and then the length and width are linear quantities, and so the relationship winds up being different.
Amira:	But is it more like dilation then? I mean isn't it what we do in dilation.
Raymond:	No, she's talking more so about the area. Yeah, the area, the whole picture, in comparison to this. So it's, we're saying like it's twice as big, but we're referring to the length, but the area, whatever it doubles.

Early in the exploration, participants described the gray kitty as always being double the size of the orange kitty, referring to length and width. As discussion shifted toward area, both participants and facilitator extended this comparison without attending to the structural change involved in moving from linear to 2D quantities. The facilitator explained that area was "doubled" rather than emphasizing that area now changes by the square of the linear scale factor. This language use obscured the dimensional structure of the situation and illustrates how comparison can generate a conceptual tension rather than clarity.

Discussion and Conclusions

In this study, we found comparison can function as a central practice in proportional reasoning that, when foregrounded in PD, can both destabilize and advance teachers' understanding. Comparison supported teachers in identifying invariance and moving toward generalization. We saw comparison as a mathematical concept that helps define other concepts such as ratio and as an instructional tool to advance mathematical exploration and reasoning.

We identified three categories of comparisons used by teachers: comparisons between objects, within a single object, and across sets of objects, with comparisons between objects being dominant. Teachers used comparisons to identify constant relationships across dimensions, quantify ratios, search for patterns, and attempt justification and generalization. These findings suggest that PD may benefit from explicitly foregrounding comparison and supporting teachers to engage in multiple forms of comparison, rather than relying on between objects comparisons.

In both groups, comparison played a critical role to support the identification of invariant properties that enabled teachers to unpack the tasks and advance sense making. We posit that comparison can be a gateway to invariance. This finding is significant given prior work showing teachers do not typically introduce invariance spontaneously (Nagar et al., 2022a). While participants identified invariants, they less frequently articulated logical (if-then) relationships among them. When such relationships were proposed, they reflected attempts to move beyond empirical observation toward structural generalization and reasoning, for example, recognizing that if figures are similar, then that ensures the ratio between distances (e.g., between eyeballs) must remain constant. These results suggest PD should encourage teachers to examine logical relationships among invariants, as they appear critical for understanding proportional structure.

Notably, the teachers in our study rarely compared quantities within a single object or across sets of objects. Such comparisons may be especially important for reasoning about similarity and proportional structure within figures as well as for testing generalizations. We saw that comparisons across sets, particularly when paired with attention to invariance, appeared to support pattern recognition and opportunities for generalization. Future research should examine how PD can better support teachers to engage in within object and across sets comparisons.

Generalizations observed in this study were predominantly empirical rather than structural. Teachers' reasoning relied largely on observed cases and offered intuitive conjectures, with limited justification. We posit that shifting teachers' focus to invariant relationships may help

promote structural generalization. Future research should further investigate how teachers can be supported in moving from empirical to structural generalization.

Importantly, we saw comparison can destabilize teachers' reasoning in productive ways. Comparison can expose hidden assumptions, confusion about units, reliance on approximation, and difficulty coordinating multiplicative relationships. For example, both groups struggled to reason about the distances between the kitties' eyeballs, relying on empirical reasoning, while Group B also slipped into using additive reasoning instead of multiplicative reasoning which invoked an incorrect response. Such moments represent valuable opportunities for teachers in PD to surface and examine the multiplicative nature of proportional reasoning and similarity.

Finally, discussions in Group B revealed a productive tension when reasoning shifted from linear relationships to area relationships, particularly as the facilitator repeatedly invoked the language of *doubling* rather than *squaring*. This suggests a conceptual tension: imprecise language obscured the dimensional structure of the situation, making it difficult to determine whether teachers' reasoning reflected minor verbal imprecision or deeper misunderstandings about invariant relationships across dimensions. We therefore argue PD should explicitly attend to the precision of comparative language and intentionally support teachers in reorienting comparisons when dimensional shifts occur, helping participants move from empirical observations toward structural generalization. Rather than avoiding confusion, PD can intentionally design moments in which comparison surfaces conceptual tension, creating opportunities for deeper structural understanding and generalization.

ARTICULATING INSTRUCTORS' KNOWLEDGE FOR TEACHING MATHEMATICS IN AND FOR ENGINEERING

Scholars have documented a persistent disconnect between college math as taught in math departments and as used in disciplines such as engineering. Drawing on a broader study investigating mathematical knowledge for teaching that supports students' application of math in engineering contexts, we focus on the question: What knowledge is entailed in the instructional work of interpreting students' use of math in an engineering context? We use a case study of a math instructor analyzing an engineering student's reasoning on a Calculus task to argue that such instructional work requires a "dually bifocal lens," meaning that they: (1) have a conscious awareness of both disciplinary lenses and (2) notice the perspective(s) that a learner takes; and ultimately, develop a repertoire of techniques to shift learners' back and forth between lenses.

Keywords: Mathematical Knowledge for Teaching, Calculus, Undergraduate Education

Introduction

Our work addresses a key disconnect in the mathematical education of engineers: the lived separation between engineering practice and mathematics course experiences. As undergraduates, engineers report experiencing conflict between mathematics as practiced in mathematics coursework and as applied in engineering courses (e.g., Alpers, 2017; Bingolbali et al., 2007; Jablonka & Bergsten, 2023). As professionals, engineers report viewing their undergraduate mathematics experiences as irrelevant to their work (Quéré, 2017; Härterich et al., 2012; Pearson, 1991). As these studies indicate, the problem is not the inherent abilities of students to succeed in coursework, but a perceptual disconnect between math as it is *taught* and engineering as it is learned. We report an effort to address this disconnect through the study of the *instructional knowledge* required to help undergraduate students learn to apply mathematics.

The purpose of this paper is to examine disciplinary knowledge for teaching mathematics service courses whose students largely consist of STEM majors outside of mathematics. The data discussed in this paper comes from a larger study whose overarching agenda is to characterize the mathematical knowledge for teaching that allows students to learn to apply mathematics in engineering contexts. Here, we focus on the research question: What knowledge is entailed in the instructional work of interpreting students' use of mathematics in an engineering context? We articulate such knowledge in the context of a case study, where we focus on a mathematics instructor, Alaina, as she examines an engineering graduate's thinking on a Calculus task. This case allows for analytic generalization (Yin, 2018) into an aspect of instruction that is needed to address the problem of disciplinary disconnect. We use collective professional examination of the video records and artifacts of this case to articulate the mathematical knowledge entailed in instructional work (Ball et al., 2014). We then problematize the implementation of such knowledge in practice under the current disciplinary constraints of Calculus as a service course.

In the United States where this study is based, introductory (differential and integral) Calculus courses are considered first-year university courses and serve as prerequisites for a variety of STEM coursework. For this project, we choose engineering as our application domain, and first year Calculus as our instructional domain, due to the (a) unique role of Calculus in our context as both a "scaffold" and "filter" (Biza et al., 2022) for STEM degrees, and thus its pronounced impact on first year undergraduate students; (b) need for Calculus concepts across engineering subdisciplines (e.g., Engineering Accreditation Commission, 2025) and; (c) opportunity to build on a substantial existing base of literature on the mathematical education of engineers (see Alpers, 2020 for a review).

The main result of our work is a conceptual framework, which we term a *dually bifocal perspective.* We use the term "bifocal" to reference Ball's (1990) observation that teaching inherently requires seeing near and far, and we introduce "dually bifocal" to refer to the disciplines of mathematics and engineering. We build on the premise that successful learning of mathematics in and for engineering requires teaching students to draw on two partially overlapping disciplinary lenses-a mathematical lens focused on generalizability and internal structure, and a contextual lens focused on real-world constraints and practicality. We then use our case toward the following articulation: *Knowledge for teaching mathematics in and for engineering requires conscious awareness of both disciplinary lenses, noticing the perspective(s) that a learner takes, and ultimately, a capacity to shift learners' back and forth between disciplinary dispositions.* While our case focuses on Calculus and engineering, we believe that our characterization may extend to mathematics in and for other client disciplines.

Literature Review

The calculus sequence exerts significant influence over engineering students' academic preparation for later coursework and their perception of mathematics and its relationship to engineering (Gardner et al., 2007; Middleton et al., 2014; Van Dyken et al., 2015; O'Connor et al., 2015; Biza et al., 2022). The link between engineering contexts and mathematics learned in these first- and second-year math courses is often unclear, to both students and engineering faculty, as the following literature shows. Students report a lack of awareness of the substantial role that prerequisite mathematics may take in engineering coursework (Harris et al., 2015); as well as skepticism about the relevance of theoretical mathematics in their future careers (Flegg et al., 2012; Wood et al., 2008); Engineering faculty state that beginning engineering students often struggle to connect first and second-year mathematics concepts to their introductory engineering courses without significant support (Faulkner et al., 2019; Engelbrecht et al., 2017).

Previous work to address this problem has historically focused on departmental leadership and curricular development (e.g., European Society for Engineering Education [SEFI], 2013; Smith et al., 2021) in advanced courses such as linear algebra, differential equations, or complex variables (e.g., Alpers, 2001; Barquero et al., 2013; Hjalmarson et al., 2023; Härterich et al., 2012; Peters, 2023; Rønning, 2023; Schmidt & Winsløw, 2021). For instance, Schmidt and Winsløw (2021) reflected on 20 years of task design for a mathematics course addressing linear algebra, differential equations, and differentiable vector fields. They created in-depth assignments (some with 5 pages of data and 18 pages of student-facing text) in contexts such as Halbach magnet arrays, home heating, and red blood cells. Another common approach is to infuse examples throughout a course, even if the students do not engage with the examples in depth. For instance, Kerrigan and Prendergast (2021) solicited examples from engineering faculty for a flipped precalculus course. Burrill et al. (2023) reported a similar effort to redesign linear algebra, with the effect that the "students appreciated the content much more and

enrollment in [this course, offered by the Department of Mathematics] grew vigorously while that of the analogous class from the school of engineering dropped precipitously" (p. 800). Finally, other more resource-intensive approaches include team teaching (e.g., Quintanilla et al., 2007), coordinated mathematics and engineering courses (e.g., Laoulache et al., 2001; Lowery et al., 2010; Schroeder & Carpenter, 1999), and specialized sections for engineering majors (e.g., Horwitz & Ebrahimpour, 2002; Sathianathan et al., 1999).

These efforts are effective, but may not translate easily into instructional knowledge beyond the immediate faculty involved. Indeed, there is ample evidence that excellent curricular materials are not enough; instructors must also have the personal resources and sufficient pedagogical knowledge to enact curricular materials in the intended manner (Cohen, 1990; Ganter, 1999; Stein et al., 2007). However, there is very little existing literature describing the kind of pedagogical knowledge required to effectively teach mathematics in and for engineering, and thus minimal understanding of how to support instructors in effectively mending the perceptual disconnect between these disciplines. In their systematic reviews of knowledge for teaching at the undergraduate level, Andrews et al. (2022) and Sarkar et al. (2024) independently found only one article addressing engineering: Viiri (2003), who only argued that instructor knowledge of students' conceptions of engineering topics was an aspect of pedagogical content knowledge.

There is thus room for innovation in this area, especially in lower-division courses including Calculus, where improving retention will have the most impact due to the larger pool of students. Instructors' knowledge shapes their teaching, and thus students' learning (e.g., Baumert et al., 2010; Kraft et al., 2024; Stein et al., 2007). Hence, if we, as a field, better understand how instructors can convey and notice the disciplinary interactions between mathematics and engineering, we might then be able to help students connect these disciplines in their coursework. We thus focus on instruction, and the knowledge entailed in instruction, to advance existing work.

Conceptual Perspective

We define *mathematical knowledge in and for teaching (MKT)* as the mathematical skills, dispositions, and reasoning entailed in and developed through the recurrent work of teaching (Ball et al., 2008; Rowland & Ruthven, 2011; Thompson & Thompson, 1996). In developing MKT, teachers may iteratively synthesize interpretations of students' thinking with their personal understandings (Silverman & Thompson, 2008). When a subject intersects with two disciplines, knowledge for teaching must then draw on discourse and interactions in both disciplines.

We use the terms *mathematics in and for engineering (MEng)* and *teaching mathematics in and for engineering* in analogy to MKT. Just as there is specialized mathematical use entailed in teaching, there is also specialized mathematical use in engineering (Alpers, 2010; Kent & Noss, 2002). Moreover, knowledge for teaching mathematics differs from knowledge for doing mathematics as a discipline. In other words, we build the argument that there is a *special domain of knowledge for teaching mathematics in and for engineering*. Instructional representations are needed to ground inquiry into mathematical knowledge for teaching, so that examination can move beyond vague generalities and into articulating features of practice and the knowledge drawn upon in practice (Ball et al., 2014; Boaler et al., 2003). Representations may include video representations of student thinking, through which instructors' engagement may develop MKT (e.g., Philipp et al., 2007). Analogously, examining instructors' analyses of student thinking can help educators refine their perception of instruction (e.g., Amador et al., 2017). When a group of

professionals collectively examines instructional records, the group's interactions can create professional knowledge about teaching (Ball et al., 2014), as we show in this work.

Method

This study used a case to develop theory (Schwandt & Gates, 2018). Rather than seeking to characterize this knowledge comprehensively, we aimed to generate potential features of disciplinary knowledge for teaching mathematics in and for engineering. These findings should be seen offering hypotheses for further inquiry (Yin, 2018). Throughout this report, all participant names provided are pseudonyms.

Data sources for this study were instructional representations (Grossman et al., 2009) designed to support conceptual inquiry into teaching (Ball et al., 2014). Specifically, we inquired into instructional reasoning that draws from the disciplines of mathematics and engineering.

We created instructional representations as follows. First, we recorded two recent graduates of an undergraduate engineering program-Wade and Michael-in a think-aloud protocol (Ericsson & Simon, 1993) on an activity designed to situate calculus constructs in engineering. We refer to this activity as the "Roadway Curve" activity. The activity is based on a standard computation in civil engineering, where the coefficients of a function describing the elevation of a roadway may be derived from surveying data and familiarity with derivatives. We chose recent engineering graduates to maximize the potential for eliciting mathematical reasoning from an undergraduate engineering perspective. Both participants completed the activity successfully.

Second, we recorded two mathematics instructors who were shown excerpts of the engineering graduates' thinking. Both instructors had prior experience teaching calculus. We asked the instructors to complete the Roadway Curve activity themselves, to describe the student thinking they saw in terms of mathematical and outside-of-mathematical reasoning, and to explain how they would respond to this thinking if it had arisen in their calculus class. Instructors were intentionally shown excerpts of reasoning that appeared to us and two engineering faculty to contain moments of maximal contrast with reasoning from the discipline of mathematics. For this report, we present a case study of one instructor, Alaina. This choice is motivated at the start of the results section below.

Analysis proceeded in two phases. The analysis team consisted of the authors and the two engineering faculty. Phase 1 focused on the engineering graduates' reasoning on the Roadway Curve activity while Phase 2 focused on the instructors' responses to the students' reasoning. Phase 1 resulted in the identification of two types of reasoning with mathematics that were accessible to and frequently used by the engineering graduates-reasoning that prioritized contextual details (an "engineering" lens), and reasoning that prioritized generalizability and systematization (a pure "mathematical" lens). Both lenses are discussed in the results.

For the sake of space, we focus on describing analysis from Phase 2, as instructor data is the focus of the current report, and we only discuss one instructor's reasoning. In this phase, we used Ball et al.'s (2014) notion of collective professional examination to examine how instructors interpreted student use of these lenses and discussed their "fit" within the context of calculus instruction. From the instructors' responses, we deliberated about features of instructional knowledge that would promote students' development of mathematics in and for engineering, using our different professional values as a mechanism to make inferences explicit (Akkerman & Bakker, 2011; Schwandt & Gates, 2018). We generated hypotheses about professional practice, through inferences about what was present from the records of the instructor interviews, as well as what may have been absent (Ball et al., 2014; Grossman et al., 2009). This combination of

direct and inferential examination can result in useable knowledge for and about teaching (Kazemi, 2008).

Results

At the time of the study, Alaina was a mathematics graduate student with experience teaching calculus at multiple institutions in the United States. She had no previous experience with engineering coursework, nor with the contextual background (highway design) of the Calculus activity. Alaina's prior teaching experience included recitations intended to elicit and support student thinking on recently introduced topics in lecture, so she had experience in grappling with and responding to student thinking. Because of this, the knowledge involved in her noticing and interpreting students' use of mathematics in an engineering context was more likely to be visible during her interview. Presenting her case here allows us to develop a robust foundation for considering how such knowledge might be cultivated among less experienced graduate student instructors, or instructors with less experience attending to student thinking.

We asked Alaina to engage with Michael's thinking on the activity opening, shown in Figure 1; option (d) is the intended choice. Mathematically, this opening was designed to elicit students' language for differentiability of a function based on its graph. In terms of engineering, option (d) shows a roadway design that adheres to guidelines from the American Association for State Highway and Transportation Officials: two straight segments are connected by a parabola curve so that derivatives at the boundaries are equal. The remainder of the activity examined this parabola segment using first and second derivatives.

Which of the following is the best way to connect two straight segments to make a road?

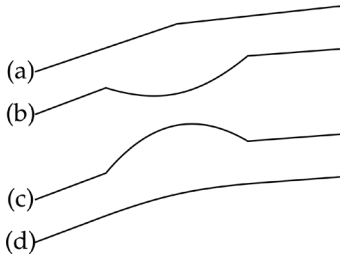

Figure 1: Roadway Curve Activity Opening

As engineering graduate Michael observed, roadway (b) is not desirable because, "This is where children fall off sleds, things come out of the back of your truck, big trucks tip over. We don't like these [roads]." Here, Michael relied on the consideration of additional, reasonable contextual details such as the kinds of transportation that might be done on such roads, to come to a conclusion. We refer to this type of reasoning as reasoning from an *engineering lens*. By an engineering lens, we mean one that sees contextual consequences for "making 'things' that work and making 'things' work better" (Lucas et al., 2014, p. 11). This kind of reasoning was common across Michael and Wade's interviews and is characterized by explicit attention to problem-solving contexts. This includes surmising additional context that may not be necessarily provided by the problem itself to determine which conclusions would be appropriate. Reasoning in this

domain has a goal of considering as many likely realities of a given context as possible to determine the relevant constraints on solution strategies.

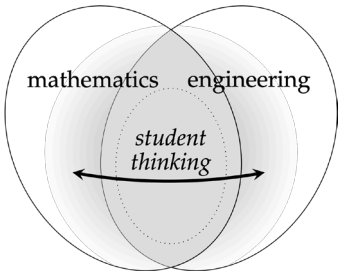
Michael went on to use mathematical language, describing such points as "discontinuities" of the derivative, and noting that two tangent lines placed on either side of each point differ in slope. This is an example of reasoning from a *mathematical lens,* one that focuses on the potential of mathematical concepts to systematize and generalize (Freudenthal, 1968). This kind of reasoning includes intentionally simplifying or backgrounding certain realities of the problem context (e.g., roadway elevation data) and foregrounding other reasoning techniques (e.g. differentiation, analysis of the first derivative, etc.). In this way, Michael provided two types of justification for his claim that (d) was the most sensible choice. We wanted to understand how Alaina would interpret these kinds of reasoning, whether she would recognize these lenses as different, and how she would respond to them in an instructional situation.

When asked to describe Michael's reasoning, she did present evidence that she observed two types of reasoning. Alaina described Michael's initial reasoning with the context as, "thinking about problems in the context of the world, and in the context of how you would actually be driving your car...this is the more intuitive version of what we will probably later formalize [in the class]." Alaina's use of the word "intuitive" here reflects a broader tendency for her to describe reasoning from the engineering lens as a form of "domain expertise" involving experience with the context of the given problem. While she sometimes described this reasoning as "just [using] your opinions," "your feelings," "intuition," and generally being less formal than the reasoning from a mathematical lens, she went on to explain that she would encourage both forms of reasoning in her Calculus course. When asked about the extent to which she would agree with the statement that only some of Michael's reasoning was "really" mathematics, Alaina clarified that she viewed *both* forms of reasoning as falling under a broad spectrum of reasoning with mathematics. As she stated:

> I mean, at some point, [Michael] mentioned discontinuity. I might say, "oh yeah, discontinuity of the derivative." But that's probably the more formalized part of this [reasoning], which is maybe what the other person meant by saying "mathy" is, like, formalized mathy, rather than the understanding that we have of the world, and how things should work, and how things are best. That also is valuable. Because when we're talking about real-world problems, we need domain expertise. That's also valuable.

Here, Alaina's characterization of Michael's work as demonstrating an understanding of how "things should work" and "how things are best" indicates that she recognizes, in some way, hallmarks of mathematical reasoning as interpreted from an engineering lens.

We were also interested in understanding Alaina's reasoning around the instructional work of incorporating both forms of reasoning in a calculus course. When reflecting on reasoning from the engineering lens in the context of the Roadway Curve activity, she stated, "I wouldn't necessarily think that this [reasoning] is, like, broadly applicable to every other type of problem that we want [students] to also be able to do based off of this activity. So I would also want to make sure that [students] knew the more general way that I would probably be talking about this problem with the class." As she explained, encouraging students to use reasoning with both disciplinary lenses requires expertise on the part of the instructor, because the depth of contextual consideration present in the engineering lens is not compatible with the emphasis on generalizability from the mathematical lens. Instructors would thus need the ability to recognize which lens a student might be reasoning from and to foresee potential issues regarding an overextension of certain reasoning practices into inappropriate contexts.



Alaina went on to explain that such circumstances of overextension were very likely when working with applied problems in calculus courses.

> [The problem's author] could be a math professor who's never thought about highways before and needed to do different numbers for different problems...but then they changed the numbers too much in a way that doesn't actually make sense if you're doing these sorts of things in real life.

In this way, Alaina highlights the need for instructors to be aware of how context can typically function within calculus problem contexts to guide students in utilizing the engineering lens productively. As she stated, even when a problem in a calculus course is based in a 'real world' context, that context may not actually be realistic due to the prioritization of repeated structure and generalizability inherent in such a course.

Hypothesis for Teaching Mathematics in and for Engineering: Dually Bifocal Perspective

So, what knowledge is entailed in the instructional work of interpreting students' use of mathematics in an engineering context? Based on Alaina's case, we hypothesize that teaching mathematics in and for engineering entails knowledge stemming from what we term a "dually bifocal perspective." This perspective is dual in the sense that it involves the coordination of knowledge in and for two disciplines: mathematics and engineering. This coordination necessarily involves an awareness of both perspectives as well as the ability to "shift" back and forth between them as necessary. This perspective is bifocal in the sense of Ball (1990), and we extend her use of this term to fit our context. Bifocal lenses give the ability to focus near and far. In our context, we see Calculus instruction as premised on accurate understanding of the "nearby" student thinking and course goals, while also viewing "farther away" versions of these concepts that will be necessary for application in other contexts. Figure 2 depicts our perspective as overlaid bifocal "lenses."

Teaching mathematics in and for engineering entails bifocally viewing "nearby" student thinking and "farther away" concepts through both mathematical and engineering perspectives

Figure 2: Dually Bifocal Perspective

When an instructor can see their instruction through a *dually bifocal perspective*, this means *they are consciously aware of when their personal thinking or learners' inferences draw from mathematical concepts or from a given engineering context*. Further, with a dually bifocal perspective, an instructor can see when a learner draws on only one disciplinary lens, or when they move (perhaps tacitly) between lenses. In other words, we are saying that when instructors

can see from a dually bifocal perspective, they are better able to support their students in operating from the dual lenses of mathematics concepts and engineering context.

Finally, conscious awareness (cf. van Oers, 1998) of lenses is crucial. There are two reasons for this. First, the mathematical lens and engineering lens have competing goals, so it is necessary to "switch" between them, rather than thinking about both at the same time. Second, while an engineer may function with tacit switching between lenses, this is insufficient for *teaching mathematics in and for engineering*. Teaching entails *explicit* knowledge of "situations of justification" (Bauersfeld, 1980; Cobb et al., 1992, p. 576; Stylianides & Ball, 2008) for that topic. Here, an instructor needs conscious awareness of when they (or students) are or could be reasoning through mathematics, when they (or students) are or could be reasoning through engineering, and when such reasoning practices would or would not be appropriate.

Conclusions

Building instructor capacity requires the support of mathematics departments, particularly in creating opportunities for instructor professional development involving mathematics in and for engineering. Authentic engagement requires attention to Engineering's disciplinary perspectives and hence interaction with engineers. At the same time, instructors do not need—and are unlikely to have the time—to attain fluency in all aspects of mathematics in and for engineering. We could envision, instead, developers and instructors selecting specific topics and teaching moves, in consultation with their institution's engineering programs, that showcase a dually bifocal perspective. Getting this right would, we believe, require the dually bifocal perspective we have developed here, but the payoff for departments would be reducing the disconnect between mathematics and its use in Engineering, a long-standing challenge in post-secondary mathematics instruction.

Inquiry into the work of teaching and its entailed knowledge has the potential to advance research around cross-disciplinary mathematical learning and instruction, as well. Our framework recognizes disciplinary distinctions; we also hold them productively in tension through a turn to conscious awareness of the lenses and an explicit knowledge of situations of dual justification. As a potential conceptual and analytic framework, a dually bifocal perspective opens avenues for cross-disciplinary inquiry into how instruction and instructors can be levers of perceived disciplinary continuity in undergraduate mathematics education. A dually bifocal perspective may also lay groundwork for educative curriculum materials (Davis & Krajcik, 2005) that position instructors to mend disconnects between mathematics and engineering.

Acknowledgments

We are grateful to the members of our analysis team, and most of all, to our participant mathematics instructors and engineering graduates.

MEASURING TEACHERS' SPECIALIZED CONTENT KNOWLEDGE OF COGNITIVELY GUIDED INSTRUCTION: VALIDATION AND IMPLICATIONS OF THE CGI TKA

Debra S. Fuentes
Brigham Young University
debra.fuentes@byu.edu

Cognitively Guided Instruction (CGI) is a widely-used professional development framework that emphasizes teachers' understanding of students' mathematical thinking, yet little research has directly measured teachers' knowledge of CGI itself. This report describes the revision and validation of a CGI Teacher Knowledge Assessment (CGI TKA) designed to measure teachers' specialized CGI knowledge. Using classical test theory, factor analysis, and item response theory, the study examined the assessment's psychometric properties. A revised 30-item assessment was administered, and analyses supported a final 21-item version with strong construct validity, appropriate item functioning, and acceptable reliability. The instrument provides a sound tool for assessing CGI knowledge and informing the design and evaluation of CGI-focused professional development.

Keywords: Assessment, Mathematical Knowledge for Teaching, Professional Development, Teacher Knowledge

Introduction

Cognitively Guided Instruction (CGI) positions teachers' knowledge of children's mathematical thinking as central to effective mathematics instruction (Carpenter et al., 1999). Since its conception in the late 1980s, teachers across the United States have participated in professional development focused on CGI and it has been heralded as one of the most significant contributions to mathematics education reform in the past thirty years (Empson & Jacobs, 2008). Research has consistently shown positive associations between participation in CGI professional development and changes in teachers' beliefs, instructional practices, and student achievement (Carpenter et al., 1988; Carpenter et al., 1989; Enochs, Smith, & Huinker, 2000; Peterson et al., 1989; Philipp, 2007; Pianta, LaParo, & Hamre, 2008; Schoen Bray, Wolfe, Tazaz, & Nielsen, 2017). However, much of this research has inferred teachers' CGI knowledge indirectly through beliefs surveys, classroom observations, or student outcomes, or by measuring generalized elementary Mathematics Knowledge for Teaching (MKT) through tests like those produced by the Learning Mathematics for Teaching (LMT) project (Hill et al., 2004). These assessment approaches assume that teachers possess the *specialized content knowledge* (SCK) required to interpret student strategies and orchestrate instruction consistent with CGI principles, however a more targeted assessment could provide additional information about CGI SCK.

If CGI depends on teachers' ability to anticipate student thinking and respond instructionally (Carpenter et. al., 1988), then directly measuring teachers' knowledge of CGI is essential. A valid and reliable measure of CGI knowledge can strengthen research on CGI, inform professional development design, and support decisions about teacher learning and support. This study addresses this need by examining the validity and reliability of a CGI Teacher Knowledge Assessment (CGI TKA) by asking the following overall research questions:

1. What revisions or modifications should be made to the original CGI TKA to make it a more valid and reliable measure to teacher's specialized content knowledge of CGI?

2. How validly and reliably do the scores obtained from the revised CGI TKA measure teacher's knowledge of CGI?

Theoretical Framework

This study is grounded in theoretical perspectives on teacher knowledge, particularly the construct of *specialized content knowledge* for teaching (Ball et al., 2008; Shulman, 1986). Beyond general mathematical content knowledge, teachers require knowledge that enables them to interpret student thinking, recognize meaningful strategies, and make instructional decisions in real time (Hill et al., 2004). Within the CGI framework, this specialized knowledge includes understanding CGI problem types, common student solution strategies, and underlying principles that connect student thinking to instructional responses (Carpenter et al., 1988). The CGI TKA was designed to operationalize this form of specialized content knowledge, allowing it to be examined empirically.

The CGI TKA is grounded in methodology that suggests psychometric validity is a metric of a test, including evidence to suggest generalizability of the interpretation of the scores obtained from administration of the test (Borsboom et. al., 2004). Borsboom states that a valid test can convey the effect of variation in the attribute being measured, in this case CGI knowledge, if variation in the attribute causes variation in the test scores. This study sought to measure and explain that variation as a means of determining validity.

Methods

Participants included in-service and pre-service elementary teachers who had previously participated in CGI professional development, including story problem types and their difficulty levels, understanding student strategies for solving story problems, and implementation of math instruction using story problems in elementary classrooms. As part of this study, an original 36-item assessment was revised based on expert feedback, item analysis, and alignment with a refined table of specifications, producing a revised assessment. Data were drawn from administrations of both the original (n = 97) and revised (n = 213) versions of the CGI TKA.

Analyses proceeded in multiple phases as shown in Table 1. Classical item analysis (Novick, 1966) and distractor analysis (Gierl et al., 2017) were used to evaluate item performance and inform revisions. Exploratory factor analysis was conducted to examine the underlying structure of the revised assessment, followed by confirmatory factor analysis to evaluate model fit (Thompson, 2004). Item response theory analyses using a Rasch model were used to examine item difficulty, fit, and information (De Ayala, 2004; Wright & Linacre, 1998). Reliability of scores was estimated using Raykov's rho because of the lack of correlated errors (Bacon et al., 1995; Raykov, 1997). Comparisons between dichotomous scoring and partial credit scoring were also conducted to examine trade-offs between scoring precision and practicality (Andrich & Styles, 2002; Masters, 1982; Sideridis et al., 2016).

Table 1: Analytic Evidence Supporting Validity and Reliability of the Revised CGI TKA

Analysis	Purpose	Key Evidence
Item & Distractor Analysis	Guide item revision	Improved item functioning and distractor effectiveness
Exploratory Factor Analysis	Examine structure	Support for a single CGI knowledge factor
Confirmatory Factor Analysis	Test model fit	Strong fit indices supporting construct validity
Rasch IRT Analysis	Examine item properties	Appropriate difficulty and acceptable item fit
Reliability (Raykov's rho)	Estimate score consistency	Acceptable reliability with dichotomous scoring

Findings

The original 36-item CGI TKA format included testlet and true-false structures that limited reliable item analysis, so items were revised by repeating stems, combining related content, and converting true-false sets into multiple-choice items assessing the same concepts. These changes eliminated ten items while creating space for new items identified as missing through expert feedback, resulting in a 30-item assessment. This assessment was administered to 213 examinees.

Rasch distractor analysis illuminated item difficulties and the functionality of item distractors. It was observed that 4 of the 21 items contained one distractor that was considered *non-functioning* as it was not selected above a 10% threshold of responses. There was an additional item in which three distractors were *non-functioning*, resulting in a low-difficulty item in which 85% of the examinees answered the item correctly, but it was determined to keep the item based on other analyses. However, an interesting phenomenon occurred where one of the 21 items contained a *hyper-functioning* distractor—a distractor that was selected more frequently than the correct answer across all examinees, which contributed to the item difficulty of 31.9% which was one of the most difficult items.

Although the original organization of the test items theoretically suggested four possible constructs based on the table of specifications—(a) problem types, (b) solution strategies, (c) principles and pedagogy, and (d) evidence of base-ten understanding—results supported a unidimensional structure for the revised CGI TKA, interpreted as teachers' *specialized content knowledge* of CGI. Exploratory and confirmatory factor analyses of the same data using MPlus (Muthén & Muthén, 2012) indicated that 21 of the 30 items loaded adequately (above .32, representing approximately 10% of the variance) on a single factor and demonstrated strong model fit (CFI = 0.962 and TFI = 0.958).

Rasch item response theory analyses showed appropriate item difficulty distribution and acceptable item fit, indicating that the assessment was well-targeted to the sample. Whereas some of the distractors contained partial or incomplete understanding, the researcher theorized potential partial credit for distractors containing partial understanding. Distractors considered to contain partial accuracy were scored 0 (no understanding), 1 (partial understanding), or 2 (accurate or complete understanding). To accurately compare the dichotomous and partial credit scoring models, information criteria were calculated from the log likelihood of each of the models. The model with the lowest information criteria, indicating the best model fit, was the

dichotomously scored model. Even considering removal of each of the 10 items identified as containing distractors with useful stochastic information, none of the models fit the data better than the dichotomously scored model.

The reliability estimate for the 21-item assessment was in the acceptable range, with dichotomous scoring yielding slightly higher reliability (.837) than partial credit scoring (.826). Although partial credit scoring provided additional information for some items, the gains were modest and did not outweigh the increased scoring complexity for most intended uses. Overall, findings suggest that the revised 21-item CGI TKA with dichotomous scoring functions as a psychometrically sound measure of teachers' CGI knowledge.

Discussion

This study contributes to mathematics education research by providing evidence for a validated instrument that directly measures teachers' *specialized content knowledge* of CGI. The findings address an opportunity for more specialized, targeted assessment of CGI knowledge. By demonstrating that CGI knowledge can be assessed reliably and validly, this work strengthens the empirical foundation for future studies examining relationships among teacher knowledge, instructional practice, and student learning.

From a practice-oriented perspective, the CGI TKA has important implications for professional development. Scores from the assessment can be used to identify areas of strength and need in teachers' CGI knowledge, inform the design of targeted professional learning experiences, and evaluate the effectiveness of CGI-focused professional development or pre-service preparation programs over time. The assessment also offers potential for broader applications, such as supporting instructional coaching or informing decisions about advanced CGI training.

Methodologically, the use of (a) classical test theory for item and distractor analyses, (b) exploratory and confirmatory analyses, (c) item response theory analyses, (d) comparison between dichotomous and partial credit scoring, and (e) reliability analyses collectively suggest a thorough validation of the CGI TKA.

Implications and Conclusions

The CGI TKA is a methodologically robust, psychometrically sound tool for measuring teachers' *specialized content knowledge* of CGI. Its use can support both research and practice by making teachers' CGI knowledge visible and measurable. Current use of the CGI TKA supports consideration of the effectiveness of professional development and need for further support of teachers and school leaders. It is often used to assess understanding and changes in CGI knowledge among preservice teachers during teacher preparation programs and with practicing teachers during inservice professional development. However, this assessment could potentially be used for teacher certification, advancement, or endorsement purposes if so desired. Additional validation may be necessary to support use of the CGI TKA as a criterion-referenced test (Kane, 2013).

Future research should examine how CGI TKA scores relate to instructional practice and student outcomes and explore the use of the instrument with larger and more diverse teacher populations, accounting for various demographics to suggest validity for multiple groups of examinees and, therefore, reducing the potential for bias. Together, these efforts can deepen understanding of how teacher knowledge functions within CGI and how professional development can be designed to support meaningful instructional change. Additionally, an alternate form of the CGI TKA could be created and validated to provide more robust

psychometric opportunities for pre- and post-testing scenarios to demonstrate knowledge growth and program effectiveness.

Elementary Mathematics Specialists (EMSs) require robust Mathematical Knowledge for Teaching (MKT) to effectively support student learning and teacher development. This convergent mixed methods study examined longitudinal shifts in MKT of 26 novice EMSs across the first 3 years of a 5-year EMS preparation program. Participants completed mathematics and coaching endorsement courses, coupled with ongoing professional learning communities and mentoring. MKT was measured at three time points, and interviews were conducted at the end of Year 3. Results indicated significant gains in MKT during courses, with knowledge largely sustained through Year 3. Qualitative findings associate growth with increased attention to vertical content alignment, deeper analysis of student thinking, and greater curricular flexibility. Findings show the important role of particular learning experiences in developing EMSs' MKT.

Keywords: Elementary School Education, Mathematical Knowledge for Teaching, Professional Development, Teacher Knowledge

Introduction

Elementary Mathematics Specialists (EMSs) are mathematics teachers and leaders who fill a variety of roles in elementary schools, including: (a) generalist classroom teacher, (b) specialist mathematics or STEM teacher, (c) Multilingual Learner, Special Education, Early Intervention Program, or gifted interventionist, and (d) teacher leader or coach (Association of Mathematics Teacher Educators, AMTE, 2024). To effectively serve in these roles and effect change in their settings, EMSs need well-developed mathematical content knowledge they can draw from in their work with students, teachers, and school leaders. The mathematical knowledge for teaching (MKT) framework (Ball & Forzani, 2010; Ball et al., 2008; Hill, 2010) includes *specialized content knowledge* focused on teachers' abilities to: (a) analyze and interpret students' mathematical thinking and ideas, (b) use multiple representations of mathematical concepts, and (c) define terms in mathematically correct and accessible ways. Notably, research focused on the extent to which EMS preparation programs increase MKT illuminates positive but mixed findings (Campbell & Malkus, 2014; Kutaka et al., 2018; Rigelman & Lewis, 2023).

Although prior studies have documented some increases in MKT following EMS courses or professional development, less is known about the longitudinal stability and developmental trajectory of MKT as a measured construct (Campbell & Malkus, 2014; Kutaka, et. al., 2018). This study addresses the conceptual tension between MKT as an assessable construct and MKT as situated professional knowledge, examining whether measured changes persist over time and if and how those changes align with teachers' own accounts of their learning (Hill & Chin,

2018). We examined 26 novice EMSs whose MKT was assessed longitudinally over three years during a rigorous EMS preparation program and their reflections about their learning.

Research Questions

1. To what extent did novice EMSs' MKT change across an EMS preparation program?
2. How did the novice EMSs describe changes in content knowledge, and how did that align with the shifts measured by the LMT?

EMS Preparation Program Description and Participants

Participants

The 26 EMSs' primary responsibility was teaching students, and while novice EMS teacher leaders, the participants were experienced teachers, averaging 12+ years of experience. All held master's degrees in education. They largely identified as persons of color (70%) and worked in 23 urban-situated elementary schools with underserved student populations.

Program Description

The EMS preparation program included seven university courses leading to professional endorsements in Elementary Mathematics (K-5ME) and Coaching (TCSE), with concurrent participation in professional learning communities (PLCs) and individual mentoring that extended beyond their coursework (see Table 1). Grounded in research and professional recommendations (AMTE, 2024, 2017), overall goals of the Elementary Mathematics endorsement courses were to develop: (a) ambitious and equitable mathematics instructional practices (Aguirre et al., 2024; Carpenter et al., 2015; National Council of Teachers of Mathematics [NCTM], 2014, 2020); (b) deep and broad knowledge of elementary mathematics, including *specialized content knowledge* (i.e., "mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students" [Ball et al., 2008, p. 399]); (c) productive mathematics beliefs; and (d) knowledge and utilization of mathematics education standards, research-informed curricula and resources, and networking opportunities. When considering MKT development, we conceptualized it as socially mediated and participation-based, drawing on communities of practice theory (Wenger, 1998). This positions teacher knowledge as evolving through engagement in shared mathematical work across courses and learning communities.

Table 1: Timeline and Project Elements Aimed at Preparing and Supporting EMSs

Year 1			Year 2		Years 3–5
Fall	Spring	Summer	Fall	Spring	
TCSE Course: Teacher Support & Coaching	K-5ME Course: Number & Operations	K-5ME Course: Data & Probability	K-5ME Course: Algebra & Rational Number *and* Coaching Internship	K-5ME Course: Geometry & Measurement *and* Math Internship	
PLCs and Mentoring	PLCs and Mentoring		PLCs and Mentoring	PLCs and Mentoring	PLCs and Mentoring

Methodology

This study used a convergent mixed methods design (Creswell, 2014), with the initial analysis considered separately and then merged to compare, contrast, or validate findings. The EMSs' MKT was measured prior to the program, upon conclusion of the related mathematics course, and at the end of Year 3. The intent was to consider if the participants' MKT significantly increased during courses and if that was maintained over time. MKT data were collected using the Learning Mathematics for Teaching (LMT), which focuses on *specialized content knowledge*, common content knowledge, and knowledge of content and students (Ball et al., 2008; Hill et al., 2004). The LMT includes three subscales—number and operations, algebra, and geometry—and person abilities are reported as IRT scores. Data were also gathered via eight individual (II) and three focus group (FG) interviews, with questions focusing on: (a) possible changes in knowledge of elementary mathematics content, and (b) how program learning experiences influenced knowledge development. Hierarchical linear modeling of the IRT person ability scores for each test occasion nested in EMSs describes shifts in content knowledge for the entire group of participants. The interview data were analyzed using the constant comparative method. Changes in LMT subscale scores for individuals were connected to the findings of the interview data for the same individuals.

Findings

Analyses of the LMT data show significant positive changes in MKT after three years of the program, with most improvement occurring in the first two years as evidenced by significant linear and quadratic hierarchical mixed models with test occasions nested in individuals (see Table 2).

Table 2: Type III Tests of Fixed Effects – Quadratic Mixed Models by Content Domain

Outcome	Effect	Num df	Den df	F (p)
Geometry	Intercept	1	35.20	1.75 (.194)
Geometry	Linear Time	1	30.23	28.97 (<.001)
Geometry	Quadratic Time	1	30.05	19.38 (<.001)
Algebra	Intercept	1	32.15	0.02 (.878)
Algebra	Linear Time	1	32.24	17.27 (<.001)
Algebra	Quadratic Time	1	29.34	8.97 (.006)
N&O	Intercept	1	39.07	5.67 (.022)
N&O	Linear Time	1	32.49	7.43 (.010)
N&O	Quadratic Time	1	32.70	6.12 (.019)

Note. Satterthwaite degrees-of-freedom approximations used throughout.

Interview data provided insights into how participants described their shifts in content knowledge as situated in practice and connected to particular learning experiences. Analyses show that participants especially attributed growth in MKT to: (a) new knowledge of vertical alignment of mathematics content across K-5 grade levels (*horizon knowledge)*, (b) more robust understanding and expectations of students' mathematical thinking and reasoning abilities (*specialized content knowledge related to student thinking)*, and (c) increased understanding of curricular materials as resources with potential need for modification *(curricular knowledge)*. From a communities of practice perspective (Wenger, 1998), these shifts reflect not only changes in knowledge but also changes in participation, expanded engagement across grade-level

boundaries, deeper involvement in collective sense-making about student thinking, and movement from curriculum implementers toward curriculum interpreters and contributors.

Relationships between the measured changes in MKT and the participants' perceptions of those shifts obtained through interview data were also explored to consider alignment among the two data sources. These are shown with positive (+) or negative (-) changes in 0.2 IRT score intervals. In most cases, the shifts described are consistent with the changes measured via the LMT, and many of the participants described their knowledge growth as situated in practice and linked to specific experiences in the EMS preparation program.

For example, when considering *horizon knowledge*, one participant stated:

> I think working with all of us as a whole group because we each play different roles at different levels in elementary education. And so being able to look at the content more K-5 really helped me understand how it builds on each other and how I can better serve the groups that I'm with. (II, ll. 50–54)

Alg: ++
Geo: ++++++++
N&O: --

A statement that reflected *specialized content knowledge related to student thinking* includes:

> … some of the different ways that students think allow me to really think further and differently about how students explain their responses … I'm able to give students the freedom to think about it and share the way they learn it, which then increases my understanding and what I'm able to truly allow them to do to demonstrate their knowledge. (II, ll. 95–106)

Alg: +++++++++
Geo: ++++++
N&O: ++++

When considering *curricular knowledge*, one participant commented:

> I think before the program, I was kind of wary to veer off from like the county plan or what I was told to do. … [The program] has just given me like the tools and the ability to deliver mathematics the way that I want to and also stand up for that decision. (II, ll. 19–25)

Alg: +++
Geo: ++++
N&O: ++++++

Conclusion

Overall, findings confirm and extend the extant literature, illuminating the complexity of changes in EMSs' MKT and associated connections with their own teaching and program learning experiences. With previous research on EMS programs showing mixed findings when it comes to MKT (e.g., Campbell & Malkus, 2014; Kutaka et al., 2018), it is optimistic that the learning experiences provided in this program supported significant growth in and retention of this knowledge.

General consistency between the participants' descriptions of the shifts in MKT with the measured changes using the LMT illuminate internalized growth in MKT. Interview data suggest preparation program components such as rigorous coursework, collaboration with colleagues across grade levels, and ongoing interaction beyond coursework supported gains and retention of MKT throughout the project, suggesting shifts in MKT may be socially mediated and situated in communities of practice as Wenger (1998) described. Continued study of these EMSs and how they draw from their content knowledge when implementing and advocating for ambitious and equitable mathematics instruction offers an important opportunity to advance the knowledge base on EMS preparation.

MATHEMATICAL KNOWLEDGE FOR TEACHING AND DISCOURSE FACILITATION IN INTERMEDIATE CLASSROOMS

David Hung
Faculty of Education, University of Ottawa
david.hung@uottawa.ca

Teachers vary considerably in their ability to facilitate productive mathematical discourse yet research inadequately explains this variation. This multiple case study investigated how mathematical knowledge for teaching and pedagogical expertise influenced discourse facilitation among four expert intermediate mathematics teachers. Drawing on Ball, Thames, and Phelps' (2008) framework, the study examined teachers' specialized content knowledge, knowledge of content and students, and curriculum knowledge through interviews, classroom observations, and fields notes. Findings revealed that teachers with deeper mathematical understanding navigated student contributions more flexibly, recognizing mathematical validity in unexpected solution paths. Teachers demonstrated curriculum knowledge understanding essential for discourse facilitation. All teachers acknowledged that highly procedural topics resist discourse approaches, suggesting that mathematical knowledge for teaching includes knowing precisely when discourse serves specific learning goals.

Objectives and Research Questions

Teacher quality represents the most significant school-based factor influencing student achievement (Rivkin et al., 2005; Wayne & Youngs, 2003). However, identifying specific teacher attributes and practices that improve student learning remains challenging. Research consistently demonstrates wide variation in teacher effectiveness, yet explicating what effective teachers know and do proves elusive (Hill et al., 2005; Stigler & Hiebert, 2009). Mathematical knowledge for teaching (MKT) has emerged as a critical construct explaining teacher effectiveness (Ball et al., 2008; Hill et al., 2005). MKT encompasses specialized mathematical knowledge beyond what typical adults possess, including: recognizing and analyzing diverse solution strategies, identifying the mathematical point in student contributions, sequencing examples appropriately, and choosing representations that illuminate mathematical structure (Ball & Bass, 2003). Research demonstrates that teachers with stronger MKT produce greater student achievement gains (Hill et al., 2005; Baumert et al., 2010).

Mathematical discourse places particular demands on teacher knowledge. When students explain reasoning, offer unconventional strategies, or propose incorrect solutions, teachers must make rapid, complex decisions: Is this mathematically valid? How does this connect to learning goals? Which student ideas should I pursue? (Stein et al., 2008; Stockero & Van Zoest, 2013). These in-the-moment decisions require robust mathematical understanding integrated with pedagogical expertise (Jacobs et al., 2010; Sherin et al., 2011). Research further suggests that productive discourse depends on teachers' capacity to elicit, interpret, and build upon student reasoning in ways that advance mathematical learning (Chapin et al., 2013; Selling, 2016).

This study investigates: How does teachers' mathematical knowledge for teaching and pedagogical expertise influence their facilitation of discourse in Grade 7 and 8 mathematics classrooms? Sub-questions explored: (1) how mathematical content knowledge shapes teachers'

responses to student contributions during discourse; (2) what role curriculum knowledge plays in discourse planning and facilitation; and (3) how teaching experience influences discourse success.

Theoretical Framework

This study draws on Ball, Thames, and Phelps' (2008) framework distinguishing six domains of mathematical knowledge for teaching: common content knowledge (mathematical knowledge any educated adult should possess), specialized content knowledge (mathematical knowledge unique to teaching), knowledge of content and students (knowledge about how students think about, know, or learn particular mathematical content), knowledge of content and teaching (knowledge about teaching particular mathematical content), horizon content knowledge (knowledge of how mathematical topics relate across curriculum), and knowledge of content and curriculum (knowledge about curricular materials and programs).

The study focuses particularly on specialized content knowledge and knowledge of content and students, as these domains prove especially relevant for discourse facilitation. Specialized content knowledge enables teachers to recognize mathematical validity in unconventional student strategies, decompose mathematical ideas for instruction, and select representations illuminating mathematical structure (Ball et al., 2008; Ma, 1999). Knowledge of content and students enables teachers to anticipate common misconceptions, interpret student thinking during discourse, and craft questions accessing student reasoning (Hill et al., 2008; Carpenter et al., 2014).

Additionally, the study employs Shulman's (1986, 1987) construct of pedagogical content knowledge, which emphasizes transformation of content knowledge into forms teachable and learnable by students. Extending this framework to mathematical discourse, researchers have identified key aspects of pedagogical content knowledge for discussion-based teaching, including knowing which mathematical topics lend themselves to student discussion, how to frame problems inviting multiple solution strategies, and how to sequence student contributions to build collective understanding (Lampert, 1990; Smith & Stein, 2011).

Methods

Participants and Context

Four intermediate mathematics teachers participated in this multiple case study, purposefully selected for their commitment to and expertise to discourse-based instruction. All participants taught Grade 7 and/or 8 mathematics in schools within a large urban district. Three participants held additional qualifications in mathematics, representing specialized professional learning beyond initial teacher certification. While participants varied in cumulative years of teaching experience, they all integrated classroom discourse into their instructional practices frequently.

Data Collection

Data collection followed case study protocols (Merriam, 2009; Stake, 1995) and included: (1) two semi-structured interviews per teacher, one conducted before and one after classroom observations; (2) two 45-minute classroom observation sessions per teacher, audio-recorded to capture discourse patterns; (3) researcher field notes documenting classroom environment, student interactions, and teacher moves; and (4) demographic data from school websites and publicly available statistics. Interview protocols explored teachers' beliefs about discourse, implementation strategies, challenges encountered, and decision-making processes. Observations captured naturally occurring discourse during mathematics instruction.

Data Analysis

Analysis followed Merriam's (2009) two-stage process for multiple case studies. Firstly, each case was analyzed individually using Kvale's (2007) five-step meaning condensation process to identify themes within teacher practice. Interview transcripts were analyzed by extracting natural meaning units and grouping them into emergent categories using NVivo software. Secondly, cross-case analysis was conducted to identify commonalities and variations across the four teachers (Merriam, 2009; Stake, 1995). Trustworthiness was established through triangulation of multiple data sources (interviews, observations, field notes) and by providing interview transcripts to participants for review and approval.

Results

Analysis revealed four major themes characterizing the relationship between teacher knowledge and discourse facilitation.

Theme 1: Specialized Content Knowledge Enables Flexible Responding

Teachers with stronger mathematical knowledge demonstrated greater flexibility responding to diverse student contributions. When students offered unconventional solution strategies, these teachers quickly assessed mathematical validity, identified the mathematical principle underlying student thinking, and formulated questions helping students refine or extend ideas. Teachers holding mathematics specialist qualifications exemplified this flexibility. During observed lessons, when students suggested approaches that differed from standard algorithms, these teachers recognized the mathematical validity and asked probing questions. For example, during an observed lesson, one participant, who held a doctoral degree in Biology, selected four student answers to use for lesson consolidation. She systematically asked students to explain their strategies, built upon their reasoning, and sequentially transitioned from one strategy to the next. She reached the final student work sample and summarized everything coherently before the end of the lesson. After the lesson, she shared that she picked the four student works and presented them to enable students to understand the range of strategies that can be used when solving math problems and that some strategies are shorter and simpler than others. Specialized content knowledge allowed her to do such consolidation at the end (Shulman, 1986).

Theme 2: Curriculum Knowledge Frames Discourse Decisions

All teachers demonstrated strong knowledge of Grade 7-8 curriculum expectations and learning progressions. They all held specialized math qualifications. This curriculum knowledge directly shaped how they planned their lesson around the use of discourse: specifically, which mathematical ideas to emphasize, what prerequisite understanding to activate, and how concepts are connected across grades. One teacher explained the importance of understanding prerequisite knowledge, recalling: "I remember when I came to Grade 7 as a new teacher, I did not know what the Grade 7s should know by [the end of] Grade 6. So, knowing all that is important." Curriculum knowledge also informed in-the-moment decisions about which student contributions to pursue and what questions to ask. Towards the end of the lesson, teachers selected student works to showcase and those that advanced learning toward learning goals (Shulman, 1986; Smith & Stein, 2011).

Theme 3: Experience Enables Anticipation and Preparation

Teaching experience correlated with discourse success. Teachers with more years teaching intermediate mathematics demonstrated superior ability to anticipate student difficulties and to prepare questions addressing common misconceptions. The participants, who are all experienced teachers, described how planning discourse-rich lessons became more efficient over time. One participant noted that "preparing such lessons [discourse-based] now took much less time

because of a well-developed repertoire of questions, anticipated student responses, and strategies to address them." Another participant described the process of trying to "anticipate what the different strategies might be, in advance" and prepare corresponding questions for each approach. Furthermore, all the participants managed classroom logistics more efficiently, as due to their experience and habit, they found it easier to form groups quickly and were more likely to facilitate a productive lesson using discourse. One teacher added that "if my students are not in the mood to talk or if they are tired, I am going to forego talk for another teaching strategy" (Interview). They all agree that teachers need experience as well as strong mathematical knowledge, suggesting that mathematical knowledge and experience work synergistically (Hiebert & Grouws, 2007).

Theme 4: Recognizing Discourse Limitations Demonstrates Expertise

Significantly, all teachers acknowledged that certain mathematical content resisted discourse approaches. Highly procedural topics requiring foundational knowledge, they argued, benefited from explicit teacher demonstration before student exploration. One teacher reflected on teaching the Pythagorean theorem: it would be "hard to teach students how to find the length of the diagonal in a right-angled triangle by asking students to talk as they have no knowledge about the existence of the Pythagorean Formula and how to use it" (Interview). This recognition that discourse does not universally serve all learning goals reflects pedagogical sophistication (Hiebert & Grouws, 2007; Lampert, 2001). Rather than ideologically committing to discourse regardless of content, teachers exercised judgment about when discourse advanced learning versus when other approaches proved more effective.

Discussion and Implications

This study illuminates the complex knowledge base underlying effective mathematical discourse facilitation. Findings confirm that mathematical knowledge for teaching matters significantly (Ball et al., 2008; Hill et al., 2005), while extending understanding of specifically how MKT enables discourse success. Specialized content knowledge enabled flexible response to diverse student contributions. These differences were visible when teachers asked probing questions to advance student thinking and when they connected student ideas to mathematical big ideas. This finding suggests that professional development targeting discourse facilitation must strengthen teachers' mathematical understanding, not just teach pedagogical moves (Ma, 1999; Stigler & Hiebert, 2009). The deeper teachers' content understanding, the more effectively they can guide students toward multiple solution pathways and deeper mathematical understanding.

Curriculum knowledge, one of Shulman's (1986) three categories of content knowledge, plays an important role in effective mathematics teaching. Teachers needed understanding of learning progressions, prerequisite concepts, and how topics connected across grades to make productive discourse decisions. This suggests professional development should explicitly address how to orchestrate productive mathematical discussions, including anticipating student strategies and sequencing contributions to build mathematical understanding (Smith & Stein, 2011). Professional development should make this full process explicit to teachers so that they understand how discourse fits and connects across concepts and grade expectations.

The finding that experience enables anticipation of students' questions and responses aligns with research on teacher expertise, which shows that teachers can prepare for classroom interactions by anticipating what students will think and do (Stein et al., 2008). However, experience must be combined with strong mathematical knowledge for developing expertise (Ball et al., 2008). Professional development facilitators are encouraged to provide teachers with

collaborative design opportunities where they map out discourse-based lessons, explicitly script questions, and anticipate student questions and prepare the responses.

The acknowledgment that discourse does not universally serve all mathematical learning goals demonstrates adaptive expertise. Rather than viewing discourse as a pedagogical panacea, teachers exercised judgment about when discourse advanced learning. This finding cautions against treating any single approach as always appropriate, but instead emphasizing the need to match instructional methods to learning goals (Hiebert & Grouws, 2007).

For teacher education, findings suggest three priorities: (1) strengthen prospective teachers' mathematical knowledge through content courses emphasizing specialized knowledge needed for teaching; (2) provide extensive practice analyzing and responding to student mathematical thinking through video case studies and clinical experiences (Sherin et al., 2011); and (3) develop adaptive expertise through opportunities practicing pedagogical decision-making in varied contexts.

Future research could investigate how teachers' MKT develops over time through discourse practice, examine the specific mathematical knowledge needed for different content domains, and explore how professional learning experiences strengthen teachers' capacity for discourse facilitation.

Keywords: Mathematical Knowledge for Teaching, Rational Numbers, Teacher Knowledge

Researchers have explored how students' conceptual knowledge does not develop if students only have the opportunity to procedurally memorize algorithms, such as invert-and-multiply (e.g., Behr et al., 1992; Cramer et al., 2010; Young & Zientek, 2011). Investigations of teacher knowledge have identified challenges including struggles to utilize appropriate representations and limitations in teachers' understandings of fraction division and multiplication (e.g. Armstrong & Bezuk, 1995; Borko et al., 1992; Izsák, 2008; Post et al.,1988). This study focused on (a) whether teachers were able to appropriately answer two questions about a particular recipe and (b) what mathematical approach they used to solve each question.

Thirty practicing teachers in grades 3–9 from four states responded to both items as part of a larger project. Item 1 asked how many loaves could be made given a certain amount of sugar, while Item 2 asked how much sugar would be needed for a certain number of loaves. Interviews were conducted via Zoom with participants using a Google Jamboard to show their thinking. Interviews were transcribed verbatim. Two researchers coded each of the 60 teacher responses for correctness (remainder correct, without remainder, incorrect) with 87% agreement. Next, researchers coded the mathematical approach: multiply, reciprocal, cross multiply, numeric, visual, and repeated addition. One response did not include a solution. Video and/or Jamboards were consulted to look for disconfirming and confirming evidence.

Overall, the majority of responses (42 out of 59) were coded as Correct. Many teachers successfully used a standard algorithm, including multiplication (particularly for Item 2), reciprocal (changing a division problem to multiplying by the reciprocal), and cross multiply (Table 1). Across the majority teachers who were able to correctly solve two items, we observed an important reasoning that underlined the correctness. The correctness appeared to hinge on identifying the situation as either multiplication or division rather than on the approach. However, identifying the situation correctly did not guarantee a correct solution.

Table 1: Standard Algorithm Approaches Across Items & Correctness

Code	Total	Item 1			Item 2		
		Correct	Incorrect	No Answer	Correct	Incorrect	No Answer
Multiply	24	1	3	1	17	2	0
Reciprocal	11	6	1	2	0	2	0
Cross multiply	9	5	0	0	3	1	0

DO GSI'S LOOK FOR SOLUTIONS SIMILAR TO THEIR OWN WHEN ASSESSING STUDENTS' ATTEMPTS AT COVARIATIONAL REASONING?

Irma E. Stevens
University of Rhode Island
irma.stevens@uri.edu

Keywords: Undergraduate Education, Teacher Noticing, Precalculus, Cognition

Given the impact covariational reasoning—reasoning about how two quantities change together (Carlson et al., 2002)—has in supporting productive meanings in precalculus concepts, researchers have provided (undergraduate) students with repeated opportunities to engage in covariational reasoning (e.g., Moore & Carlson, 2012; Yu, 2022). Some research in professional development settings (e.g., Clark et al., 2008) and with secondary educators (e.g., Teuscher et al., 2016; Liang, 2025; Tallman & Frank, 2020) have analyzed the ways in which instructors can decenter from their own mathematical meanings to understand and support their students' mathematical meanings, including covariational reasoning. However, an understudied population is the Graduate Student Instructors (GSIs, hereafter), instructors who are often responsible for teaching hundreds of undergraduate students over their graduate program, but who often receive little pedagogical training. Thus, via a study with 11 GSIs enrolled in a teaching undergraduate mathematics seminar, I aimed to answer the following research question: Do GSIs look for solutions similar to their own when assessing students' covariational reasoning?

To answer this research question, I asked the 11 GSIs to complete an assignment that was adapted from the *Bottle Problem* (Carlson et al., 2002) (*Adapted Bottle Problem*, hereafter) and submit a video describing their solutions. They then submitted a second video describing how they would support two Applied Precalculus students who completed the same *Adapted Bottle Problem* assignment. I used two frameworks used to analyze the data (covariational reasoning (Carlson et al., 2002) and SNR (Herbst et al., 2023). The SNR framework is used to describe a student contribution's serviceability (the extent a contribution supports the lesson goal), normativity (the extent a contribution aligns with the norms of the instructional situation), and responsiveness (the extent a contribution answers the problem posed).

Prior analysis of GSI's noticing of student descriptions using the SNR framework (Herbst et al., 2023) indicated that GSIs tended to notice serviceable and non-normative aspects of students' work (Stevens, 2026). The preliminary analysis reported here compares initial results with the GSI's own descriptions of solutions to the problems. The poster will include two preliminary results. First, I provide an example of a GSI who comments on positive aspects of student work dissimilar from their own. Second, I provide an example of a GSI who comments on negative aspects of student work similar to their own. The first result indicates GSIs' capacity to decenter from their own reasoning to identify positive aspects of students' work despite reasoning and a result that was different than their own. This result shows promise that GSIs who are new to undergraduate instruction can move beyond the correctness of a students' solution (Jacobs et al., 2010) and highlight the advantages of covariational reasoning. This contributes to literature on GSI's mathematical knowledge for teaching (Ball et al., 2008). However, it does not indicate if and how this knowledge is used in practice. The second result indicates potential disparities between GSI's own work and the expectations they have for their students. Continued analysis is needed to better understand the extent to which GSI's responses to student contributions align and misalign with their own reasoning.

HOW SEMANTIC STRUCTURE AND PROBLEM CHARACTERISTICS SHAPE REPRESENTATION CHOICE IN FOURTH GRADE STUDENTS' SUBTRACTION PROBLEM-SOLVING

Mary Oluwatoyin Ajani
Pennsylvania State University
moa5622@psu.edu

Research has established that subtraction is not a single operation but a set of semantic structures. However, little is known about how students' representational choices mediate their problem-solving processes across different tasks. This task-based research investigates how semantic structures and problem characteristics of subtraction context create opportunities for different representational practices, and how those representations shape students' problem-solving processes. Data was drawn from videotaped and audio-recorded interview, transcribed, and coded. Findings revealed that representational choices mediate interpretation, reasoning and strategy choice with semantic structure and problem characteristics shaping the way students interpret the task situation. The study emphasized the need to reconceptualize subtraction instruction as a problem-solving practice that privileges structural sense-making and flexible use of representations.

Keywords: Problem Solving, Elementary School Education, Mathematical Representation

Word problem tasks place distinct cognitive demands that extend beyond those required for arithmetic or algebraic tasks presented in purely symbolic form. It requires the coordination of multiple advanced cognitive skills, including language comprehension and logical reasoning, which are less central when mathematical expressions are already provided (Wong & Yip 2023). To successfully solve a word problem, student must identify the problem type, make sense of the context, and recognize its underlying semantic structure, often referred to as schema identification. They must also determine which quantity is unknown within that structure; only after completing these interpretive steps can students formulate a suitable mathematical equation and proceed to solve the problem (Carpenter & Moser, 1982/2020; Wong & Yip, 2023).

Previous studies by Jerman (1973), Cook (1973) and Searle et al. (1974) focused on classifying word problems by surface-level features such as syntax, vocabulary, and word count, highlighting how linguistic form can affect problem difficulty. This align with a synthesis of research by Andersson (2007), Mayer (2001), Nathan and Kintsch (1992), Daroczy et al. (2015), and Carpenter and Moser (1982/2020) indicating that variation in mathematical solution strategies is a function of three interrelated dimensions: linguistic factors (e.g., wording, semantic categories, propositional structure), cognitive features (e.g., schema activation, metacognition, retrieval fluency), and numerical factors (e.g., number magnitude, position of the unknown). Likewise, Lean et al. (1990) and Daroczy et al. (2015) noted that problems containing explicit semantic cues—such as conjunctions (e.g., and), adverbs (e.g., left, more than, less than), or determiners (e.g., each)—often guide students toward a particular operation.

Meanwhile, representations are key elements in building conceptual understanding, enabling students to visualize, manipulate, and connect mathematical ideas across different forms of expression. The effective use of these representations relies on a critical cognitive process and translation between systems. These include signs, symbols, diagrams, objects, images, and graphs which are fundamental tools in mathematics teaching and learning (Mainali, 2021). Research on children's subtraction problem solving shows that learners employ a variety of

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

representations such as concrete manipulatives, visual models, symbolic/numeral, algorithms (vertical/horizontal) notation depending on the task context and their own strategy preferences (Barmby, 2009; Björklund et al., 2019; Boulton-Lewis et al., 1996; Bruner, 1966 cited in Presno, 1997; Center, 2019; Li et al., 2018).

Existing studies on word problem-solving often focus on outcomes, strategy selection or categorized problems by semantic structure rather than in the moment interpretive work students engage in before computation begins. Building on this body of work, this study addresses the non-obvious cognitive processes children engage in when solving subtraction word problems, linking how student's representational choices interact with semantic structure to shape reasoning, strategy development, and sense-making during subtraction word problem solving. Thus, the purpose of this study is to investigate these processes through the following questions:

1. How do semantic structures and problem characteristics of subtraction word problems create opportunities for distinct problem-solving approaches?
2. How do students' representational practices mediate their problem-solving processes across different semantic structures of subtraction problems?

Theoretical Framework

The Boulton-Lewis model (1993) provides the theoretical framework for this study. It classifies mathematical representations into three distinct categories based on the structure and associated cognitive load they placed on the learner. Material strategies or analogs involve using concrete objects or physical visualizations to represent mathematical concepts. Discipline-specific representations are formal and conventional tools adopted by the mathematics discipline, such as written algorithms, symbols, and number lines. Mental/Verbal strategies by contrast refer to internal models, and self-generated processes that children employ in preference to or alongside formal procedures to support mathematical reasoning. Within this framework of representation use, different categories of representations serve distinct pedagogical functions in learning subtraction. However, existing research has often examined representation use separately from the semantic structure of word problems. Specifically, subtraction research typically isolates strategies and representations, whereas word-problem research emphasizes schema identification, linguistic cues, and semantic structures (Boulton-Lewis, 1993; Carpenter et al., 1981; Carpenter & Moser, 1982/2020; Daroczy et al., 2015; Wong & Yip, 2023).

In this study, the framework is used as an analytical lens through which the participants' problem-solving process was examined, revealing how representational choice mediates the relationship between semantic structure and problem characteristics. Thus, create affordances or constraints in the transition from concrete modeling to abstract reasoning in subtraction.

Methods

Design and Participant

This study adopts a qualitative single case study design using a task-based interview approach to examine student's solution processes, strategy use and representation choices to subtraction problems. A single-case design is appropriate for such an exploratory analysis as it allows for a rich, contextualized examination of cognitive phenomena within a specific, bounded instance while the task-based interview protocol served as the primary research instrument (Goldin, 2000). During the interview, follow-up questions were posed to the student on all items to elicit the students' thinking and justification. The study used an eight-year-old male student (pseudonym: Ini) currently enrolled in the fourth grade at a public elementary school.

Data Sources

Two subtraction tasks were selected based on Carpenter and Moser (1982/2020) taxonomy: Task 1, represents a comparison/joining problem (involves determining the difference between two quantities) while Task 2 represents a multi-step subtraction problem (combines both a Change/Start Unknown structure and a Comparison structure). It requires that students coordinate sequential operations in which the result of the first calculation becomes the input for the second.

> Task 1: Morgan wants to buy the next book in her favorite series when it is released next month. So far, she has saved $15. The book will cost $22. How much more money does Morgan need to save so that she can buy the book? (NCTM, 2014).
>
> Task 2: Mariam will be 20 years old in 3 years. Her brother, Dahlan's age is 2 years more than Mariam. What is Dahlan's age now? (Ling & Ghazali, 2014).

Data Analysis

The interview session was both video and audio-recorded and was subsequently transcribed, reviewed, and coded. Supplementary data sources included the student's written work and researcher field notes. The analysis employed a hybrid coding approach, with criteria synthesized from the frameworks of Carpenter and Moser (1982/2020), Torbeyns et al. (2009), Rosenthal and Resnick (1974), and Boulton-Lewis (1993). Strategies were coded according to the type of operation and reasoning used, such as direct subtraction, counting up, decomposition, matching/modeling, and trial-and-error. First, I considered the semantic structure and the position of the unknown in the corresponding mathematical equation in the tasks. Secondly, representations were coded deductively using Boulton-Lewis's model of mathematical representations: categories of Material Strategies (e.g., fingers, pizza drawings), Discipline-Specific Representations (e.g., equations, number lines, standard algorithms), and Mental/Verbal Strategies (e.g., mental regrouping, verbal explanations). For example, when the student hypothetically used a number line to explain a comparison problem to a peer, this very episode was coded for representational form and later analyzed for its function in supporting explanation. The episode was then interpreted in relation to the problem's semantic structure, illustrating how representation mediated the student's problem-solving process. The task-based interview took one and a half hours, guided by the two research questions. To reduce researchers' bias, video recordings, verbal explanations, field notes, and student work artifacts were triangulated to support interpretations of the student's reasoning.

Results

Influence of Semantic Structure and Problem Characteristics on Problem-Solving Strategies

Ini initially used the standard algorithm (conventional step-by-step mathematical problem-solving process) to solve Task 1. To probe further into why he used this strategy, I asked him to explain his understanding of the task by asking what it was saying. He interpreted (summarized) the task as "*What's the answer to 22 minus 15?"*

From his responses, he identified key operations of the problem based on the linguistic clue "*how many more*," which he interpreted as signaling subtraction (minus), thus guiding his choice of strategy direction. I then asked:

> Interviewer: What about the problem helped you to decide how to solve it the way you did?

Ini: First, because you said that we're going to do subtraction numbers, and because subtraction numbers always have the bigger number on top and then when I read and fought around the question, I saw how many more, how many much more. And then I was like, oh, so this is subtraction… *That's the (unknown) number that we have to find.*

He explicitly identified the unknown number (7) as "the answer" and "the unknown number that we have to find" framing the problem as a missing addend (15 + ? = 22) while he calculated the difference using direct subtraction. This aligns with research indicating that the semantic structure of word problems often influences the strategies children select.

Ini's ability to connect the larger quantity to the minuend and the smaller quantity to the subtrahend demonstrates an understanding of subtraction as a structured relationship between quantities. This reasoning was shaped by the problem characteristics, which guided how the student identified and organized quantities prior to computation. Previous research similarly highlights that attention to problem characteristics enables students to meaningfully map contextual information onto symbolic expressions, thereby supporting conceptual understanding of subtraction (Carpenter et al., 1999; Fuson, 2003).

The second task was presented, and Ini immediately recognized it as a two-step subtraction word problem.

Ini: This is a two-step word problem.
Interviewer: Two-step word problem? How do you know?
Ini: I have to figure out what twenty minus three is. Which is? Twenty-eight, no, twenty seven and then add two more which means that, um, this is for the M is for Maria and the B is for brother, which means, um, twenty-seven plus two equals twenty-nine. How I first knew it was going to be a minus problem is that like Maria would be, that would be 20 years old in three years. So, then I have to figure out what age she is right now. And then when I figured that out, and then farther in the question it said, but her brother's two years older than what she is right now. So then I had to add, so then I had to add two to it, which he called 49 and 29.

The analysis confirms that the distinct semantic structure and cognitive complexity of the two tasks directly shaped his problem-solving and strategy choices (see Table 1).

Table 1: Summary of Semantic Structure and Problem Characteristics on Problem-Solving Strategies

Task	Sematic Structure	Key Linguistics Clue	Problem Characteristic	Strategy Selection
Task 1: Book Savings Problem	Compare/ Difference (How many more?)	"How much more"	Two quantities given (22, 15); unknown difference; one-step. Larger minuend explicit (22 > 15) Multiples of 5 embedded (15, 20, 22)	Standard subtraction algorithm; skip counting; backward jumps. Stacking with regrouping. Skip counting and number line reasoning.

Task 2: Age Problem	Change with comparison (Two-step)	"In three years;" "two years more"	Future reference; two-step structure; multiple unknowns	Sequential subtraction then addition. Bar model reasoning

The Use and Integration of Multiple Representations in Subtraction Problems

Across both tasks, the respondent engaged multiple representational forms, showing flexibility in organizing and communicating mathematical reasoning through physical, symbolic, and mental modes.

Task 1. Ini's primary representation was the symbolic/formal notation using the standard algorithm (Discipline specific) because it enabled him to efficiently use the direct subtraction strategy. This representation is visually organized by place value columns, which he felt simplified in the regrouping (borrowing) process and reduced the cognitive load of having to mentally track an imaginary one. He also noted that the convention of placing the larger number on top facilitated the process of taking away. "*I put the one over to make sure that I remember that I already borrowed 1… So, stacking (crossing it to show borrow) makes it easier.*" While engaging with the task, I observed that Ini was using his fingers alongside (see Figure 2). I asked him what he was trying to figure out by doing that.

Ini: 5 + 2, 5 and then I did. And then I was like 1, 2 and then I did 5 + 2 like 5, 6, 7 and then I was a new 7.

Figure 2: Student Using Finger to Compliment His Problem-Solving Process

Using the standard stacking subtraction algorithm, in which digits are crossed out to indicate regrouping, reduced the cognitive demand associated with holding a borrowed value in working memory by externalizing the regrouped quantity on the written record—supporting reasoning that would otherwise need to be mentally maintained when using nonstandard or mental strategies (Fuson, 2003). Also, Ini's integration of finger; a concrete strategy within a formal symbolic procedure aligns with Boulton-Lewis's (1993) observation that analogs like finger counting often support the execution of more abstract operations.

Furthermore, to know Ini's preferred representation, I asked him how he would *explain the task to his friend and what picture or tool he would use to help them understand thereby* shifting the focus of the task cognitive demand from solution execution (solving) to mathematical explanation. His response was "'*A bar model*.' *So, if I like got squared. And they each have 5 tallies. And I gotta make my 15. And then there's my 15. And then I'll say, and then I'll put a plus sign and then make like…"* (see Figure 3).

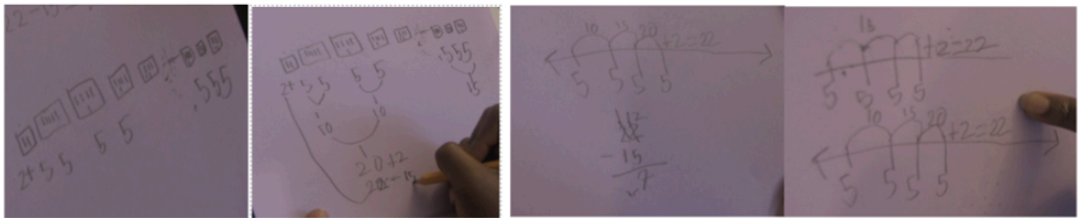

Figure 3: Student Engaging with Various Representations

The bar model (a semi-structured visual analog) was used to show groups of fives composing the whole (22) and then conceptually subtracting the (15) by grouping tallies into units of five and used labels like 5, 5, 5, 5, 2. He connected the whole (22) to its parts through repeated addition/skip counting. The elements (groups of five) made the numbers easier to decompose and manipulate. He was further prompted to represented the problem differently, he used the number line, a discipline-specific visual tool to model skip counting up to 22 and later showed how the number line could represent subtraction by jumping backward from 20 to 15, then adding the remaining two, to find the difference, leading to the result of seven thereby connecting the representation to both additive and subtractive reasoning. These further probe the awareness of representations as communicative tools (doing math to teaching math) and how representation mediates conceptual understanding.

Subsequently, I prompted Ini to recontextualize the task to determine whether his reasoning was driven by the surface story context, underlying semantic structure or if context influences his representational choice. Thus, uncovering the entry point into the problem-solving process.

Interviewer:	So, did the story or the situation make you think about a problem in a certain way? Imagine if this task was like a balloon task and let's say pizza cause that's your favorite, and not buying books, do you think you would have solved it in a different way?
Ini:	Yeah, well, then I would have just made the slices in fractions like that (for Task 1 again).

He drew four whole pizzas, partitioned into five slices each, plus a fifth pizza partitioned into halves, totaling 22 slices (whole Pizza). He then shaded 15 of these slices to model the known savings, visually identifying the seven unshaded slices as the needed amount. This pictorial model (see Figure 4) functioned as a concrete, enactive demonstration of "taking away," translating the abstract numerical comparison into a tangible, part-whole scenario (Boulton-Lewis, 1993).

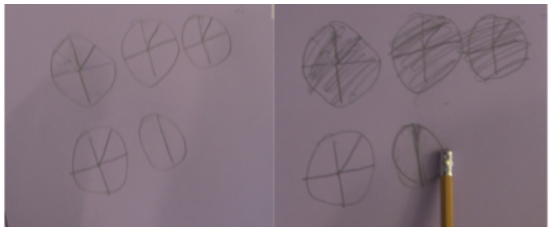

Figure 4: Student Using Picture to Model Fractional Part of Subtraction

Task 2. Ini primarily relied on formal notation (equations) to execute the two steps, labeling the steps "M" and "B" (see Figure 5) and writing corresponding equations (M: 20 – 3 = 27; B: 27 + 2 = 29). His preference for formal notation can be explained by the semantic structure, cognitive complexity, and the problem characteristics of the task, and this direct arithmetic approach (standard procedures) is common once a problem is defined. Research shows that multi-step word problems increase working-memory demands, prompting students to externalize their thinking through symbolic notation to organize and stabilize intermediate results (Soneira et al., 2023; Wang et al., 2016). From a cognitive load perspective (Boulton-Lewis, 1993), noted that formal notation reduces processing demands by allowing the student to offload memory requirements—labeling steps ("M" and "B") and recording equations helps track dependencies between quantities. The two-step characteristics initially constrained Ini's ability to generate alternative visual models.

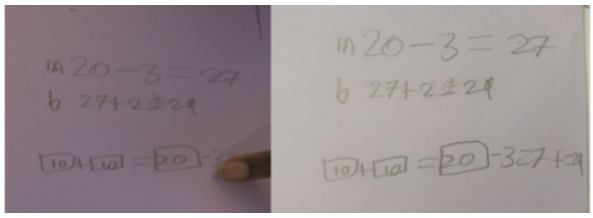

Figure 5: Student Using Bar Model to Show Two-Factor Subtraction

Ini's overall representation choices, as summarized in Table 2, revealed a patterned interplay employed in all three representational categories described in the Boulton-Lewis (1993) model.

Table 2: Student's Use and Integration of Multiple Representations Across Tasks

Boulton-Lewis Representation Category	Representation Used	Task 1: Book Problem	Task 2: Age Problem
Material Strategies (Analogs)	Concrete groupings: finger counting; pictorial analogs (e.g., pizza slices, tallies)	Used	Limited use
Discipline-Specific Representations	Standard subtraction algorithm; symbolic expressions; number. Bar model	Used	Used
Mental / Verbal Strategies	Mental regrouping; verbal explanations; internal tracking of quantities	Used	Used

Discussion

This study examines the problem-solving process of a fourth-grade student using two analytical lenses. It focuses on the semantic structure and problem characteristics of the subtraction tasks, alongside the student's representational choices. Findings indicate that the two tasks grounded in location of the unknown (whether the missing quantity appears as the starting amount, change amount, or difference within the problem structure) shape the student's strategy choice and the representational affordances made available during the problem solving. The

student's initial choice of standard algorithm for subtraction was triggered by the surface-level linguistic cue "how many more," which he interpreted as a direct signal for the minus operation. Also, his ability to identify the minuend and the subtrahend based on the problem characteristics reflects a conceptual understanding of subtraction as a relationship between quantities. This aligns with research highlighting how children's early strategy selection is often cued by salient verbal features before a deeper structural understanding develops (De Corte & Verschaffel, 1987, as cited in Calabrese et al., 2024). However, the student's reliance on a linguistic cue for "minus" underscores the caution raised by Boulton-Lewis's (1993): without explicit instructional support to connect such cue to the underlying mathematical structure of the problem (e.g., the comparison relationship), strategy use may remain superficial.

Furthermore, the problem characteristics strongly shaped the representations the student selected and constructed. For Task 1, the explicit "how many more" linguistic characteristic guided him toward both direct subtraction (standard algorithm) and complementary additive strategies (counting up/skip counting), which he effectively modeled using bar models, number lines, fingers. These types of representations are highly effective because they made the difference perceptible as a visible gap between quantities, enabling the student to leverage the inverse relationship between addition and subtraction. Meanwhile, the need to determine a present value from a future age and then adjust for a relational comparison appeared to privilege formal notation (Symbolic Representation) as a means of keeping track of the steps involved in the second task. Notably, the bar model was the only visual representation he identified as applicable across both tasks. Thus, representations are not neutral supports; they actively shape how students think, the strategies they employ, and how they transition from situational reasoning toward abstraction (Mainali, 2021). At the same time, Boulton-Lewis (1993) cautions that the instructional value of representations depends on their coherence and systematic variation within a small set of tools are more effective for discerning mathematical structure: an overabundance of tools, or representations that are poorly aligned with the task structure, may increase cognitive load and obscure rather than clarify mathematical relationships.

Conclusion

The study highlights how subtle differences in problem structure can shape how students engage with and represent mathematical ideas. As the student tackled different problem types, his shifts in representational forms revealed how semantic structure and problem characteristics influenced active cognition, and the implication for mathematics education is profound. While the student progress toward symbolic fluency, it underscores a central challenge that procedural skill is accompanied by adaptive, relational thinking. This requires a pedagogy that is responsive, discourse-rich, and designed to make the structures of mathematics visible, thereby empowering students to make intelligent and flexible strategy choices across all problem types. Likewise, teachers must deliberately guide students through three distinct pedagogical steps: recognizing the structural foundations of subtraction problems, pairing these structures with appropriate visual or physical models, and utilizing these tools to build efficient mental math skills. However, the absence of physical manipulatives during the interview constrained the student's range of visible strategies, forcing him into symbolic methodologies and obscuring his full problem-solving potential. Consequently, future research may address these gaps. By positioning mathematical representations as a core practice, this research enriches ongoing discussions regarding how elementary students build strategic and adaptive reasoning in word problem solving.

In this study, we focused on preschoolers' noticing, wondering, and posed problems during individual read-aloud sessions. In particular, we share findings for 12 participating preschoolers in two different classrooms with two different picture books. Initial insights highlight that preschoolers' noticings, wonderings, and problems posed emerged from the researcher's prompts as well as on their own. Based on the picture books' contexts and illustrations, preschoolers noticed various mathematical elements: numbers, space, measurement, and geometry. We determined the ways in which these noticings were related to their wonderings and problems posed depending on whether the noticings functioned as problem situations.

Keywords: Early Childhood Education, Instructional Activities and Practices, Number Concepts and Operations, Measurement

Posing problems to solve and using problem solving skills to solve them are important mathematical practices (Kilpatrick, 1987; Siller et al., 2025). Problem posing is generally defined as generating a new problem from a given situation or reformulating a given problem (Silver, 1994). Although problem posing is often overlooked in mathematical explorations, improvements in students' problem posing are associated with better problem-solving ability (Bonotto & Dal Santo, 2015; Cai & Hwang, 2002; English, 1997; Singer & Voica, 2015). As an important practice, research on problem posing is relatively new (Cai et al., 2015). Further, most research attention has focused on third grade through high school students (e.g., Bonotto, 2013, Bonotto & Dal Santo, 2015; Cai, 2003; Ellerton, 1986; English, 1997, 1998; Silver & Cai, 1996; Wilkie, 2024) and college or preservice teachers (e.g., Baumanns & Rott, 2024; Crespo & Sinclair, 2008; Silber & Cai, 2017). Research with children under the age of six is rare (Carmona-Medeiro et al., 2024; Martin-Diaz et al., 2026; Pálmer & van Bommel, 2020) and has not focused specifically on the process of helping young children pose problems.

For preschoolers, play is an important avenue for posing and exploring problems (Fosse et al., 2020; Parks, 2015). Stories can encourage students to try creating new block creations (Casey et al., 2004, 2008) and picture books, specifically, can provide a broad context and allow students to focus on what they notice and wonder mathematically (Hintz & Smith, 2022). Picture books' openness allows preschoolers to play with potential mathematics and is likely to encourage them to create new problems as well (Ginsburg, 2006). Responding to Cai et al.'s (2015) call to better understand how students interpret problem situations to pose problems, we investigate what mathematics preschoolers notice in picture books and how these noticings relate to what they wonder about or problems they pose based on the contexts.

Theoretical Framework

Children's literature is an influential instructional tool that supports children's mathematics learning, interest and mathematical concept development (Young et al., 2018) and mathematical language (Purpura & Reid, 2016), motivates students (Luedtke & Sorvaag, 2018), and links mathematics with children's experiences (Marston & Mulligan, 2012) and emotions (Griffiths & Clyne, 1991). During read-aloud sessions, prompts used by readers are necessary and essential for stimulating their mathematical thinking (Elia et al., 2010). In particular, questioning, giving feedback, and identifying practical applications are crucial for developing strong mathematical skills (Jacobi-Vessels et al., 2014). Hintz and Smith (2022) outlined a process called *open notice and wonder reads* for mathematizing children's picture books, regardless of whether the books have an explicit or implicit mathematical focus. Central to the focus of this instructional move is that children have the space to engage with stories and share their thinking. The teacher stops at predetermined pages that have rich illustrations and invites children to explore them by asking, "What do you notice?" Children might focus on the context and illustrations (Hintz & Smith, 2022). Noticing includes observations that one makes and is used to refer to a momentary shift in focus or a form of attention (Mason, 2003). Therefore, preschoolers' mathematical noticings in picture books could involve spontaneous attention to relevant aspects of visual or narrative elements such as quantities, relationships, shapes, sizes, patterns, etc. They might also focus on situations they consider noteworthy, even if not mathematical.

Next, the teacher encourages children to explore the story and visuals further by prompting, "What do you wonder?" During this process, the teacher records children's thoughts to make them visible. In brief, children's noticing and wondering process provides an opening for them to share their observations and curiosities. This approach also creates a mathematical opportunity for teachers to think about posing problems based on their noticing and wondering in the story (Hintz & Smith, 2022). Likewise, children can turn their noticings and wonderings into problem posing situations, which are the context and data offered to problem posers for generating problems (Cai et al., 2022). Thus, in this study, we used open notice and wonder reads, encouraging preschoolers to mathematize children's literature and build their background knowledge (Crespo & Sinclair, 2008). We then used their noticings and wonderings to encourage the development of new problems (Marston, 2014). Hence, we investigated the following research questions:

1. What do preschoolers notice mathematically in individual read-aloud sessions based on the stories' contexts and illustrations?
2. What do preschoolers wonder and pose problems about mathematically in individual reading aloud sessions?
3. In what ways do preschoolers' noticings correspond to their wonderings and problems posed?

Methodology

Participants and Setting

The data presented in the current study come from a larger qualitative study approved by our university's IRB in which we recruited 23 preschoolers (ages 2.5–5) from four different classrooms at a midwestern preschool in the US. In the larger study, in session one, each classroom participated in a notice and wonder read. Then, in sessions two and three, participants participated in two small-group notice and wonder reads with two new books. In this paper, we focus on results from the final session with 12 preschoolers (ages 3–5) who participated in an

individual notice and wonder read with one of the researchers. All names are pseudonyms. In particular, they listened to one of two picture books: *Ten Apples Up On Top* by Theo. LeSieg (eight preschoolers listened to this one) or *I'm the Biggest Thing in the Ocean* by Kevin Sherry (four preschoolers listened to this one). During the notice and wonder read, the researchers invited each preschooler to share what they noticed and wondered on set pages from the book. The researcher then further probed for what questions they could pose to trick them and gave an example as needed. The researchers modeled wondering and posing problems both in previous sessions and within these individual sessions using language such as, "What do you wonder? What do you want to know more about? What questions do you have? What math questions could you ask to try and trick me?"

Analysis

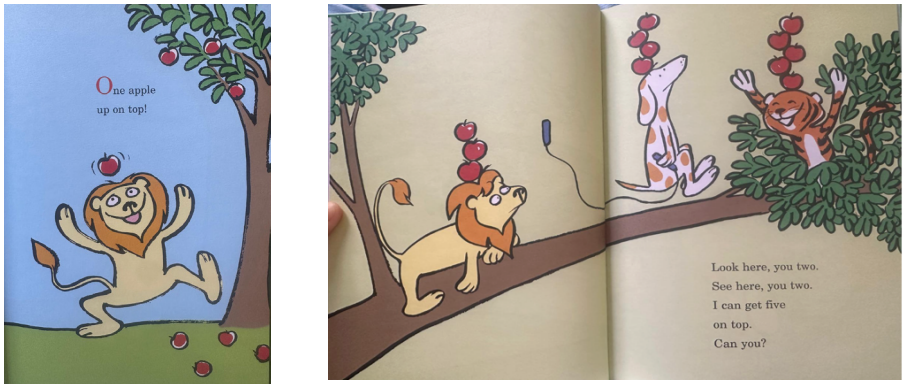
We coded students' responses into the two main categories highlighted by Hintz and Smith (2022): noticing and wondering. However, we split the wondering code into wondering and problems posed. Wonderings were broader than problems (e.g., "Why are there so many apples in that big basket?" versus "How many apples are in the container?"). Under these three main codes, we coded students' responses for their general mathematical domain and wrote descriptors for specific topics within those domains (see Table 1). If the noticings, wonderings, or problems did not relate to mathematics, we noted if they related to the book's context, visuals, or other elements not found in the book. The coding process involved two rounds. First, each researcher coded one of the interview transcripts deductively based on the mathematical domains (or non-mathematical) and the noticings, wonderings, and problems posed. In the second phase, we discussed the codes and refined them collaboratively.

Table 1: Codes For Noticing, Wonderings, and Problems Posed

Codes	Description
Math-Number	Referencing numbers of things
counting	Counting numbers of things
quantity	Talking about more/less
chunks	Identifying chunks of numbers (like subitizing)
addition	Identifying an addition problem with objects
Math-Measurement	Referencing measurement-related aspects
length/height	Talking about how long/small, tall, or wide something is
size	Talking about how generically how big or small something was
time	Talking about how much time something took
weight	Talking about how heavy/light something is
Math-Geometry	Referencing shapes or shape properties
Math-Space/Location	Referencing locations with words such as in, on, near, etc.
Math-Patterns	Referencing patterns
Non-Mathematical	Referencing non-mathematical aspects
visuals	Noticing objects in the visuals not related to mathematics concepts
context	Using the context of the story to notice beyond the page
not related to book	Talking about sticky notes we had on the book

For each book page where we elicited preschoolers' responses, we grouped the noticings and wonderings/problems posed according to each category to look for patterns and to identify which

domains of mathematics were referenced. We also linked wonderings/problems posed with any responses or possible answers preschoolers provided. Finally, we identified whether their wonderings and problems posed arose out of similar noticings or if they were unrelated to what they had been discussing prior to that.



Results

In this section, we present the preschoolers' noticings, wonderings, and problems posed for each book according to mathematical domains and nonmathematical ones. While describing these data, we gave particular attention whether their responses were spontaneous or prompted.

Findings Related to the *Ten Apples Up On Top* Picture Book

Across the eight preschoolers who engaged with *Ten Apples up on Top* during their individual session and the five pages we stopped on, they shared 181 noticings. Of these, 70% were mathematical. Further, they had 32 wonderings and posed 44 mathematics problems. Next, we discuss these further in relation to the mathematical domains they discussed.

Number-related noticings, wonderings, and problems posed. Preschoolers were most likely to have number-related noticings, wonderings, and problems with this story. Sometimes, these noticings occurred in response to the researcher's prompts or sometimes emerged without any prompts. For instance, on the first page we stopped on (see Figure 1a), when the researcher modeled posing the problem, "How many apples do you see on top of the lion?" Waldon answered, "One (apple on the ground)," but then continued to notice, "There are three apples on the tree" and "There are four apples on the floor." Subitizing these three sets of apples was common and sometimes related to their problems posed. For example, on the same page, without prompting, Wiley posed a problem, "How much apples are on the tree?" and immediately answered his own problem as "Three," directly relating his noticing to his problem. Then, he posed another problem, "How much apples are on the ground?" and answered, "Four." The next time we stopped at a page (see Figure 1b), Whitney noticed that the apples on the animals' heads were in counting order. She then asked two non-mathematical questions, so the researcher probed, "Do you have any math questions about this page?" The student then posed the problem, "How much apples are there altogether, if we put 3, 4, 5 all together?" to which she counted to find the answer. Later in the story, the researcher asked Wayne, "If this bird eats one of these apples, how many will the tiger have?" Wayne also answered it by counting them and stated, "Nine."

(a) (b)

Figure 1: (a) First Page and (b) Second Page That Preschoolers Talked About

Space and location noticings, wonderings, and problems posed. Space-related noticing was the next most common and predominantly occurred embedded within number-related noticings rather than as an independent focus. For example, when asked about the first page (see Figure 1a), "What do you notice on this page?" Weston noticed, "Apple *up on* this animal." The preschoolers frequently talked about the location of the apples: "… on the cat," "… on the dog," "… on top," and "… on his head." Related to the second page we stopped on (see Figure 1b), the preschoolers also had space-related wonderings, such as, "Why are they *on* that stick [branch]?" and "Why is the tiger *in* the fruits?" These were also categorized as context-related wonderings. Although space-related noticings emerged as the second most frequent mathematical focus, the preschoolers did not pose space-related problems and did not relate their space-related noticings to their space-related wonderings.

Measurement noticings, wonderings, and problems posed. Measurement-related noticings were less frequent compared to the numerical and space domains. Yet, preschoolers occasionally mentioned length, size, volume, time, and weight, particularly after the researcher's prompts. For instance, on the second page we stopped at, the researcher asked, "How long is the lion's tail?" and Wiley responded to this question stating, "This long (showing the length with his fingers), one of this long." The researcher invited, "Do you have any questions about this page? … You can trick me with any questions." Then, the preschooler posed the question, "How long is the tree?" and he answered his own question, "Five inches." Winnie didn't have any measurement-related noticings, but she posed multiple questions about size: "How big is this tree?", "How big are the branches?", "How big is the doggie?", and "How big are the letters?" Preschoolers posed measurement problems second in frequency to number problems, but in all but the one case mentioned, their measurement problems were not related to their noticings.

Geometry and pattern noticings, wonderings, and problems posed. Geometry-related and pattern-related noticing were least common and only occurred when the researcher asked them, such as, "What shapes do you see on this window?" The only shape mentioned (by two preschoolers) was a square. There weren't any wonderings or problems mentioned, highlighting that this mathematical domain was not a mathematical focus within this book. Further, one student provided a pattern-related noticing on the second page we showed. The student saw the tiger and said, "Orange, black, orange, black, orange, black," describing the pattern with the tiger's stripes.

Non-mathematical noticings, wonderings, and problems posed. Beyond mathematics, preschoolers generally noticed visual elements, naming characters ("It's a tiger and a dog and a lion"), actions ("The lion looks like it's crawling"), emotions ("The cat is angry"), and objects ("There's a fridge") and less frequently made comments about the context, e.g., "Because that's just pretend." Yet, these noticings rarely led to nonmathematical wonderings. The preschoolers wondered about particular aspects of the visuals, such as when Wiley asked, "And why does the dog's tail look like a marshmallow?" On the other hand, Whitney stated her context-related wonder, "How could they reach up with those (long forks)?"

Findings Related to the *I'm the Biggest Thing in the Ocean* Picture Book

Across the four preschoolers who engaged with *I'm the Biggest Thing in the Ocean* during their individual session and the four pages we stopped on, they shared 77 noticings. Of these, 65% were mathematical. Further, they had eight wonderings and posed 10 mathematics problems. Next, we discuss these further in relation to the mathematical domains they discussed.

Number-related noticings, wonderings, and problems posed. As with the previous book,

the preschoolers were most likely to make number-related noticings, and they also posed more number-related problems than those from other domains. On the first page we stopped at (see Figure 2a), the shrimp stood out to the preschoolers, but they all responded in different ways when asked what they noticed. Aria just pointed to the shrimp, using a gesture rather than words; Alfio said, "There's lots of shrimp;" while Alvin immediately started counting them (from 1 to 22). On the other hand, Austin immediately posed the problem, "How many of these are there?" On the third page we stopped on (see Figure 2b), the teeth were prominent to the preschoolers. One of them counted the teeth while another first asked, "How many teeth are there?" and then counted them. Alfio made an interesting comparison observation, "He (whale) has more teeth than him (squid). He (squid) has zero teeth." Of their numerical problems posed, the problems were related to their numerical noticings just over half the time.

(a) (b)

Figure 2: (a) First Page and (b) Second Page That Preschoolers Talked About

Space and location noticings, wonderings, and problems posed. Overall, across the four preschoolers, only two of them referred to location, and that was only when prompted. On a page showing the fish inside the whale, the researcher asked where the other turtles went, and Alvin replied, "Right there." With another student, the researcher asked what was going to happen, and Alfio replied, "Get out." Surprisingly, no other students made comments about the fish being inside the whale (even though they previously saw the fish outside of the whale).

Measurement noticings, wonderings, and problems posed. Across the data, measurement-related noticings were second highest after the numerical ones. From the data coded, the mathematical measurements were related to length and size comparison. For example, on the first page we stopped at (see Figure 2a), the researcher asked if the shrimp were shorter or longer, and Alvin responded, "Long," even though they were smaller than the squid. On the next page we stopped at, the researcher asked if the squid was bigger than the turtles, and the preschooler said, "These (turtles) are bigger than that (squid)" subtly indicating that he was considering the group of turtles as one large group. Similar reasoning might account for why he thought the shrimp were longer than the squid. By the third page we stopped on (see Figure 2b), Austin noticed several aspects related to size and size comparison and posed a measurement problem without prompting. For example, Austin said, "This whale is bigger" and later, "Look how small he (squid) is compared to this (whale)." One of his noticings, "Look how wide it is from my hand," directly related to the problem he posed, "How big his mouth is?" He also posed and answered a question about which tentacle was longest on a previous page.

Geometry and pattern noticings, wonderings, and problems posed. Compared to the apple book, preschoolers noticed some geometry in the book with less prompting. While one student needed prompting to mention shapes, Austin brought up shapes without prompting,

noticing that one of the tentacles made a "circle" (see Figure 2a) and pointing to an eye while describing it as an "oval." On the second page we stopped at, the researcher paused, and Aria pointed to the backs of the turtles and indicated there were "rectangles" on the shells. On the third page we stopped on, Austin posed, "What shape is this when he is like that?" and then answered, "It's half of a circle." Both geometry-related problems that the preschoolers posed were directly related to measurement noticings. Overall, while not a content focus of the story, shapes were more prominent to these preschoolers in this book than for the preschoolers with the apple book.

Non-mathematical noticings, wonderings, and problems posed. As with the apple book, the preschoolers noticed visual elements in the story, naming and describing characters, (e.g., "A whale" and "They're white"), actions ("Yelling"), and objects ("Those are shells") and less frequently made comments about the context, e.g., "If they're (turtles) scared, they will go back in the shell." Even though they made fewer context-related noticings, they wondered about the context more than any other domain except for number. For example, regarding the page in Figure 2b, they wondered, "Is he gonna get, eat them?" In some cases, when asked what they wondered, they phrased their wondering like a prediction, "I think the jellyfish will sting the whale" or "The whale will die." These responses indicate that for some preschoolers, posing questions or wonderings is not as natural as providing statements.

Discussion

Drawing on Hintz and Smith's (2022) notice-and-wonder reads for mathematizing literature, we determined preschoolers' noticings, wonderings, and posed problems during individual read-aloud sessions with two picture books. Across both books, our findings indicated that children stated a range of mathematical noticings, wonderings, and problems along with nonmathematical ones. Not surprisingly, preschoolers were more likely to talk about what they noticed than what they wondered or could pose problems about. However, some students became enthusiastic about posing questions or wonderings and did so spontaneously. Throughout the sessions, researchers' modeling and prompts also supported extending children's noticing into mathematical inquiry (i.e., wondering and posing mathematical problems).

Preschoolers particularly expressed number-related noticings, including numbers, counting, quantities, comparisons, etc., and mentioned number related wonderings, and posed problems. As known, children naturally tend to count (Saxe et al., 1987), and their tendency to focus on numbers might be crucial to their mathematical development (McMullen et al., 2020). Across both books, preschoolers were likely to notice number-related aspects at the same rate. Based on the examples described in the results, the number-related noticings were strongly related to problem posing. In various instances, preschoolers immediately responded to their own problems, revealing a relational cycle of problem posing and/or wondering. Hence, picture books can provide meaningful contexts in which these inherent numerical elements become visible, are supported, and can be used as problem situations. At the same time, preschoolers expressed more mathematical wonderings and posed more problems about numbers with the *Ten Apples Up On Top* book compared to the second book. This result could be due to the explicitness of the number-related context in *Ten Apples Up On Top*.

Furthermore, in our study, preschoolers noticed plenty of space-related elements in the *Ten Apples Up On Top* picture book partly due to the space element being built into the text of apples being *on top* of the animals' heads. Even so, preschoolers generally stated the number-related noticings more than space-related ones, unlike van den Heuvel-Panhuizen and Elia's study (2013) where preschoolers talked about characters coming or going out of the doctor's office and

Elia et al.'s study (2010) where preschoolers talked about position and location. Our choice of which pages we stopped at could account for this difference as children in the other studies talked about each page. The fewer references to space-related elements in *I'm the Biggest Thing in the Ocean* also points to the importance of book choice, as this story does not lend itself to talking about position or location much.

Similar to the spatial findings in the second book, geometry-related elements were limited, largely due to the fact that the books did not have a geometric focus. In fact, there were few shapes that even stand out as being important in the story. Largely, students noticed shapes when prompted to look for them, aside from noticing the prominent eyes or teeth on the ocean creatures in the second book. Likewise, wondering about shapes in terms of the books would not be expected given the focus of the stories.

Regarding measurement, there were elements especially prominent in *I'm the Biggest Thing in the Ocean*, offering a learning environment where preschoolers had a chance to notice diverse measurement-related elements. One of the preschoolers needed prompting to respond to measurement-related ideas; however, two of the others continued talking about measurement after an initial suggestion. In terms of wonderings and problems posed, especially in *Ten Apples Up On Top* picture book, preschoolers' high number of problems and wonderings might be due to the picture book's context and visuals or more elaborate story compared to the second book. These results suggest that further investigating the features of stories in relation to what children notice and wonder would be important. The findings also highlight the significance of picture book selection. Explicit mathematical illustrations (e.g., compositions of shapes) in strategically chosen books by teachers (i.e., books where those mathematical elements in illustrations are important to the story) may better encourage focus on specific mathematical topics and concepts (e.g., geometry, shape composition).

Considering in what ways preschoolers' noticing, wonderings, and posed problems varied, number-related noticings and sometimes their measurement noticings were often related to their wonderings and problems posed. However, their geometry and space-related noticings did not result in problem posing. Again, this is likely due to those areas not being a focus of the stories. Further studies should continue this process with a wider range of stories to better capture the potential of this method for encouraging students to wonder and problem pose. Consistent with the teacher's dialogic approach (Björklund & Palmer, 2020; van den Heuvel-Panhuizen & Elia, 2013), for children to derive meaning from picture books (Björklund & Palmer, 2020), the findings of our study highlighted that the noticing-and-wondering process encouraged children to express their thinking with the researcher's prompts. Further, these results provide important evidence that even preschoolers can pose mathematical problems that are relevant and solvable (Martin-Diaz et al., 2026).

Overall, the findings of our study indicate that picture books provided rich contexts and illustrations integrating various mathematical elements. Concurrently, preschoolers' spontaneous noticings and wonderings were shaped by the researcher's purposeful guidance and prompts or formed independently of it, and some of these noticings served as problem situations. This interaction supports preschoolers' contextual and visual understanding of explicit mathematical understandings and encourages them to pose problems.

yuhangwu@connect.hku.hk

Mathematical learning is often propelled by engaging with others' thinking. Drawing on studies across diverse contexts, including students working with computational agents, students collaborating with peers, and teachers interpreting student thinking, this proposal conceptualizes how mathematical knowledge is modified and enriched when learners take up, coordinate, and extend perspectives that are not their own. We argue that a common cognitive thread is decentering: the mental process of temporarily setting aside one's own thinking to adopt and reason from the perspective of another. Synthesizing findings from two empirical studies, we articulate six cognitive mechanisms of decentering-to-learn, organized into three types: (1) representational, (2) coordinative, and (3) epistemic decentering. We also clarify how decentering is triggered and sustained by interactional conditions in different contexts.

Keywords: Cognition, Learning Theory, Communication

Background and Motivation

Engaging with others' thinking is a powerful driver for mathematical learning (Rasmussen et al., 2020; Webb et al., 2023). Among the many ways learners engage with others' thinking, *decentering*, the mental process of temporarily setting aside one's own thinking to adopt and reason from the perspective of another, is central to this engagement. The construct originates from Piaget's account of *egocentrism* and the developmental emergence of perspective taking. In the Three Mountains Task (Figure 1), children demonstrate egocentrism when they assume that a viewer at Position C can see the same objects they see from Position A (Piaget & Inhelder, 1948/1967). The difficulty lies in remaining bound to one's own viewer-centered reference frame rather than constructing the perspective of others. Related challenges appear in technology-rich mathematics learning, such as Logo geometry, where students are required to adopt the agent's perspectives and make sense of its actions to program effectively (Abelson & diSessa, 1981; Geva & Cohen, 1987).

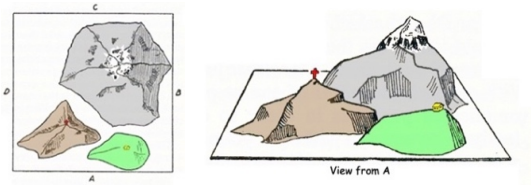

Figure 1: The Three Mountains Task, Reprinted with Permission from Piaget and Inhelder (1967), p. 211

Educational research has extended decentering to characterize peer interaction and student-teacher interaction. Hackenberg (2005) framed teacher decentering as an epistemic disposition, one of orienting to students' ways of operating and "mak[ing] space to see realities that may

differ significantly from their own" (p. 47). Subsequent work has specified the mental actions and observable manifestations of teacher decentering in mathematics classrooms (Baş-Ader & Carlson, 2022; Carlson et al., 2024; Teuscher et al., 2016). Building on this line, Liang (2021, 2025) documented the mathematical consequences of teacher decentering, showing how teachers enrich their personal mathematical knowledge through decentering to student thinking. Complementary constructs appear in science education, where *epistemic empathy* is described as teachers' capacity to understand and appreciate students' cognitive and emotional experiences (Jaber et al., 2018, 2024). Warren (2014) likewise emphasized *perspective taking* as an intellectual component of empathy, alongside empathic concern.

Decentering has also been examined in peer interaction. When students engage in reciprocal construction of understandings with each other, they are poised to incorporate peers' perspectives or argue against perspectives they seek to challenge or reject (Moon et al., 2017; Rasmussen et al., 2020). Together, these studies provide strong evidence that decentering could be productive for learning. However, the field still lacks a systematic conceptualization of how decentering becomes consequential for disciplinary learning, that is, the cognitive mechanisms through which decentering yields knowledge growth.

This proposal addresses this gap by conceptualizing a set of mechanisms of mathematical learning through decentering that cut across educational contexts. We go beyond conceptualizing the decentering act itself to ask: *How do individuals learn mathematically through adopting and coordinating perspectives of others, that is, through decentering*? By foregrounding learning outcomes, we develop a taxonomy of decentering grounded in the kinds of mathematical reorganization that emerge from its enactment.

Throughout, we use "others" broadly to include peers, students, and computational agents. We distinguish the *learner* from the *other*, using *learner* to denote the individual who is engaging in and learning through decentering. When students are the learners, the other may be a peer or a computational agent; when teachers are the learners, the other is typically a student, and we examine how teachers learn by constructing and reasoning with students' perspectives.

Method

We draw on two empirical studies with distinct purposes, populations, and research settings. Study 1 examined primary students' programming-enhanced mathematics learning in Scratch, a block-based programming environment. We asked students to work as a pair because it can offer a supportive environment in which they collaboratively encounter and resolve challenges through interaction (Hannay et al., 2009). For this proposal, we focus on data of one focal pair from eastern China: Seymore (Grade 5) and Selina (Grade 6). Both students had prior experience with Scratch. They completed five hour-long task-based clinical interviews (Goldin, 2000; Hunting, 1997) organized around a series of Scratch-based mathematical tasks. Study 2 involved three in-service mathematics teachers (Mrs. Winn, Mrs. Kelly, and Mrs. Fang) who conducted task-based clinical interviews with students and then reflected on students' mathematical thinking in video-stimulated recall interviews (Calderhead, 1981; Tuckwell, 1980). Mrs. Winn and Mrs. Kelly are Asian American teachers with less than one year of teaching experience; Mrs. Fang is a Chinese teacher with seven years of teaching experience. Mrs. Fang and Mrs. Kelly participated in five interview-reflection cycles, and Mrs. Winn participated in two.

We selected these studies for synthesis because participants enacted different mechanisms of learning through decentering across peer interaction (Study 1), human-agent interaction (Study 1), and student-teacher interaction (Study 2). We conducted thematic analysis of the video data for each case, first identifying critical moments illustrating participants' decentering activities

and then identifying emergent themes that characterized how these activities are generative to their mathematical learning.

Mechanisms of Mathematical Learning Through Decentering

Based on the kind of cognitive work in relation to decentering, we specify six mechanisms organized into three decentering types: (1) representational decentering, (2) coordinative decentering, and (3) epistemic decentering.

Representational Decentering

Representational decentering is concerned with a learner's interpretation of a situation when adopting a different perspective. The enactment of decentering enables the learner to re-interpret the situation such that its properties are distinct from adopting the learner's own perspective.

Shifting reference frames. One mechanism under this type of decentering involves a learner shifting from the observer's reference frame to that of the other (the observed) in order to represent ideas faithful to the other's reference frame. In our work involving human-agent interaction, representational decentering is evident as learners adopt the perspective of a computational agent and represent actions undertaken by the agent in order to understand its behaviors. This decentering act is crucial for the learners to generate effective commands on the agent in order to achieve particular goals. For example, Study 1 addressed a Polygon Task that asks students to use Scratch to draw an equilateral triangle (Figure 2a). Seymore initially struggled to explain why 120 degrees instead of 60 degrees worked to generate an equilateral triangle. It was not until he adopted the sprite's reference frame and modeled the behaviors of the sprite that he realized the turning angle is the external angle of the polygon (Figure 2b). Early work on Logo geometry echoed this finding and revealed students' persistent difficulty with specifying the angle referent of the numerical input (Geva & Cohen, 1987). We view Seymore's learning to be non-trivial and entailed decentering because he had to reconceive the polygon-drawing task to be about movement and turning of the sprite rather than "the shape I want." The external angle thus becomes visible to him when he needs to adopt the sprite's reference frame and model the dynamic generation of the polygon as if he were the sprite.

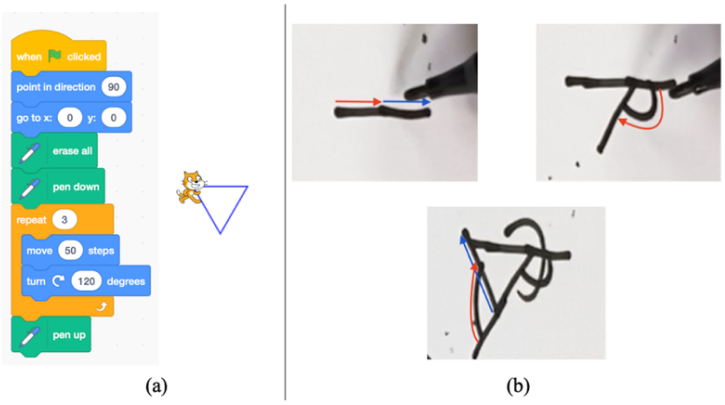

Figure 2: (a) The Normative Solution and (b) Seymore's Work, Reprinted with Permission from Liang et al. (2026), p. 22

Shifting representational systems. Another mechanism of representational decentering is representing the other's perspective with a representational system distinct from that used by the other. This involves the learner internalizing the other's thought and representing it in their own

way. In Study 2, Mrs. Kelly was working with her student, Taylor, on a linear programming task (Figure 3a). Taylor solved the problem with a purely algebraic method (Figure 3b): he first selected a series of value pairs that satisfy the 10,000-square-foot constraint (e.g., 1000–9000, 2000–8000, and 5000–5000) and then calculated the total cost of furnishing for each combination. Eventually, he concluded that 5000–5000 was the best solution because it is "the only place where you are spending all of your money and using up all of your space.

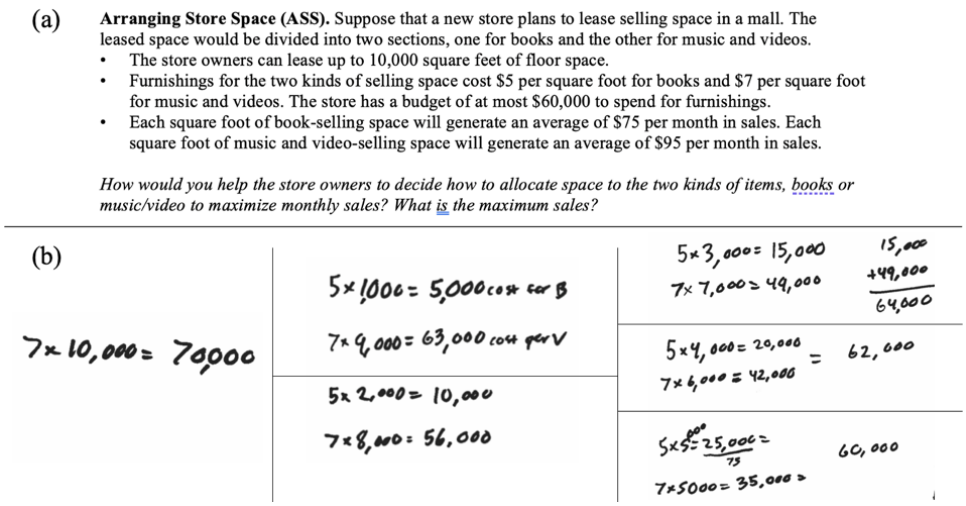

Figure 3: (a) The Linear Programming Task and (b) Taylor's Solution, Reprinted with Permission from Liang (2025), p. 22

When discussing Taylor's thinking in the stimulated recall, Mrs. Kelly contrasted his method with the conventional graphical method. She showed that while the conventional method considers all feasible points in the shaded area in Figure 4a, Taylor's method is "more efficient" because it only considers a subset of feasible solutions (see the segment highlighted in blue in Figure 4b). We view this to be a form of representational decentering because Mrs. Kelly represented Taylor's thinking (a purely algebraic method) with a graphical representation.

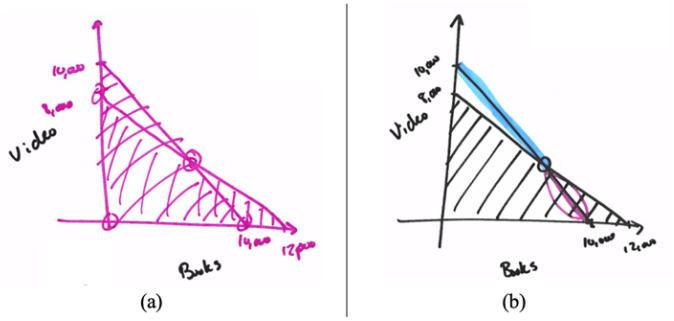

Figure 4: Mrs. Kelly's Graphical Representations of the (a) Conventional Method and (b) Taylor's Method, Reprinted with Permission from Liang (2025), p. 24

In both cases, decentering changes what counts as the relevant description of the situation to the learners. For Seymore and Selina, decentering involves recasting the mathematical object

within the agent's reference frame and reconstructing representations from the agent's perspective. Decentering to the agent's frame reorganizes their interpretation of the mathematical idea under study (e.g., turning angle) and makes certain ideas salient (e.g., exterior angle). For Mrs. Kelly, decentering means introducing a novel representation that makes another's perspective visible and intelligible. In both cases, learning occurs as a result of adopting different representational frames so that others' perspectives become coherent and sensible to the learner.

Coordinative Decentering

Coordinative decentering is concerned about the relationship between multiple perspectives and involves a learner coordinating others' perspectives with their own. The cognitive work may involve comparing, combining, and connecting different perspectives.

Integrating perspectives. One mechanism of coordinative decentering involves a learner integrating elements and aspects of their own thinking with those of another. When the two perspectives entail different strategies, this integration often yields a composite strategy repertoire. In Study 1, as previously mentioned, Seymore used the "turn 120 degrees" block to draw an equilateral triangle. Selina, by contrast, used the "point in direction" block, considering the absolute directional angles for drawing each side. She first input 90 as the initial direction (rightward) and estimated –135 for the second side, but she struggled to determine the third direction that would return the sprite to its starting point and close the shape (Figure 5a). As Seymore engaged with Selina's approach and attempted to support her debugging, he worked to compute the directional angles precisely. He produced the drawing shown in Figure 5b, where he leveraged the 120-degree turning angle to infer that the remaining directional angles should be –30 and –150 degrees (Figure 5c). We interpret this as coordinative decentering by which Seymore not only decentered to Selina's thinking but also coordinated two angle conceptions and reference systems: (a) angle as an absolute direction in Selina's thinking (with upward as 0 degrees), and (b) angle as a relative turn from the current heading in his own thinking.

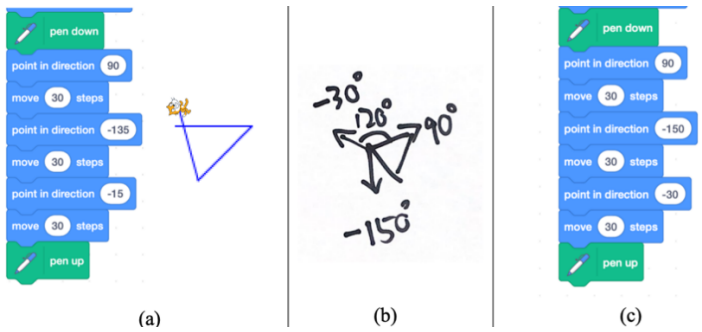

Figure 5: (a) Selina's Solution and (b-c) Seymore's Solution, Reprinted with Permission from Liang et al. (2026), p. 16

Building coherence. This involves constructing a translation between two perspectives and establishing a mapping that explains why both perspectives work and how they relate. In Study 2, Mrs. Winn's students worked on a task on dilation: they were given an image rectangle $A'B'C'D'$ and asked to construct the preimage $ABCD$ with a scale factor of 2.5 from the center of dilation O (Figure 6a). In explaining her own solution, Mrs. Winn represented 2.5 as "two wholes and a half" and emphasized its equivalence to five halves (Figure 6b). She reasoned that because the length OD' is measured as 2 inches, one-half should be 0.4, and thus one "whole" is 0.8. In comparison, Carlee approached the problem by undoing the scale factor: she calculated

$OD = 2 \div 2.5 = 0.8$ and placed Point D at 0.8 inches from O; she also represented "2.5" on the segment by partitioning it into two and a half sections (Figure 6c). In stimulated recall, Mrs. Winn reported that she could not make sense of why division was appropriate and noted that she "should have asked for Carlee's explanation." When prompted to explain, Mrs. Winn invoked the "N (units per group)–M (numbers of groups)–P (product)" model of multiplication/division (Izsák & Beckmann, 2019), mapping the scale factor to the number of groups ($m = 2.5$), the image-center distance to the product ($p = 2$), and the preimage-center distance to units per group ($n = p/m = 0.8$) (Figure 6d). She noted that n is one "whole" and p is equivalent to "taking the whole and enlarging it by 2.5." By coordinating Carlee's division-based method, her own partitioning method, and the N–M–P model, Mrs. Winn constructed a translation between these perspectives that was not initially apparent, and she expressed excitement at making these connections. We interpret this as learning through building coherence because Mrs. Winn reorganized her knowledge so that each account became intelligible in terms of the other, and the meanings for division, partitioning, and dilation became all connected.

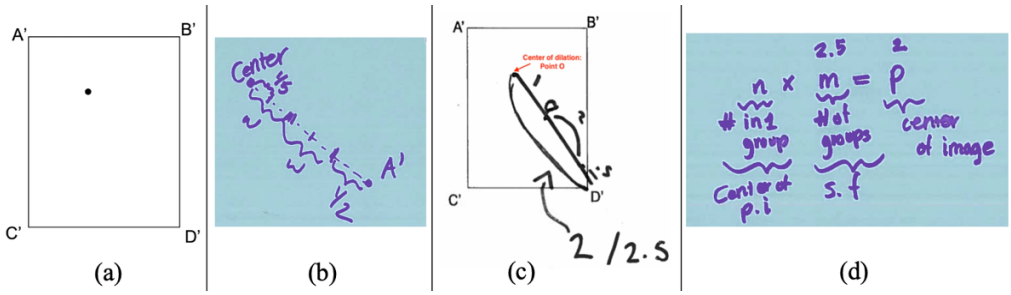

Figure 6: (a) The Dilation Task, (b) Carlee's Work, and (c–d) Mrs. Winn's Work

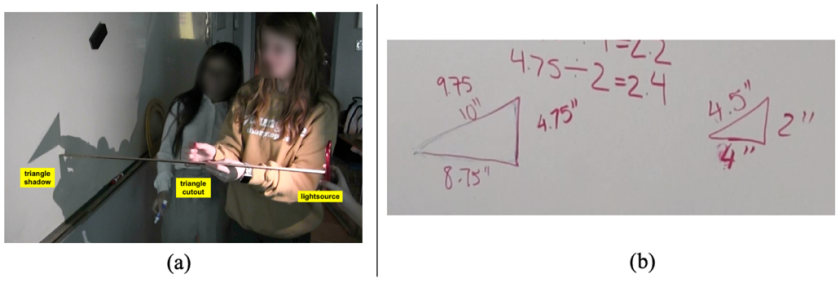
Both integrating perspectives and building coherence are forms of coordinative decentering, but these mechanisms foreground different observable learning outcomes. Integrating perspectives involves incorporating one perspective into another while working within the constraints of the other. Building coherence entails deeper conceptual reorganization such that the perspectives become mutually explanatory—each can be used to interpret, justify, and make sense of the other. In both cases, the common mental act is engaging with others' thinking through coordinating it with additional perspectives and articulating relations among them.

Epistemic Decentering

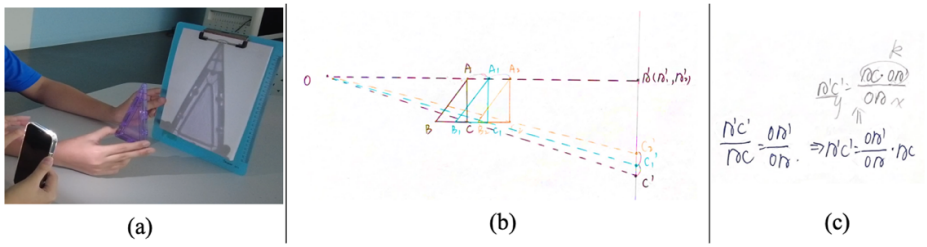


Epistemic decentering refers to decentering that shifts what one takes as assumed, thereby reorganizing one's existing knowledge or generating new knowledge. It concerns the status, grounds, and assumptions of knowledge, for example, how ideas are defined, what is treated as given, and what counts as an adequate explanation.

Clarifying implicit thinking. This mechanism involves making implicit premises, assumptions, definitions, or warrants explicit in light of alternative thinking. Because others may operate with different assumptions, decentering to their perspectives can reveal invisible presuppositions in one's own knowledge. This is especially consequential for teacher learning, since curricular tasks and language often hide definitional choices (e.g., defining similarity in terms of length rather than other quantitative attributes), choices that teachers must surface and clarify in instruction. In Mrs. Winn's case, she worked with her students to create a shadow of a triangular cutout that was "twice as big" as the original (Figure 7a). She traced the outlines of the shadow and the cutout on the whiteboard (Figure 7b), intending to engage the students in a

discussion on the proportional relationship between the dimensions. Before she began, however, Carlee remarked that the shadow looked much bigger than a doubling of the cutout. During stimulated recall, Mrs. Winn realized that Carlee may have been comparing areas rather than lengths, an interpretation under which the shadow can appear more than a doubling even when linear dimensions are scaled by two. Reflecting on this, she noted:

> I never think about area when I think about dilation. I think about dimensions … just take it as a given … I think it goes back to the language, because if you say "something is twice as big as the other," what does that mean? It could mean area … or it could mean ... like the dimensions are twice as big. I think it is just that language is very confusing.



Here, Mrs. Winn was coordinating two competing perspectives of dilation: dilating length versus area. Only through working with students and decentering to Carlee's thinking did she realize that her taken-for-granted conception of dilation-as-length was not trivial but an implicit choice that needed to be made explicit. This episode is epistemic rather than representational or coordinative because the learning hinges on surfacing and revising what is presupposed, that is, which quantitative attribute "twice as big" refers to, and more broadly, what counts as an appropriate basis for multiplicative comparison in dilation contexts. Decentering thus functions as an epistemic cue: encountering the student's perspective exposes what Mrs. Winn had been treating as given and brings previously implicit assumptions in her reasoning into the foreground.

(a) (b)

Figure 7: (a) The Shadow Task and (b) Mrs. Winn's Drawing

Generating new knowledge. Decentering to another's perspective can also prompt learners to revise their initial understanding of a situation, resulting in the generation of new knowledge. In these moments, the learner does not simply adopt the other's view; rather, the other's ideas catalyze new cognitive work that yields insights that go beyond either initial perspective.

(a) (b) (c)

Figure 8: (a) The Triangle Shadow Task and (b–c) Mrs. Fang's Work

In Study 2, Mrs. Fang worked with her student Jasper to explore the relationship between the dimensions of a triangle and those of its shadow (Figure 8a). Jasper proposed that if the triangle

moves away from the light for equal amounts, the side length of the shadow would increase by equal amounts. This claim intrigued Mrs. Fang, but she was uncertain how to respond and not convinced that a linear relationship was warranted. During the stimulated-recall interview, she took Jasper's claim as a hypothesis to test, producing Figure 8b to simulate the situation and showing that the relationship is inverse proportional and thus nonlinear (Figure 8c). Mrs. Fang's decentering is evident in her sustained effort to pursue Jasper's proposed relationship and to formalize it mathematically. We interpret this as epistemic decentering because Jasper's perspective reorganized Mrs. Fang's understanding of what counts as a plausible underlying relationship in the situation and motivated her to construct a newly warranted explanation.

Discussion and Conclusion

In summary, we identify six mechanisms of learning through decentering, organized into three types: representational, coordinative, and epistemic decentering. These mechanisms link decentering to diverse learning outcomes (e.g., shifting frames of reference and representational systems, coordinating methods and ideas, foregrounding implicit assumptions). These mechanisms are not mutually exclusive: a single episode can involve multiple forms of decentering. For example, Mrs. Kelly's case can be characterized as both shifting representational systems and building coherence as she related Taylor's method to a conventional graphical method. Likewise, when directional-angle and turning-angle perspectives are coordinated, the work of integrating perspectives also positioned Seymore to recognize their equivalence, supporting building coherence. Treating these mechanisms as overlapping enables us to capture different dimensions of a learning situation and supports multiple, complementary accounts of how learning unfolds through decentering.

Our contribution builds on prior research that has established the importance of decentering and perspective taking and offers a proof-of-concept that decentering can be theorized not only as a stance or interactional feature, but also as a set of cognitive mechanisms through which disciplinary learning becomes possible. We also extend existing accounts by shedding light on what mechanisms are at play in certain interactional contexts, specifying interactional conditions that make decentering more likely to be triggered, sustained, and consequential.

In human–agent contexts, representational decentering is often central, with many activities requiring learners to adopt an agent's frame to generate effective commands. We note that such opportunities are occasioned in task designs, in which the "other" is intentionally engineered to constrain and redirect learners' reasoning. The emergence of AI agents further motivates design work on feedback and prompts that foster productive decentering of AI agents' perspectives.

In peer interaction, decentering is frequently occasioned by multiple strategies, making coordinative decentering salient as students compare, test, and reconcile different methods. Productive peer talk can also support epistemic decentering as students press for warrants and surface hidden assumptions. Future research on peer interaction can continue to adopt the lens of decentering to investigate the productive role of peer decentering in learning.

In student–teacher interaction, asymmetric roles and epistemic responsibility often foreground building coherence (coordinative decentering), as teachers interpret students' informal accounts while connecting them to disciplinary explanations, and can also support epistemic decentering, as teachers notice differences in languages, referents, definitions, and criteria across student thinking and curriculum. This points to the need for design-based research in teacher education to develop learning opportunities and structural support for teachers' learning through decentering.

SECOND GRADERS' MOVES THROUGH EMERGENT MATHEMATICAL MODELING LEVELS IN BLOCK PUZZLE GAMEPLAY

Ayse Ozturk
Old Dominion University
aozturk@odu.edu

This study examines how second graders' gameplay behaviors reflect their progression through emergent modelling levels during block puzzle play. Guided by two research questions, it explores the types of moves students make and how these moves align with four emergent modelling levels. Data were collected through six video-recorded interview sessions with twelve students working in pairs. Thematic analysis was used to identify and categorize students' moves, which were then mapped onto the emergent modeling framework. Findings revealed two main move types: exploratory moves, most common at the situational level, and strategic moves, which appeared primarily at the referential and general levels, with a few at the formal level. This study extends emergent modeling to a digital context and provides insights into how gameplay can support early mathematical reasoning.

Keywords: Elementary Students, Emergent Modeling, Mathematical Reasoning, Gameplay, Digital Tool, Student Moves

Understanding how children develop mathematical reasoning is a critical area of research in mathematics education (Laurens et al., 2017). Early experiences that engage children in problem-solving and reasoning with mathematical concepts provide a foundation for later success in formal mathematics learning (Bang et al. 2023; Cobb et al. 2021). These early opportunities for mathematical reasoning are essential, as they support children in building connections between intuitive ideas and more abstract mathematical concepts (Sarama & Clements, 2009).

Puzzle-based digital games have increasingly been recognised as valuable tools for supporting this developmental trajectory (Bang et al. 2023; Polinsky et al. 2022). Such games provide interactive, low-stakes environments in which children can experiment, strategise, and reflect on their decisions, fostering mathematical agency and exploration (Bane et al., 2023; Bofferding & Aqazade, 2023). These environments also make children's reasoning visible, offering researchers and educators rich opportunities to observe how spatial understanding evolves through digital play and interaction (Kim et al., 2017). Despite the widespread integration of digital technologies in primary classrooms (Bang et al. 2023; Hussein et al. 2022), there remains limited research on how specific gameplay behaviours connect to children's reasoning processes, particularly in relation to reasoning during mathematical modeling (Sengupta et al., 2014).

Research in early-grade mathematical modeling shows that engaging children in activities such as identifying patterns (English, 2003), using numbers to represent mathematical objects (Lesh et al., 2013), exploring two- and three-dimensional shapes and figures (Stohlman et al. 2016), and applying optimization strategies on a grid area (Ozturk, 2025) can significantly support the development of spatial reasoning. While these studies highlight promising pathways for fostering modeling competencies, much of this work has been carried out using hands-on materials rather than technology-based environments (Stohlmann & Albarracín, 2016). More recently, studies have begun to explore how digital tools can enhance modeling opportunities for young learners (Hussein et al., 2022; Sengupta et al., 2014). However, there remains a need for a deeper understanding of how children's strategies in digital gameplay contexts can reflect and

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

promote their progression in mathematical modeling (English, 2021; Stohlmann and Albarracín 2016).

This study addresses this gap by investigating how second graders' moves during block puzzle gameplay reflect their progression through emergent modeling levels. Emergent modeling, as described by Gravemeijer (1999), provides a framework for tracing the development of students' reasoning as they move from intuitive, context-bound strategies toward generalized and formal mathematical reasoning. This framework has been instrumental in examining how learners shift from informal problem-solving to formal mathematical representations (Van den Heuvel-Panhuizen, 2003). By adapting emergent modeling approach to a digital gameplay context, this study connects two growing areas of research: early mathematical reasoning and technology-enhanced learning environments. The present study is guided by two research questions: *(1) What kinds of moves do second graders make while engaging in block puzzle gameplay? and (2) How can these moves be related to the levels of emergent modeling?* These questions are designed to illuminate how young learners' in-game moves can serve as indicators of their mathematical reasoning.

By situating gameplay moves within the emergent modeling approach, this research contributes to the field in two keyways. First, it extends the application of the emergent modeling framework to digital learning environments, offering methodological insights for researchers examining mathematical reasoning through technology-mediated tasks. Second, it provides educators with a nuanced understanding of how different types of gameplay moves—ranging from exploratory to strategic—may reflect distinct stages of mathematical reasoning. In doing so, this work responds to calls for context-rich, developmentally appropriate approaches to early mathematics education that bridge children's informal reasoning with the more formal practices of mathematical modeling in elementary classrooms (English, 2021).

The Framework: Emergent Modeling and Its Four Levels of Activity

Emergent modeling refers to the process through which students' context-specific strategies and representations develop into general mathematical tools for reasoning (Gravemeijer, 2007). At its core, an emergent model is not simply given to students but rather arises from their own activity. Initially, students work with informal representations that are closely connected to the task at hand. Over time, these representations are reorganized and generalized, evolving from a *model-of* the situation into a *model-for* broader mathematical reasoning (Doorman & Gravemeijer, 2009). The aim of this process is to support students in developing increasingly sophisticated ways of reasoning (Cobb et al. 2021; Gravemeijer 1999). In this sense, an emergent model is both a product of students' activity and a catalyst for moving from context-bound strategies towards formal mathematical understanding (Van den Heuvel-Panhuizen, 2003).

The theoretical foundations of emergent modeling lie in Realistic Mathematics Education (RME), which conceptualizes mathematics as a constructive human activity rather than a fixed body of knowledge to be transmitted (Freudenthal 1991; Verschaffel et al. 1994). RME emphasises that students should engage with problems that are experientially real, whether these stem from everyday life, play, or meaningful classroom contexts (Laurens et al., 2017). Within this framework, emergent modeling serves as a design heuristic for bridging the gap between students' informal reasoning and formal mathematical concepts (Doorman & Gravemeijer 2009; Van den Heuvel-Panhuizen, 2003).

Gravemeijer (1999) articulated four levels of activity through which emergent modeling progresses. At the *situational level*, students' reasoning remains tied to the immediate problem context. At the *referential level*, their representations begin to function as *models of* the situation,

capturing mathematical relationships within the context. Progressing to the *general level*, these representations evolve into *models for* mathematical reasoning, enabling their application across different contexts. Finally, at the *formal level*, students' activity is characterized by the use of symbols and abstract reasoning that are no longer dependent upon the original situation. These levels informed our analysis in this study. We adopted this framework as it offers a systematic lens through which to examine how second graders' moves during gameplay demonstrate transitions from intuitive, context-bound strategies towards increasingly generalized mathematical reasoning.

Research Setting, Participants and The Game App

This exploratory qualitative study was conducted with 12 second-grade students (seven girls and five boys) who were enrolled in an after-school program at a public primary school in the Midwestern United States. The students worked in pairs during a single 45-minute interview session. Each pair was interviewed individually and provided with a touchscreen iPad to engage with the free *Block Puzzle Game App*. The iPad was connected to a projector, allowing the gameplay to be displayed on a larger screen. Each interview was video recorded from an angle that captured both the students' interactions and their moves during gameplay.

The game requires players to arrange block shapes, each composed of unit squares, onto an 8×8 grid with the aim of forming complete horizontal or vertical lines. At the beginning of each turn, three new blocks appear at the bottom of the grid, and players must strategically place them within the available spaces. Whenever a line of eight consecutive squares is completed, it disappears, enabling players to earn points and create additional space for new blocks. Success in the game depends on players' ability to anticipate future moves, position the given set of blocks effectively, and maximize the number of cleared lines. The game concludes once no remaining blocks can be placed on the grid. Importantly, it is age-appropriate for second graders and aligns with their curricular standards, which highlight reasoning with shapes, partitioning rectangles into equal squares, analyzing attributes, and exploring equal groups of objects as a foundation for multiplication.

Data Collection, Coding and Analysis

No formal instructions were provided to the students, as the purpose of the study was to examine how their gameplay moves illustrated progression through emergent modeling levels. A total of six interviews were conducted, each structured into three phases. During the initial 10 minutes, students engaged in free play, allowing them to explore the app's features and familiarize themselves with the objectives of the game. The subsequent 25 minutes focused on strategic play, during which students began to formulate and apply strategies, identify patterns, and practice spatial reasoning. The final 10 minutes comprised a reflection phase, where students responded to prompts such as, "What was difficult or easy about the game?" and "How did you decide your next move?" These reflective questions were designed to elicit students' reasoning about their decision-making processes and strategies. Although the participants were familiar with puzzle games and educational applications from their regular mathematics lessons, none had prior experience with the specific app used in this study.

The data comprised four and a half hours of video-recorded interviews, which were transcribed and analyzed alongside students' move data saved within the app. In this study, a *move* is defined as a single, observable action or decision made by students during gameplay, accompanied by the corresponding verbalization or reasoning that explains that action. The analysis focused on categorizing the types of moves students employed during gameplay and

examining how these moves aligned with the levels of emergent modeling. Specifically, the process of students placing the three newly generated blocks during each turn, thereby creating a new scenario for completing a horizontal or vertical line on the grid, was conceptualized as an *emergent model.*

To address the first research question, we employed thematic analysis (Clarke & Braun, 2013) to systematically identify and categorize the types of moves students made during gameplay. Two researchers repeatedly reviewed the transcripts of gameplay sessions to establish familiarity with the data, after which initial codes were generated inductively to capture distinct types of moves (e.g., trying out fits). To address the second research question, these coded moves were then interpreted through the emergent modeling framework. Within this framework, students' moves with blocks were categorized as emergent models and situated within specific modeling levels. Moves were assigned to levels based on the nature of students' reasoning and the extent to which their decisions remained tied to the immediate gameplay context or were generalized into broader mathematical ideas. In this way, thematic analysis produced a coding scheme of students' moves, which was subsequently mapped onto four levels to capture students' progression in emergent modeling.

To strengthen the trustworthiness of the coding and analysis, the initial coding scheme was developed through close readings of all transcripts and iterative discussions between the two researchers over approximately four hours. The codes were then collaboratively refined before moving to the second phase of analysis, in which mapping students' moves onto the four framework levels required an additional three hours. Throughout the process, the researchers met regularly to apply the coding scheme across the full dataset, ensuring consistent application of coding and enhancing the reliability of the findings.

Findings and Discussion

Our analysis identified two overarching types of moves—exploratory and strategic—with exploratory moves comprising five subcategories and strategic moves comprising six subcategories. We first describe the characteristics of these two types of moves before examining how they occur across the modeling levels. Tables and illustrative examples are provided to highlight distinctions between exploratory and strategic moves within the same modeling level.

Exploratory moves reflect students' efforts to test, notice, and compare possibilities in the moment. We identified five subcategories of these moves. *Trying Out Fits* involves experimenting with multiple placements before settling on one, as when a student drags an L-shaped block around the board while saying, "it could go here… no, maybe here." *Observing Line Effects* occurs when students notice the immediate outcome of completing a line and attempt to reproduce it, such as realising that "it disappears!" when a line is cleared. In *Counting*, students use numerical reasoning to check spatial fit, for example, "This one is three long—one, two, three—so it fits in this row." *Recognition of Patterns* reflects students' awareness of recurring shapes or effects in the grid, as when they identify a "T-shape." *Comparison* entails weighing immediate alternatives without long-term planning, such as deciding, "If I put it here, there's more space left than if I put it over there."

Strategic moves reflect students' forward-looking decisions aimed at managing space and optimizing future possibilities on the grid. We identified six subcategories of these moves. *Prioritising Corners* refers to positioning blocks in the corners to keep multiple pathways open, as one student noted, "I'll tuck it in the corner, so we still have room on the board." *Keeping the Centre Clean* reflects efforts to preserve open space for larger pieces, with students' reasoning, "Don't put it there! We need the middle open for the big piece."

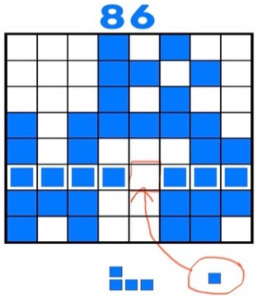
In *Managing Junk Blocks*, students proactively place oversized blocks to avoid unfillable gaps, saying, "Let's get rid of this big block now before it messes us up later." *Watching Out for Single Squares* involves monitoring one-square spaces that are difficult to place and can block future moves, as a student said, "Wait, that will leave just one little square, and nothing fits there." *Checking Horizontal and Vertical Lines Simultaneously* refers to placing blocks to complete rows and columns at the same time, which maximises points and opens up more space on the grid, as one student said, "If we put it here, it clears both across and down!" *Delaying Placement (Resisting the Immediate Fit)* demonstrates students' willingness to forego an immediate fit to preserve better long-term options, as captured in the reasoning, "This T-shape fits here, but let's save that space for the little one square."

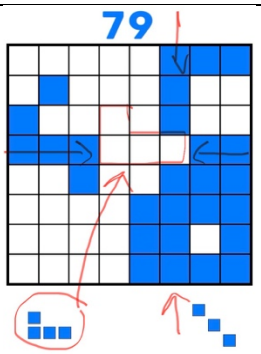
Occurrences of Moves Across the Emergent Modeling Levels

Analysis of the 138 identified moves revealed that students engaged more frequently in exploratory activity (84 moves) than in strategic activity (54 moves). Table 1 illustrates the distribution of these moves across the four emergent modeling levels, highlighting that exploratory moves primarily occurred at the situational level, while strategic moves were concentrated at the referential and general levels, with only a few extending into the formal level.

Table 1: Types of Moves and Their Frequencies of Occurrence at Modeling Levels

Moves (Total: 138)	Levels of Emerging Modeling			
	Situational Level	Referential Level (Model-of)	General Level (Model-for)	Formal Level
Exploratory Moves (84)	63	21	-	-
Strategic Moves (54)	-	39	13	2





Exploratory moves were the most observed at the situational level**,** where students relied on immediate fits on the grid, and to a lesser extent at the referential level, where they began to notice and describe emerging block patterns within the game. No exploratory moves were observed at the general or formal levels, indicating that this type of activity remained closely tied to the task setting. In contrast, strategic moves showed a wider distribution across levels. Mostly observed at the referential level, where students developed strategies directly connected to their observations of the game environment, such as avoiding single-square gaps or placing blocks in corners. Thirteen strategic moves were observed at the general level, reflecting the use of broader strategies such as delaying placement to optimize future options. Notably, only two strategic moves were observed at the formal level**,** where students abstracted beyond the game context to articulate foundational general principles of reasoning with shapes.

Example of Exploratory Versus Strategic Move at the Referential Level

At the Referential level, students begin to develop *model-of* their activity within the task setting. At this stage, they notice, describe, and interpret block patterns or game effects that emerge from their moves. While their reasoning remains closely connected to the concrete situation, they start to form representations of how the game functions. In contrast to the situational level, where students simply place blocks wherever they fit, those at the referential level begin to articulate observations about the game's rules and outcomes—for instance,

recognising that certain shapes consistently fit into similar spaces. Table 2 illustrates this distinction by providing examples of one exploratory move and one strategic move, together with the corresponding emergent models and students' dialogues, demonstrating how these two types of moves differ even within the same modeling level.

Table 2: Example Students' Moves, Emergent Models, and Students' Dialogues

Referential Level (Models-of)	Sub-Category of Moves	Emergent Model	Students' Dialogues
Exploratory Move	Observing Line Effects		A: "Let's move that little one [the circled block] here." B: "See, it [the row] disappeared!"
Strategic Move	Checking Horizontal and Vertical Lines		C: "Look over that space. If I place it [the circled block] here, it will make the lines on both ways disappear." D: "Yes, we need to keep the center empty."

Observing Line Effects, as an exploratory move at the referential level, shows that students are beginning to notice and describe the immediate outcomes of their moves, such as recognizing when completed rows disappear. While this demonstrates growing awareness, the focus remains on interpreting visible outcomes rather than planning ahead. In contrast, *Checking Horizontal and Vertical Lines Simultaneously,* as a strategic move, reflects a more advanced form of reasoning. Here, students not only notice patterns but also apply this reasoning to make forward-looking decisions during gameplay. As illustrated in Table 2, a single move that clears multiple lines at once indicates deeper engagement with the game's structure, where students' observations begin to guide decision-making and the development of emerging strategies. This comparison highlights how growing awareness of block patterns and game outcomes informs more deliberate and purposeful moves.

Conclusion and Implications

This study examined how second graders' moves during block puzzle gameplay reflect their progression through four emergent modeling levels. The findings revealed that exploratory moves were dominant at the situational level, whereas strategic moves emerged more prominently at the referential and general levels. These patterns demonstrate how gameplay can

serve as a rich context for observing the transition from informal problem-solving to early forms of mathematical abstraction. This progression echoes prior literature on emergent modeling, emphasizing the importance of context-based tasks that allow mathematical reasoning to develop organically from students' actions (Doorman & Gravemeijer 2009; Gravemeijer 1999; Van den Heuvel-Panhuizen, 2003).

The implications of this study extend to both research and practice. From a research perspective, and in line with Sengupta et al.'s (2014) findings, our results highlight the value of using the digital puzzle game as a methodological tool for examining young children's mathematical reasoning during modeling activity. By mapping students' gameplay moves onto emergent modeling levels, researchers can gain deeper insights into how specific contexts support or constrain the development of higher-order reasoning (Cobb et al., 2021). From a practical standpoint, teachers can utilise such activities to actively engage students while simultaneously making their mathematical reasoning visible, thereby providing opportunities for formative assessment (Doorman & Gravemeijer, 2009). Future studies could build on these findings by exploring how different game designs or instructional supports shape young children's progression through emergent modeling levels, deepening our understanding of how they build mathematical knowledge through play.

TOWARDS DEVELOPING A HUMANISTIC-COGNITIVE FRAMEWORK FOR MATHEMATICAL MODELING: THE CASE OF GWEN AND ARYA

Lily Roth
Utah State University
lily.roth@usu.edu

Sindura Kularajan
Utah State University
sindura.kularajan@usu.edu

The cognitive perspective of mathematical modeling cannot be viewed in isolation from the influence of students' personal experiences, beliefs, and emotions. Hence, we developed a set of competencies as part of a (re)humanizing mathematical modeling framework. Through a qualitative single-case study approach, we analyzed one pair of pre-service teachers' modeling work for the presence of (re)humanizing modeling competencies (RMC) and cognitive modeling competencies (CMC). Findings were that personal connections and expose and engage injustice were most prevalent in systematizing and validating. In contrast, RMC were least prevalent in working mathematically, interpreting, and mathematizing. From our results, we introduce a humanistic-cognitive framework, showcasing humanistic ways of reasoning as an integral part of students' modeling processes, especially when reasoning within the real-world domain.

Keywords: Modeling; Cognition; Affect, Emotions, Beliefs, and Attitudes

When situated in students' personal, cultural, and social context, mathematical modeling (modeling hereafter) can (re)humanize mathematics (Gutiérrez, 2018). Through humanizing mathematics, we can positively shift students' mathematical disposition and support their development of "mathematical power"—the confidence, competence, and agency to engage in complex mathematical tasks—and critical ability to "read the world" (Gutstein, 2003, p. 44–46).

To understand how modeling can be humanizing, it is necessary to examine when and how humanistic ways of reasoning emerge in students' thinking, the extent to which they align with cognitive modeling competencies (CMC), and the ways they influence students' modeling decisions. Within the modeling education field, modeling cycles have been designed to examine student's cognitive thinking (e.g., Borromeo-Ferri, 2007). As such, they do not explicitly account for affective or contextual dimensions of learning, despite the interrelationship between affect, cognition, and modeling (Chamberlin, 2019). Thus, it is imperative to view students as embodied thinkers—individuals whose cognitive processes are shaped by their emotions, personal experiences, and social contexts (Bandura, 1986; 1999)—as a holistic perspective will lead to insights that can better support students' modeling sense-making.

The goal of this paper is to present our conceptualization of (re)humanizing modeling competencies (RMC) and to examine the interplay between humanistic ways of reasoning and modelers' cognition. We seek to answer *how do (re)humanizing modeling competencies emerge and shape students' cognitive modeling competencies during modeling?* Based on the modeling work of one pair of pre-service teachers (PSTs), we propose a humanistic-cognitive framework. This framework extends existing cognitive modeling perspectives and cycles by integrating the affective and contextual dimensions into the modeling process.

Empirical and Theoretical Background

In this report, we position our work as a humanistic-cognitive perspective of modeling. Drawing inspiration from Bandura's (2007) socio-cognitive theory, we operationalize the humanistic-cognitive perspective on modeling as modelers' personal factors (e.g., cognitive and affective factors) and contextual factors working together to construct mathematical

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

representations for real-world situations. In this way, we define modeling as the cognitive *and* affective processes involved in constructing a mathematical representation for a given context (i.e., task or situation). The cognitive component of modeling is informed by theories from the cognitive perspective on modeling (e.g., Kaiser, 2017). The humanistic component of modeling is informed by theories from rehumanizing mathematics, social justice-oriented modeling, and culturally oriented modeling (e.g., Gutiérrez, 2018; Jung & Magiera, 2021; Rosa & Orey, 2010).

Cognitive Perspective on Modeling

Within the cognitive perspective on modeling, the process of modeling is schematically depicted by modeling cycles. A typical modeling cycle consists of CMC that connect one stage of model construction to another. According to Blum and Leiß's (2007, p. 225–226), a modeler *understands* the given real situation, engages in *systematizing* efforts to construct a "real model," applies mathematical knowledge and tools during *mathematization*, *works mathematically* to arrive at a "mathematical result," *interprets* this result to produce contextualized "real results," and *validates* the results against real-world constraints.

The cognitive perspective on modeling has mostly involved investigating students' cognitive strategies as they construct and validate their models. In particular, research has mainly focused on documenting students' modeling routes (Borromeo-Ferri, 2007), investigating the blockages students experience while modeling (Jankvist & Niss, 2020; Klock & Siller, 2020; Stillman et al., 2010), analyzing the CMC elicited as students engage in modeling tasks (Czocher, 2016; Czocher, 2018), and examining how students' reason quantitatively as they developed mathematical models of real-world scenarios (Kularajan et al., 2024; Czocher et al., 2022). More recently, Wickstrom and Jung (2024) developed Modeling Decision Maps as a tool to analyze how K-8 pre-service teachers "constructed and refined" their models (p. 182). While research on students' thinking during modeling has yielded robust descriptive and, at times, explanatory frameworks for students' modeling activities, these accounts typically focus on cognitive processes. This is due to existing frameworks not being designed to capture affective and contextual dimensions. Hence, there is a need to integrate cognitive and humanistic domains (e.g., affect) within modeling cycles to develop authentic and comprehensive explanatory accounts of why a student might have engaged in a certain modeling decision.

Humanizing Perspective on Modeling

Frameworks that humanize mathematics situate modeling within social justice or cultural contexts, such as Aguirre et al.'s (2019) social justice and modeling cycle or Rosa and Orey's (2010) ethnomodeling diagram. Across these approaches, students have been observed to draw on their "ways of thinking" as they engage in CMC, connecting mathematics to their personal experiences, cultural knowledge, and world understanding (Anhalt et al., 2018, p. 321).

For instance, in an adaptation of the Flint Water Task (Aguirre et al., 2019), Flavin and Hwang (2024) tasked their PSTs to consider the food and water needs of Flint children. The authors observed that the cultural and educational backgrounds of PSTs impacted their modeling approaches and decisions. They found that U.S. PSTs calculated bottle sizes with ounces while their Korean counterparts used litres. They also found that Korean PSTs assumed 365 days when estimating the number of schools, with one group considering the Chinese Lunar calendar, while U.S. PSTs estimated either 110 or 180 days after accounting for vacation days. Kaygısız and Şenel (2023) found that understanding and interpreting competencies could be attributed to a students' ability to associate the task with prior knowledge and previous experiences. This influenced their achievement in attaining the desired CMC level during a model eliciting activity in the context of planting a field. These works reveal how a students' background and prior

knowledge are important contributors to their engagement of modeling tasks, highlighting modeling as a reflective and highly cognitive experience.

Influenced by the humanizing perspective on modeling, we propose a (re)humanizing mathematical modeling perspective, which extends the cognitive perspective on modeling to include affective and contextual dimensions. The (re)humanizing modeling perspective values and encourages students to freely express and use their full selves in mathematics through engaging in (re)humanizing modeling competencies (RMC). We use the term "rehumanizing" to pay homage to Gutiérrez's (2018) call for rehumanizing mathematics. RMC refers to students' ability to draw upon their emotions, attitudes, beliefs (affective), and social and situational (contextual) factors while de-contextualizing the real-world situation (i.e., transitioning from the real-world domain to mathematical domain) and re-contextualizing their mathematical results (i.e., transitioning from the mathematical domain to the real-world domain). We operationalize RMC as consisting of the following facets:

- *Personal connections*: students leverage their personal experiences while modeling due to the mathematics being situated in their personal context.
- *Emotions:* students experience mathematics beyond just the cognitive process but also as an experience where they can draw from themselves as living, feeling bodies (e.g., emotion, intuition) while engaging in mathematical reasoning and thinking.
- *Self-reflexivity:* students reflect on their own perspectives and biases during modeling, thereby fostering awareness of how doing mathematics is influenced by their identities.
- *Expose and engage injustice*: students critically examine social, cultural, and environmental injustices at macro- and micro-levels, thereby building empathy and empowering students to see mathematics as a tool for advocating change.
- *Collaborative sense-making*: students construct knowledge through integrating multiple perspectives and knowledge systems in a community-oriented modeling approach.

Methods

Research Design

We followed a case study research design (Yin, 2009) to explore how RMC inform CMC. Data for this study were drawn from a larger project in which two pairs of PSTs engaged in seven task-based cognitive interviews designed to investigate how their modeling-oriented noticing informs their modeling strategies (Kularajan et al., 2026). This illustrative, explorative analysis uses Gwen and Arya's work on the Hospital Task.

The Case: Gwen and Arya and the Hospital Task

The PSTs. The participants consisted of Gwen and Arya, two elementary PSTs from a public university in the Western United States. They were recruited from a mathematics content course. We chose Gwen and Arya's work on the Hospital Task as (i) our PSTs were familiar with the geographical location of the task context—an important part of modeling of the task—and (ii) we hypothesized that consideration of "best" would allow for RMC to emerge. Moreover, these PSTs were comfortable vocalizing their thoughts and experiences as they constructed and reflected on their model, making this case a meaningful selection for providing empirical evidence regarding the interplay of RMC and CMC.

The Hospital Task. The Hospital Task (Zbiek & Connor, 2006) was presented in two scenarios. In Scenario 1, the PSTs determined the best location for a high-powered hospital that serves Boise, Idaho; Helena, Montana; and Salt Lake City, Utah (see Figure 1). In Scenario 2,

the PSTs were given census data (see Figure 2) and again asked to determine the best location for a hospital. PSTs' work on the task lasted 33 minutes and 22 seconds.

> Boise (Idaho), Helena (Montana), and Salt Lake City (Utah) are three large cities in the northwestern part of the United States. The map shows the locations of the three cities as well as other large cities in the area. Determine the best location for a high-powered hospital.

Figure 1: The Hospital Task (Abridged Version)

What if the additional information is also given to you:

City	Census
Boise	232,000
Salt Lake City	199,000
Helena	32,000

Figure 2: Population of the Cities Given 13 Minutes into the Task

Data Analysis

The transcribed interview was analyzed using MAXQDA 2024 (Verbi Software, 2021). The unit of analysis was segments of text (e.g., single or multiple utterances) that conveyed a single idea. For analyzing the CMC, we used a deductive coding procedure based on a prior framework (see Czocher, 2016). This included using sub-codes (e.g., making assumptions, writing math representations) for identifying CMC of *understanding, systematizing, mathematizing, working mathematically, interpreting,* and *validating.* For coding the RMC, we coded instances related to the RMC facets, described previously. We then used inductive strategies to identify student actions that belong under each RMC (i.e., sub-themes). Table 1 shows this analytical framework.

Table 1: (re)Humanizing Modeling Competencies with Sub-themes

Sub-theme	Definition
Personal connections	
Drawing on lived experiences	Students reference *firsthand* stories or acknowledge the absence of such experiences while constructing and reasoning about their model.
Drawing on learned knowledge	Students reference *acquired* knowledge through *secondary sources* or acknowledge the absence of such knowledge while constructing and reasoning about their model.
Emotions	
Expressing affect	Students express emotions (e.g., frustration, excitement, curiosity, uncertainty) while constructing and reasoning about their model.
Intuitive decision making	Students make decisions or draw conclusions based on their intuition or gut instinct. This is often done fast and emotionally with little regard for logic (for more information, see Kahneman, 2011).

Self-reflexivity	
Emotional reflexivity	Students reflect on how their emotions influence their modeling approaches and decisions.
Drawing on internal beliefs	Students may explicitly or implicitly express using their personal values, ethical beliefs, or principles as reasons that influenced their decisions, approaches, and interpretations.
Expose and engage injustice	
Ethical consideration	Students propose and reflect on approaches, decisions, or solutions based on introspection Examples of ethical principles that could be considered include fairness, justice, and equity.
Data consideration	Students consider biases in the data, mathematics, or situation and describe how the model accounts for or addresses such injustices.
Collaborative sense-making	
Asking questions	Students engage one another by asking questions that promote reflection, dialogue, and critical thinking to support the construction and refinement of a model.
Supporting dialogue	Students support and validate each other's thoughts. Examples include using affirmative language or building on one another's ideas.

In both analysis process, the first author (L. R.) completed the initial coding. This was then reviewed by the second author (S. K.). Discrepancies in the coding were noted; afterwards, both authors met and discussed each code individually until a 100% intercoder agreement was reached. We used MAXQDA's quantizing feature to generate code frequencies and corresponding percentages. We used the Code Relations Browser to identify co-occurrences between CMC and RMC.

Findings

Analysis revealed that the most frequent CMC were systematizing (11.8%) and validating (21.8%). For RMC, they were sense-making (15.8%), personal connections (10.9%), and expose and engage injustice (10.9%). The five most co-occurrences were: validating and collaborative sense-making (19.4%), validating and personal connections (12.9%), systematizing and collaborative sense-making (12.2%), validating and expose and engage injustice (10.8%), and systematizing and personal connection (9.3%). The least frequent co-occurrences include any RMC with working mathematically (0.7%), interpreting (5.8%), and mathematizing (6.5%). Due to space constraints, we illustrate on two co-occurrence episodes.

PSTs Embraced Personal Connections as They Simplified the Model

Personal connections with systematizing occurred 13 times, accounting for 9.3% of code co-occurrences.

In Scenario 1, the PSTs were asked to determine the best location for a hospital. After reading the task, Gwen initially suggested Pocatello as the best location. She commented, "it's the biggest town kind of in between all of them [and] it's kind of close to this water source too. So, you could use that for power for the power grid. I'm sure they have a dam somewhere." This was agreed by Arya, leading the pair to "box that one [i.e., Pocatello]." Here, systematizing was identified four times with Gwen as she noted the non-existence of numerical information,

estimated the size of Pocatello, commented on a water source as an important consideration, and drew a box around a potential answer. Her certainty of the presence of a dam reflects her background knowledge that a dam is connected to a power source, contributing to the personal connections theme. These considerations led the PSTs identifying Pocatello as an initial location.

As the pair progressed in the task, they began measuring the distance between towns, finding Rexburg to be about two inches from each city. In considering Rexburg, Arya introduced additional parameters, such as driving time and the curviness of the road. For drive time, Gwen commented, "I have no idea", while Arya remarked, "I know from Logan to Rexburg, it's about three-ish hours, … So, what is Logan from Salt Lake?" Gwen then used the reference point mentioned by Arya to estimate that "Logan from Salt Lake is like an hour and a half." Here, systematizing was identified three times and personal connections twice. While Gwen did not have experience with this drive, Arya's familiarity assisted the pair in estimating the drive time from Logan to Salt Lake. Thus, the PSTs integrated their real-life experience to approximate distance, reinforcing the importance of personal connections for systematizing decisions.

In Scenario 2, the PSTs were given population data of the cities (see Figure 2). Based on this new information, the pair engaged in the following conversation:

> Gwen: My first thought again goes to Pocatello because it's closer to Boise… and it's also still close-ish to Salt Lake City and all that. A part of me wants to go a little bit closer to Boise, but at the same time, I don't know how big of towns Twin Falls and Blackfoot are. I've never been…
>
> Arya: Blackfoot's small. I mean, most towns in Idaho are pretty small.

This exchange highlights how lived (or lack of lived) experience shaped PSTs' modeling decisions. Gwen's uncertainty about the size of Twin Falls and Blackfoot due to not having been to those places limited her ability to refine their model; she had to rely on her co-modeler's insights. Arya possessed the necessary background, recalling Idaho's town as small. This guided the pair's decision not to consider Blackfoot as a location for a hospital. Through these examples, we illustrated how drawing on personal connections was integral in systematizing the situation model. PSTs' personal connections informed their thinking as they made decisions (e.g., ruling out certain locations), estimated values (e.g., driving time), and identified real-world considerations for modeling parameters (e.g., power source).

PSTs Exposed and Engaged Injustice as They Validated the Model

Expose and engage injustice with validating occurred 15 times, accounting for 10.8% of code co-occurrences.

In Scenario 1, at a first glance, Gwen suggested finding an equidistant location. This approach, we interpret, highlights the inherent consideration of equity. In other words, we suggest Gwen's inclination for using equidistance reflected her implicit belief that a shared hospital means placing it in a central position so that there would be equal travel distance between any city. This, she thought, would ensure a fair solution. PSTs, therefore, showed how justice ideals (i.e., sharing, accessibility)—whether explicitly or implicitly stated—influence modeling decisions (i.e., focusing on equidistance). Below, Gwen explained their reasoning as:

> Gwen: Just the general idea of sharing these three cities is sharing this, so it should be of equal use to all of them ideally … So, if they're assuming that they're all putting in the same time and resources to this, they all want to have equal access to it, I'm guessing.

In Scenario 2, PSTs integrated more social justice perspectives as they shifted their thinking towards considering human needs. They determined that "we still want it pretty close to all, so it's still accessible, but maybe just closer to Boise." Gwen justified their decision to choose Boise by stating, "with the populations, I'd adjust it to be just a little bit closer to the places that have higher populations" because "places with the higher populations are probably going to have a higher amount of medical emergencies." The PSTs no longer focused on equidistance as described in Scenario 1 but began exploring and using "population ratios" as a determining factor. Ultimately, after considering population and other "humanizing" factors (see Figure 3), Pocatello was chosen for the hospital in Scenario 2. The PSTs reasoned Pocatello as being closer to Boise and Salt Lake (cities with higher populations) but more accessible to the people of Helena than Twin Falls. Here, PSTs engaged with justice issues for validating their models through considering city populations.

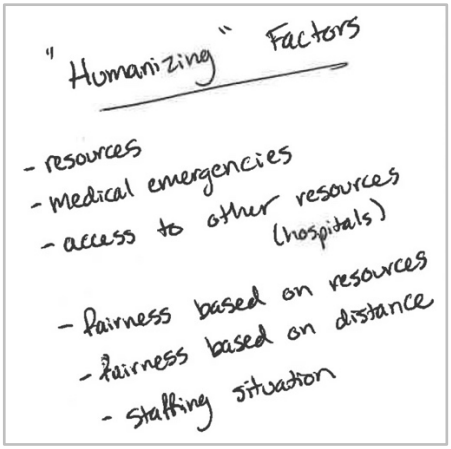

Figure 3: PSTs' "Humanizing" Factors

Even after formulating a solution for the hospital placement, RMC continued to emerge as the PSTs reflected on whether their answer addressed ethical considerations. For example, Arya introduced the idea that "maybe Boise already has a pretty big hospital, so maybe they don't need it as much. Helena is more in need." This statement illustrates an important purpose of (re)humanizing mathematical modeling, which is to challenge assumptions and re-evaluate solutions within broader justice contexts. An example of this is presented in the excerpt below:

Gwen: Okay. So, if I followed the actual, the math, then it would say, okay, seven times closer to Boise would be right there, which I mean, theoretically makes sense. But then, if you're taking into account the people, Helena still has a lot of people that need help. So, think of all the medical emergencies and the people who could die on the way because of the distance.

Arya: It's a hospital for all of them.

This exchange illustrates how the PSTs raised ethical concerns as well as inherent questions that are important when engaging with justice issues, such as: *Who benefits from this decision*? *Who is excluded*? and *What are the trade-offs of prioritizing one outcome over another*? Although Helena and Montana have a smaller population, the PSTs recognized that everyone should have access to a hospital. This led them to grapple with and consider how equity, fairness, and the needs of people could be represented in their model.

Through these examples of validating their model, Gwen and Arya moved away from relying on numerical calculations to determine a solution. Instead, they began looking at modeling through an ethical lens. The PSTs reflected on real-world justice issues and used those concerns in their modeling (e.g., travel distance, population). Moreover, their collaboration revealed an awareness of how different modeling choices can impact communities, thereby exposing and engaging injustice. As Gwen eloquently stated, "there's a big difference between the mathematically correct way of making sense versus the ethically just way."

Discussion and Conclusions

Gwen and Arya demonstrated that cognitive and humanistic ways of reasoning can occur in modeling. Based on our findings, we propose a Humanistic-Cognitive Modeling Framework, developed from iterative analysis of the PSTs' modeling activity and the systematic interactions observed between RMC and CMC. This framework emphasizes student thinking as multilayered. By integrating multiple dimensions—cognitive, affective, and social—into student thinking, we position students as complex individuals with thoughts, emotions, values, and beliefs that play an instrumental role in their modeling-oriented thinking.

In this framework, students enter the beginning phases of modeling (i.e., *understanding, systematizing*) by drawing from their lived experiences and knowledge. This is often done through questioning and refining results based on their perception of the world. Thus, personal connections impact modeling decisions and, therefore, students' engagement with CMC. In adding personal connections, we contribute to a more holistic view and understanding of student thinking while modeling. Expose and engage injustice is placed at the end of the modeling process (usually, *validating*). Our PSTs not only asked whether their solutions were reasonable but also reflected on how their answer could impact certain populations and communities. They were exposing and engaging injustice throughout their modeling, but particularly while validating. Our framework highlights expose and engage injustice as an influencing factor in how students validate their thinking.

Our study has implications for research and education. For the modeling education field, our study has two contributions. First, we proposed, developed, and tested the feasibility of an analytical framework for identifying RMC. This can be used by researchers to develop comprehensive accounts of students' modeling activities. We have ensured its feasibility by providing detailed definition of (re)humanizing mathematical modeling and their sub-themes to support the identification and categorization of RMC. For education, this framework can help educators recognize that modeling can support both cognitive and affect competencies simultaneously—an insight that could potentially lead to more purposeful and integrated modeling implementation (e.g., social justice, culture-based).

We recognize that our study has limitations. The framework used to describe RMC may not consider all possible humanistic elements. While the elements were informed by literature and emerged from iterative analysis of our data, it is also constrained by those. Investigating RMC in a different research setting may yield different outcomes. Moreover, the modeling task used in this case study was local and therefore, contextually familiar to the students. This familiarity means that our study cannot make conjectures about how RMC may appear in tasks that are not local to students. However, the existence of feasibility, as demonstrated by our analysis, is sufficient for theoretical adaptations and modifications. The strength of the framework can be evaluated by testing it against a larger dataset to gain more insights into the prevalence and relationships between RMC and CMC. Additionally, future research could investigate whether tasks explicitly designed with RMC influence the co-occurrences of RMC and CMC.

In this work, we have shared our reconceptualization of the modeling competencies to include not just *what* students do mathematically (i.e., CMC) but *why* they do it (i.e., RMC). The re(humanizing) mathematical modeling perspective is not intended to capture all modes of humanistic reasoning, but it is intended to be an analytic lens for identifying RMC within CMC. Our theory development, although incremental, is a significant step towards understanding the cognitive and humanistic domains of modeling and their integration. We call for continued research to develop approaches that view modelers' mathematical work through a comprehensive lens, where modelers' personal experience plays an active role in model construction and interpretation. An integrated approach like this can lead to a shift in how modeling is conceived and implemented within the modeling education field.

This systematic review investigates how preservice teachers (PSTs) experience the integration of computational thinking (CT) and math. Across 27 studies, most research appears outside math education journals despite 50% being math-related courses. The review shows structural differences in where PSTs encounter CT: elementary PSTs in math methods and Tech/CS courses and secondary PSTs in math content courses. This points to the need for mathematics education researchers to more intentionally shape PST's CT experiences.

Keywords: Computational Thinking, Preservice Teacher Education, Computing and Coding

Computational thinking (CT) has become a central focus in contemporary educational reform as countries worldwide integrate it into K-12 curricula (Bocconi et al., 2022; Hsu et al., 2019). Research indicates that purposeful CT integration can deepen mathematical understanding and contribute to students' developing identities as mathematical thinkers (Weintrop et al., 2022; Mills et al., 2024), though the potential of this relationship remains only partially explored (Li et al., 2019). Because PSTs rarely encounter CT in their preparation, they need meaningful opportunities to engage with CT themselves to understand what it is and how it can support mathematical thinking in the classroom (Waterman et al., 2020). Most research on CT in the context of K-12 education focuses on K-12 students and practicing teachers. In this systematic literature review, we investigate what is known about how preservice teachers learn to integrate CT and mathematics by answering the following research questions: *RQ1:* Where is research on the integration of CT and mathematics in preservice teacher education being published, and are there differences between elements of CT emphasized based on the journal area? *RQ2:* How do documented approaches in integrating CT and mathematics into PST preparation programs align or differ across grade level preparation and course context?

Theoretical Perspectives

CT is generally understood as a set of thinking practices that support information processing and problem solving across a variety of contexts, with or without computers (Cansu & Cansu, 2019; Navarro & de Sousa, 2023; Palop et al., 2024). Researchers operationalize CT as a set of interdependent cognitive and representational practices. Some of the most common practices associated with CT across the literature include *decomposition*: (breaking complex problems into smaller manageable parts), *abstraction* (identifying essential aspects of the problem and reformulating it), *pattern recognition* (identifying trends, similarities or repeated structures in data or problems), *algorithmic thinking* (creating step-by-step procedures, instructions to solve a problem), *debugging* (testing solutions to find errors and improve performance or validating),

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

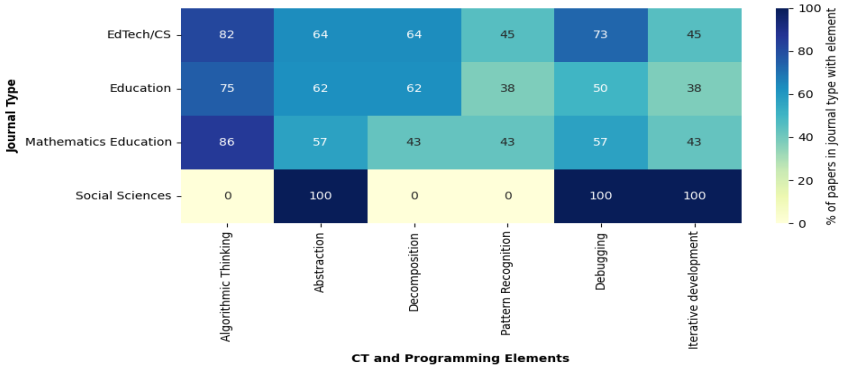
and *iterative development* (refining through repeated improvements; Kallia et al., 2021; Sherwood et al., 2024; Shute et al., 2017; Lehman, 2025; Tang, 2020). This literature review draws on Weintrop et al. (2022) and distinguishes between CT (pattern recognition, abstraction, decomposition, and algorithms) and programming skills (iterative development and debugging).

Methods

We constructed search strings using keywords from four categories where one keyword from each group had to be found within the title or abstract: teachers (*teacher**), mathematics (*math**), computational thinking (*coding, programming, computing*, or CS*) and coursework (experiment*, classroom*, course*, or intervention*). Searches were conducted in EBSCO Host, Web of Science, JSTOR, Supplemental Education Index, and Sage Journals during September 2025 and results were limited to peer-reviewed articles published in English or Turkish since 2006, aligning with Wing's (2006) seminal paper on CT. Any duplicate papers were removed, and this resulted in 4507 papers. All search results were exported to Rayyan for screening and management. The screening process occurred in three stages: initial title screening to remove duplicates and irrelevant items (3435 articles), abstract screening according to the inclusion and exclusion criteria which is ongoing (58 articles), and from that set a full-text review to determine final eligibility (27 articles to date). For each included study, we extracted journal focus, research questions, geographic information, grade band, course context, CT and programming elements, computing environments, and content domain. For clarity, content domains were grouped into number/quantity, algebra/functions, geometry, and data/statistics which included measurement.

Results

The 27 studies included in this analysis were located within five different journal types. The distribution of studies across journal categories were educational technology and computer science journals (11 studies), general education journals (8 studies), mathematics education journals (7 studies), and social science journals (1 study). These numbers suggest that roughly 25% of the published work on integrating CT and mathematics appears in education journals in comparison to the 40% for EdTech/CS journals. The missing conversation from mathematics education was also seen in the research questions of each article, as most focused on the affective elements of the integration, computational skills, integration into lesson planning, or other areas. Only one article had a research question that centered on the mathematical learning of the students and how CT could bring about a better mathematical modeling understanding for PSTs.



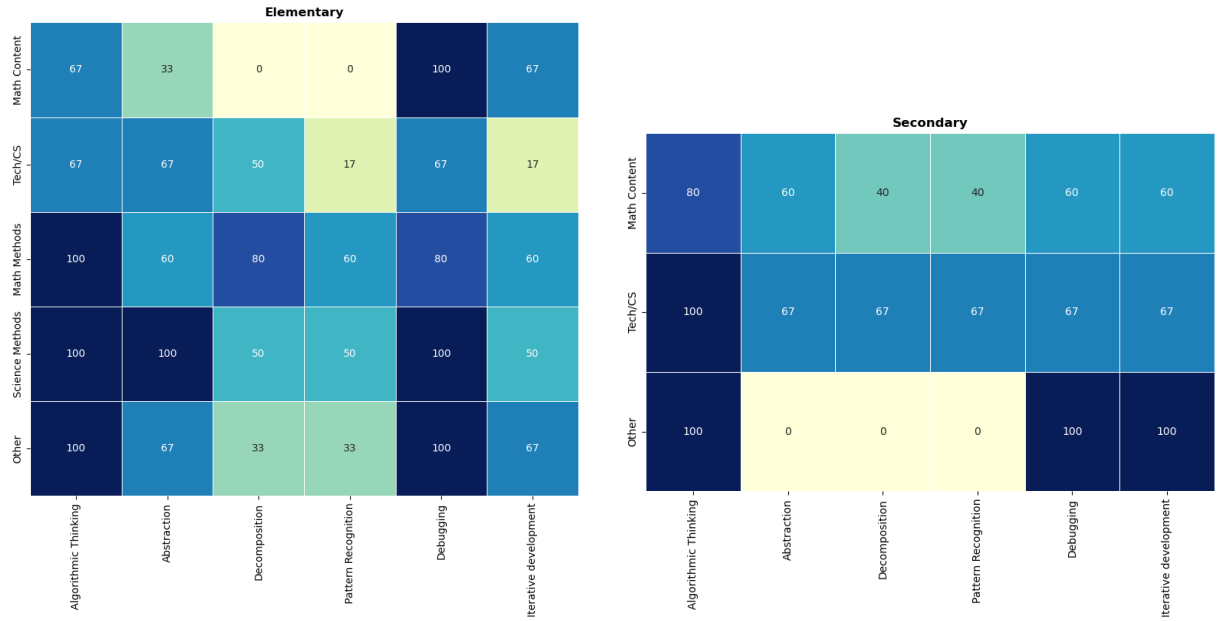


Figure 1: Percentage of Papers within Journal Types that Include Each Computational Thinking and Programming Element, with Values Normed within Journal Type

Table 1: The Distribution of Where CT and Mathematics are Integrated in PST Education, Split by Grade Band and Course Type

	Math Content	Math Methods	Science Methods	Tech/CS	Other
Elementary	3	5	3	6	3
Middle	1	2	0	3	0
Secondary	5	0	0	3	1

Figure 1 displays the percentage of each journal type that includes the specific CT and programming elements described within the theoretical framing. EdTech/CS journals had a broad distribution of CT elements, and a high percentage of studies included algorithmic thinking (82%), debugging (73%), abstraction (64%), and decomposition (64%). Similarly, education had a broad distribution across these four elements, but slightly lower frequencies. Mathematics education journals had the strongest emphasis on algorithmic thinking, which appeared in 86% of studies, yet only 43% of articles referenced decomposition and pattern recognition. Across all journals algorithmic thinking was the most consistently represented CT element.

(a) (b)

Figure 2: Percentage of Articles in Each Course Context that Addressed Specific CT and Programming Elements at the (a) Elementary and (b) Secondary Grade Bands

Mathematics content, mathematics methods, science methods, and Tech/CS courses were the main CT math integration courses (Table 1). At the elementary and middle grade level, most studies were situated in math methods and Tech/CS courses with fewer studies in math content courses. Notably, there were no reported secondary methods courses with this integration. Rather, secondary PSTs primarily encountered integration in math content courses, followed by Tech/CS. The mathematical domains represented also varied by grade band. Elementary studies

were concentrated in geometry (n = 8) and data/statistics (n = 5), with smaller numbers in number and quantity (n = 4) and algebra/functions (n = 3). Middle-grades studies were limited overall but appeared in algebra/functions (n = 2) and geometry (n = 2). Secondary integration spanned all domains, with geometry (n = 4) and data/statistics (n = 3) most prevalent. Although there was integration across PST grade bands, Figure 2 shows that which elements of CT or programming were emphasized split by course context and grade band. Notably elementary math content courses did not have a documented focus on decomposition or pattern recognition, but all emphasized debugging. In comparison, elementary math methods courses had a more balanced distribution of CT elements. Within secondary math content courses, decomposition and pattern recognition were the least mentioned elements of CT and the programming foci of debugging and iterative development were of greater emphasis.

Discussion and Conclusion

Despite PSTs most commonly encountering the intentional integration of CT and math in their math content and methods courses, most of the research is occurring outside of mathematics education journals. Further, the absence of work is not isolated to journal focus but also in the very research questions asked. Only one of 27 studies centered PST mathematical learning and understanding in comparison to typical programming skills or affective elements. If PSTs don't have the chance to center CT as a mathematical sense-making tool or explicit focus on CT supporting mathematical thinking, then early conceptions of CT may solely emphasize how to code or procedural steps rather than mathematical processes such as abstraction, decomposition, and pattern recognition. This could position CT as something tangential to math rather than as a set of practices which reveal structure and deepen conceptual understanding in math.

Structural patterns across course types and grade bands further bring this noticing to light. Elementary PSTs most often encounter CT through math methods and Tech/CS courses, yet in math content courses they primarily experience programming practices such as debugging, with little documented emphasis on decomposition or pattern recognition, which are two practices tightly aligned with mathematical thinking. Secondary PSTs, in contrast, encounter CT almost exclusively within math content courses, but with no documented integration in secondary mathematics methods courses. This means that many future secondary teachers may never have opportunities to develop pedagogical content knowledge to bring CT into math classrooms. Across all grade bands, algorithmic thinking dominated the reported CT elements. While algorithmic thinking is important, its overwhelming emphasis raises concerns that CT math integration may be framed primarily as procedural or solution driven rather than exploratory or sensemaking. This could lead to narrow views of what CT is and what it can offer to mathematics learning.

Together, all these patterns highlight an urgent need for mathematics education researchers and teacher educators to engage more centrally in shaping how PSTs come to understand CT. If CT is to play a meaningful role in mathematics instruction, the mathematics education community must contribute research that examines how CT supports mathematical reasoning, conceptual understanding, modeling, and problem solving. This includes designing and studying learning experiences that foreground the CT elements aligned with mathematical practices, and investigating how PSTs' mathematical understandings as well as their beliefs, identities, and instructional commitments shift when CT is presented not merely as coding, but as a way of engaging with mathematics.

OBSERVING THE TRANSITION FROM EMPIRICAL EVIDENCE TO CONJECTURE IN A DGS ENVIRONMENT

Dana C. Cox
Miami University

Suzanne R. Harper
Miami University
Suzanne.Harper@MiamiOH.edu

This study investigates the boundary between empirical observation and conjecture formulation using dynamic geometry software. Employing a paired think-aloud protocol and screencasting technology, the researchers captured authentic, non-linear mathematical reasoning in a classroom setting. Findings suggest that existing frameworks for inductive reasoning are too linear; the authors propose expanding the model to include "messy" but productive stages such as attempted validation, conjecture rejection, and attempted justification. Ultimately, the study highlights how screencasting captures the essential, non-linear reasoning typically lost in final mathematical products.

Keywords: Reasoning and Proof, Geometry and Spatial Reasoning, Technology

In a collegiate course on mathematical problem solving with technology, we ask our students to explore mathematics with dynamic geometry software (DGS). They use sketches to conduct empirical experiments with geometric objects to explore patterns, pursue conjectures, and test the verity of claims. We routinely ask, "under what conditions might something like this happen?"

As students engage with tasks, we have observed the tipping point where enough empirical evidence accumulates and a conjecture emerges. This boundary is clearly demarcated in the literature (cf. Cañadas & Castro, 2007) and warrants more attention. Specifically, we focus on the way *thinking aloud in action,* where the language is messy, hesitant, and full of contradictions (Maine & Čermáková, 2023) supports the conjecturing process. In a classroom, moments of pattern-finding and where conjectures emerge are fleeting and often hidden within a non-linear path of mathematical behavior and creativity.

Historically, reasoning and process has been documented by Piagetian-style clinical interviews (Cañadas & Castro, 2007) or think-alouds (e.g., Schoenfeld, 1985). Ericsson & Simon (1998) claim that for a think-aloud protocol to be valid, the subject must perform the task (such as a math problem) without trying to explain or justify their actions to the researcher. It is rare, but possible to study the formation of conjectures in a classroom or small group setting. Maine & Čermáková (2023) video recorded and transcribed whole-class and small group conversations in elementary classrooms and were able to capture the moment a child pivots from a vague observation to a specific conjecture. Here, researchers are not a direct audience for the classroom actions of explanation or justification, though they still lurk with a camera as a proxy.

Screencasting offers additional insulation between the participant and the researcher. Cox et al. (2018) tested the potential of screencasting as a tool to capture small group problem solving and found it was capable of capturing moments of authentic creativity within the context of the mathematics classroom. The combination of recording on-screen behavior and verbalized narration enabled the researchers to preserve the authenticity of student reasoning within a classroom culture.

In this study, we used a paired think-aloud structure inside a classroom where students are working within a DGS environment. DGS has been shown to provide feedback to users and encourage iterative design (Laborde et al., 2006). We sought to use the DGS environment as a collaborative work tool, provoking conversation and enabling in-the-moment tweaks and edits,

giving immediate access to the results (Beatty & Geiger, 2010). So, supported within a DGS environment and using screencasting technology, we asked, (1) What reasoning is present at the boundary between observing and organizing particular cases and formulating conjectures when working in a DGS environment? and (2) What are the potentials and limitations of using screencasting to better understand this boundary in a DGS environment?

Theoretical Framework

Stylianides (2008) defines a conjecture as "a reasoned hypothesis about a general mathematical relation based on incomplete evidence," (p.11). This definition encapsulates the tension between a thought that is non-arbitrary (reasoned) and yet uncertain (hypothesized) or as Harel and Sowder (1998) put it, "[a] conjecture is an observation made by a person who has doubts about its truth" (p. 241). Cañadas and Castro (2007) describe a seven-stage framework describing the inductive and deductive reasoning processes surrounding the act of making conjectures (Table 1). These stages provide nuance when examining the boundary between inductive and deductive reasoning.

Table 1: Framework for Inductive and Deductive Reasoning Processes

Stage	Description
Observation of particular cases	Experiences with particular cases of the problem posed
Organization of particular cases	Use strategies to systematize and facilitate the work with particular cases
Search and prediction of patterns	This pattern is not general, but based on specific observed cases to generate new ideas about possible cases
Conjecture formulation	Making a statement about all possible cases based on particular ones, but with an element of doubt (Reid, 2002)
Conjecture validation	Attempt to validate conjectures for new cases, but not in general.
Conjecture generalization	Hypothesizing that the conjecture is true beyond observed cases
General conjecture justification	Giving reasons that explain the conjecture with the intention of convincing another person that the generalization is justified.

Methodology

We asked seventeen PSMTs (working in small groups within a class period) to consider the question, *What conditions have to be satisfied for the perpendicular bisectors of the sides a quadrilateral to meet at a point?* We collected eight screencasts ("sessions") of partners working with DGS, which, along with transcriptions, makes up the corpus of our data. These sessions are typically 12–15 minutes long. For each session, we prepare a detailed narrative (Clandinin & Connelly, 2004) documenting *episodes of conjecturing* within the session. An episode of conjecturing is defined as a period of time during which there is sustained focus on one mathematical idea, even if that period does not include a *conjecture formulation* event. Breaks between episodes can be marked by a shift in focus or rejection of an idea/stated conjecture. Once we have established episodes, researchers began writing a narrative including descriptions of conjecturing behavior (CB) within. These drafts are reviewed and revised until consensus is

reached on the team. Final narratives are complex and include a transcript of the conversation, descriptions of visible, on-screen actions within the DGS environment, and identified CB linked to the framework above (Table 1).

The Case of Elijah and Grant

While a full analysis of all eight sessions is under way, the case of Elijah and Grant is worthy of intermediate attention because it contains five distinct episodes and opportunities to observe CB not included in the original framework. These episodes and the observed stages are summarized in Table 2. Stages in bold represent newly described CB.

Table 2: Observed Stages of Inductive Reasoning

Episode	Stages of Inductive and Deductive Reasoning Processes
Episode 1: Dragging Point D 1:40–3:49 minutes	Observation of particular cases (n = 6)
Episode 2: Visualizing and Exploring Angle Bisectors 4:12–5:55 minutes	Observation of particular cases (n = 2) Conjecture formulation *Attempted conjecture validation*
Episode 3: Perpendicular Bisectors/Side Length 6:00–7:19 minutes	Observation of particular cases (n = 2) Conjecture Formulation *Conjecture rejection*
Episode 4: Perpendicular Bisectors and Angle Measure 7:19–11:08 minutes	Observation of Particular Cases (n = 2) Search and Prediction of Patterns Observation of Particular Cases (n = 1) Conjecture Formulation Observation of Particular Cases Search and Prediction of Patterns Conjecture Validation Conjecture Generalization *Attempted conjecture justification*
Episode 5: Unfixing A,B, and C 11:13–13:30 minutes	Observation of particular cases (n = 4) Conjecture generalization

As Elijah and Grant worked through the task, the DGS environment supported multiple opportunities to observe particular cases and formulate conjectures. Further, the pair moved through five of the established stages; some stages multiple times. (For this paper, we will focus on Episode 4.) In this episode, the pair construct the perpendicular bisectors of all four sides and measure the four angles in the quadrilateral. They observe two cases and begin their search for patterns with two observations. First, the pair recalls that point C is fixed and angle C is a constant size (88.6 degrees). Second, there is a moment when Grant questions whether the intersection has to be "at the middle" of the quadrilateral. In this moment, there is a tacit acknowledgement that the intersection point was inside of the quadrilateral in both observed cases and Grant's question suggests that he isn't sure this would always hold true. He sees evidence of a pattern and questions whether it will hold up with additional examples. As they

identify one more example (see Figure 1), Grant begins to formulate a conjecture, with help from Elijah, which culminates with a confident generalization of the conjecture by Grant. The remaining time in the episode is spent trying to find technological solutions to pin the intersection point so that they can move D more confidently in the environment. Ultimately, they are unsuccessful, but remain confident in the statement of their conjecture.

Grant:	So maybe this one always has to be 91 [Angle D]… potentially because these were always 90. I think in… in at least our case. Yeah, I think it kind of always was around 91.
Elijah:	For it to be around 91 for it to be intersecting. [Drags point D in such a way to maintain the point of intersection and observe how angle D behaves.]
Grant:	[Confidently] Yeah. For it to intersect, it's got to be around 91 degrees.

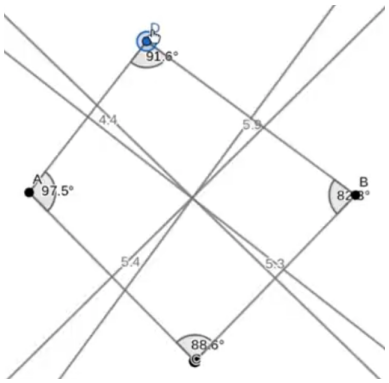

Figure 1: Transcript and Geometric Example from Episode 4

Findings and Implications

The methodological approach used in this study proved essential to the integrity of our findings, and this carries meaningful implications for researchers studying conjecture-making in technology-mediated environments. DGS, combined with Screencasting, enabled us to utilize a think-aloud protocol, linking conjecture to observed cases without researcher intervention or direct observation. The resulting data is an authentic representation of how students create, observe and interact with existing cases to formulate, generalize, and even reject conjectures. Even further, the process captures essential non-linear reasoning typically lost in final mathematical products.

While Cañadas and Castro's (2007) framework provides a rich description of the reasoning processes surrounding conjecture-making, our findings suggest that it may benefit from expansion to account for the full range of student experiences, particularly those involving invalid conjectures. In our data, we observed three stages not represented in the existing framework: *Attempted conjecture validation*, *Conjecture rejection*, and *Attempted conjecture justification* (see Table 2). These stages reveal that students frequently engaged in productive mathematical reasoning even when their conjectures were not valid. The current framework implicitly traces a successful path towards generalization and justification, but student reasoning is rarely so linear. When a student attempts to form or validate a conjecture and instead discovers a counterexample, this act of rejection is not a failure to progress through the stages. Instead, we have captured a meaningful reasoning event that may cycle back to earlier stages, shift in focus, or generate entirely new conjectures. By omitting these experiences, the framework does not illustrate a significant portion of students' mathematical activity. Future work might consider the iterative nature of inductive and deductive reasoning in authentic mathematical practice.

Detracking promotes equity but creates wide achievement ranges, prompting outside-the-school-day (OSD) math interventions. This qualitative case study examines OSD implementation in an urban Canadian school board using participant interviews. Wave 1 findings reveal four themes: recruitment/accessibility challenges, structural constraints, enabling factors, and professional learning needs. While small-group peer learning benefits students, implementation faces barriers like high ratios, limited training, and unclear communication. Resource limitations constrain impact despite creative adaptations

Keywords: Detracking, Instructional Practices, Equity in Education, Learning Trajectories

Introduction and Purpose

This study examines the implementation and effectiveness of the Outside the School Day (OSD) program for Grades 7–10 students at risk of not meeting provincial math expectations. Detracking aims to extend opportunities to all students (Mehan, 2015), but the broader range of abilities in these classrooms presents complex challenges (Parekh et al., 2021), revealing disparities in student readiness and hindering engagement and progress for students lacking foundational knowledge (Ree et al., 2023).

OSD programs aim to strengthen numeracy foundations, enabling students to better access and succeed in their math courses (Alegre et al., 2019). This study explores how these programs are implemented to meet student needs and support equitable outcomes. How do educators at one school site implement and adapt an OSD program to address math learning gaps in a detracked context? What implementation factors do educators identify as facilitating or constraining the OSD program's effectiveness?

This study is part of a broader Grade 9 mathematics study in a large urban district involving approximately 40 schools and 60 teachers. That study revealed widespread student learning gaps, prompting closer examination of OSD implementation through semi-structured interviews with a teacher, principal, and district learning coach.

Literature Review

Research demonstrates that well-designed OSD programs can significantly improve math achievement for struggling students. Key features associated with positive outcomes include small student-to-teacher ratios, frequent sessions, curriculum alignment with in-school instruction, and well-prepared teachers who build strong student connections (Nickow et al., 2023; Gallagher et al., 2022; White et al., 2023; Alegre et al., 2019). Early intervention and summer intensive sessions yield particularly strong results (Knopf et al., 2015; Chappell et al., 2015), suggesting OSD programs can serve as strategic equity tools in detracked settings where classroom heterogeneity complicates targeted instruction (Gortazar et al., 2023).

However, research remains heavily weighted toward whether programs work while providing limited insight into how they are implemented in practice (Munter et al., 2015). Notably, the existing OSD literature has largely developed in tracked or mixed contexts where students receiving supplementary support have already been identified. OSDs developed in response to detracking present a distinct challenge: they must address the full range of foundational gaps that detracking surfaces, serve a larger and more heterogeneous population, and align with grade-level curriculum all students are now expected to access. Whether design features associated with effective OSDs in the existing literature translate to this detracked context remains an open question this study addresses.

Theoretical Framework

Program Implementation Theory (Boylan, 2025; Munter et al., 2015) provides a framework for examining how design, delivery, and contextual adaptations shape implementation processes. Key constructs include implementation fidelity (adherence to program design), local adaptation (modifications to fit context), and the tension between these competing demands. This tension is particularly salient in detracked settings, where OSDs must simultaneously address heterogeneous learning gaps while remaining aligned with grade-level curriculum — a dual demand that programs designed in tracked contexts were not built to meet.

Methods

This ongoing study employs a qualitative case study design with data collection across two time points during the 2025-26 school year, exploring the perspectives of a learning coach, principal, and teacher at the implementation site. Each participant is being interviewed twice: once shortly after program commencement (completed Fall 2025) and again at year-end (scheduled June 2026), for a total of six semi-structured interviews of approximately 45-60 minutes each. These roles represent different implementation levels: school-based delivery (teacher), school leadership (principal), and system-level support (learning coach). Complementary document analysis will capture formal structures guiding implementation. Ethics approval was obtained from the University of Toronto and the participating school board. Trustworthiness is being enhanced through data triangulation, member checking, and maintenance of an audit trail.

Data Analysis

Interviews were transcribed and imported into Nvivo 12 for analysis. Following an inductive thematic approach, data were open-coded to identify emergent themes related to program implementation, coaching practices, and perceived effectiveness. Consistent with Program Implementation Theory, the coding framework attended to three constructs: implementation fidelity, local adaptation, and fidelity-adaptation tension, applied deductively alongside inductive open coding. Trustworthiness was enhanced through triangulation of interview and document data and member checking with participants.

Results

Analysis of Wave 1 interviews revealed four major themes: (1) recruitment and accessibility challenges, (2) structural constraints, (3) enabling factors, and (4) professional learning and resource needs.

Recruitment and Accessibility Challenges

Getting students to participate emerged as a significant barrier. The teacher described intensive outreach: "I had to make many phone calls to parents to entice them and to promote the program. With persistence, more students joined" (Interview, October 14, 2025). The learning coach noted system-level difficulties expanding beyond current sites. Accessibility barriers further limited participation, with the learning coach emphasizing the need for virtual and evening options for students with transportation, caregiving, or work responsibilities. That those with the greatest needs face the greatest barriers suggests structural features are undermining fidelity to the program's equity goals.

Structural Constraints

While OSD classes were smaller than regular instruction, ratios remained high for intensive remedial work, with "a minimum of 15" (Learning Coach, September 29, 2025), limiting individualized attention. Resource limitations constrain impact, and program purpose confusion further complicated implementation: "The parameters are to fill numeracy gaps…this is not a homework club" (September 29, 2025). These findings suggest structural fidelity (appropriate ratios, resources, and shared understanding) is a prerequisite for the instructional fidelity the program requires.

Enabling Factors

Despite constraints, participants identified several factors supporting student learning. The teacher reported gains through small-group peer learning and noted that students not attending day school regularly were attending the OSD program. A local bakery provided breakfast to support attendance, and a community volunteer extended instructional capacity. These grassroots adaptations illustrate how school-level actors supplement formal structures when full fidelity is not feasible, a dynamic central to the fidelity-adaptation tension.

Professional Learning and Equity Considerations

Teacher preparation emerged as a critical fidelity risk, with the learning coach recommending math Additional Qualifications to strengthen instructional understanding (Interview, September 29, 2025). Equity considerations shaped enrollment, with priority given to students with the greatest need. However, the absence of systematic data tracking limits the program's ability to demonstrate impact and justify future funding. Across participants, a tension emerged between program potential and implementation reality.

Conclusion

Preliminary findings show that while OSD programs show promise, implementation faces significant barriers echoing concerns in the broader literature. High student-to-teacher ratios undermine the individualized attention Nickow et al. (2023) and Alegre et al. (2019) identify as central to effective supplementary math programs. Teacher preparation gaps align with Munter et al.'s (2015) observation that implementation research underestimates the instructional capacity interventions require. Community-level adaptations reflect what Boylan (2025) describes as school-level actors compensating for design shortfalls. These challenges are inseparable from the detracked context: by expanding the population requiring support while removing existing identification structures, detracking places demands on OSD design the existing literature has not yet addressed. Wave 2 data will examine whether these barriers persist as the program matures. While generalizability is limited by the single-site design, this study contributes critical insights into how supplementary interventions function within detracked systems, pointing toward design principles the field has yet to develop.

Funds of knowledge provide an avenue for bridging the gap between students' lived experiences and school mathematics. In this study, we examined research trends on funds of knowledge in mathematics education, focusing on empirical studies. A total of 63 articles were identified through ERIC and Google Scholar, screened using established criteria, and analyzed thematically. Findings indicate that these studies primarily center on task and curriculum design, community and family engagement, and teacher capacity building. Studies involving classroom instruction were mainly conducted at the elementary and middle school levels and commonly used qualitative, participatory, and community-based approaches.

Keywords: Culture and Asset-Based Pedagogies; Equity, Inclusion, and Diversity

The mathematics classroom in the United States is increasingly diverse with the growth of K–12 student populations (US Government Accountability Office, 2022). However, instruction remains standardized, creating a disconnect between school mathematics and students' lived experiences and contributing to persistent achievement gaps (Goethe & Colina, 2018). When teachers do not understand students' contexts, they may struggle to address diversity, affecting student performance (Clement et al., 2020; Insorio, 2024). The funds of knowledge framework (Moll et al., 1992) addresses this challenge by centering home and community (Moll et al., 1992; Velez-Ibanez, 1998; Moje et al., 2004). In mathematics education, it supports engagement by linking school mathematics to these resources, including everyday practices such as budgeting and cooking (Civil, 2007; Turner & Drake, 2016; Hurtado, 2018; Napoli & Purpura, 2018). Scholars note that such connections can strengthen participation and potentially improve achievement through more meaningful home–school integration.

Although widely studied in general education, with Moll et al. (1992) highly cited (Denton & Borrego, 2021) and contributions such as Gonzalez (2005), mathematics education lacks a focused synthesis. Existing scoping reviews cover education and STEM broadly (Denton & Borrego, 2021; Llopart & Esteban-Guitart, 2018) but not mathematics. Given its relevance to learning (Hurtado, 2018; Napoli & Purpura, 2018), this study conducts a scoping review of empirical studies to examine how funds of knowledge is applied and identify research gaps. It is guided by the question: What are the characteristics of studies that have applied the funds of knowledge framework in mathematics education, including those situated specifically in classroom instruction?

Funds of Knowledge

The concept of funds of knowledge emerged from work in multilingual, transnational, and borderland communities in the United States. Rodriguez (2013) noted that it was proposed to challenge deficit thinking, racial discrimination, and unequal power relations in education by

recognizing the strengths of multilingual communities. Velez-Ibanez (1988) defined funds of knowledge as the skills and information households use for survival, while Moll et al. (1992) described it as "historically accumulated and culturally developed bodies of knowledge and skills" (p. 134). These resources are embedded in households and communities. Gonzalez (2005) further conceptualized funds of knowledge as cultural capital developed over time, including labor skills, family interactions, and shared experiences from formal and informal activities.

Methods

This study adopts the scoping review framework proposed by Arksey and O'Malley (2005). Scoping reviews are used to map literature on emerging research topics (Mak & Thomas, 2022) and to examine the range and nature of research activities within a field (Arksey & O'Malley, 2005). In this study, the framework was used to investigate the characteristics of funds of knowledge research in mathematics education. Arksey and O'Malley (2005) outlined five stages of the process: (a) identifying the research questions, (b) identifying relevant studies, (c) selecting studies, (d) charting the data, and (e) collating, summarizing, and reporting the results.

Identification and Selection of Studies

Studies were *included* if they were (a) empirical, (b) grounded in the funds of knowledge framework, (c) focused on mathematics, (d) published between 2015–2025, and (e) published in peer-reviewed journals or conference proceedings, to capture recent developments in mathematics education research. Studies were *searched* through ERIC and Google Scholar using the keywords "funds of knowledge" and "mathematics," and the first 20 results from each database were *screened* by title and abstract due to practical constraints in manual screening. While this approach may not capture the full scope of relevant literature, it will be expanded in later phases of the study.

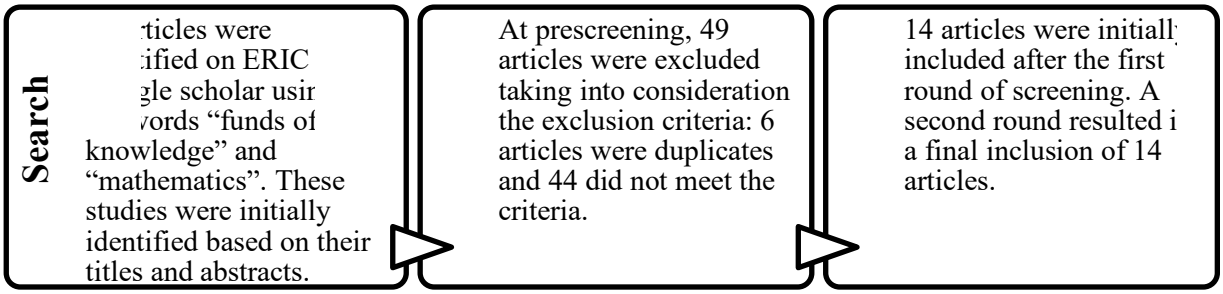

Figure 1: Article Search and Selection Procedures

Data Charting and Analysis

Consistent with Arksey and O'Malley's (2005) scoping review framework, each of the 14 included articles was read in full and open-coded by the research team. Codes captured multiple dimensions, including study purpose, theoretical framing, participants, methodological approach, mathematical content or tasks, and key findings. These codes were then compared and iteratively grouped into broader themes aligned with the exploratory aims of the scoping review.

Results

Fourteen studies met the inclusion criteria for the scoping review. Thirteen were journal articles and one was a conference proceeding, and all were analyzed in relation to the research questions.

Characteristics of Studies Applying Funds of Knowledge in Mathematics Education

To address the research question, we examined studies applying the funds of knowledge framework in mathematics education. The purpose, theoretical framing, methods, analysis, and findings of the 14 studies were reviewed, yielding three themes: (a) mathematics tasks and curriculum design, (b) family and community engagement, and (c) teacher capacity building.

Mathematics tasks and curriculum design. One major characteristic of studies applying funds of knowledge in mathematics education focused on mathematics tasks and curriculum design, with seven studies aligned to this theme. These studies connect school mathematics to students' lived experiences and cultural backgrounds by embedding learning in familiar contexts rather than treating mathematics as culturally neutral or abstract. Ma (2016) contrasted traditional instruction with "disruptions" that bridge home and school knowledge by taking geometry outdoors, where students used everyday resources such as language and body movement to explore geometric shapes. Similarly, Hunter and Sawatzki (2019) developed a contextualized problem-solving task for Pacific Islander students involving sharing the cost of a family meal, integrating division with cultural practices of fairness and decision-making. Turner and Drake (2016) emphasize curriculum flexibility to support multiple strategies drawing on students' out-of-school experiences. Overall, these designs make mathematics more inclusive and highlight its relevance in real-world contexts.

Family and community engagement. Instead of viewing family and community as outsiders to school mathematics, some studies position family, parents, and community members as partners in the learning process. Five studies highlight this role, strengthening home–school connections by linking home activities to classroom mathematics. Suh and Calabrese (2025) illustrate this by having students bring family photographs and artifacts as starting points for mathematical questions and discussion, an example of mathematizing everyday family life. Gutiérrez et al. (2024) similarly used workshops with Latina mothers to engage community knowledge, grounding tasks in caregivers' funds of knowledge such as crafts, cooking, and budgeting. These workshops showed how family practices can be explicitly connected to mathematical practices (Suh & Calabrese, 2025).

Teacher capacity building. Another important theme in the literature is capacity building for mathematics teachers. Many teachers struggle to integrate family, cultural, or community funds of knowledge into instruction. Turner and Drake (2016) found that incorporating students' cultural and community experiences supports diverse learners' participation and helps teachers better address classroom diversity. Kalinec-Craig and Zavala (2019) further support teacher capacity through the community mathematics exploration (CME), which uses videos and texts reflecting students' cultural practices to help teachers design lessons grounded in learners' community experiences.

Characteristics of Studies Applying Funds of Knowledge to Mathematics Instruction

The broader thematic patterns indicate that funds of knowledge research in mathematics education is closely aligned with teaching and instruction, particularly through mathematical task and curriculum design. Results from research question one suggest these studies primarily focus on task design and curriculum and are strongly connected to mathematics instruction. Given the potential of funds of knowledge to improve instruction and performance (Hurtado, 2018; Napoli & Purpura, 2018), we further examined this context by analyzing a subset of 10 classroom instruction studies, organized into three categories based on methodological approach, participants, and mathematical examples used.

Methodological approaches. Seven studies used qualitative, community-based designs, including photovoice (Hunter, 2022), home math interviews (Williams et al., 2020), and community mathematics walks (Kalinec-Craig & Zavala, 2019; Ma, 2016). Six studies used participatory approaches that positioned families and students as active contributors, and five incorporated classroom artifacts and student-centered tasks grounded in authentic, real-world contexts. These modeling activities drew on learners' mathematical knowledge and community norms in decision-making (Bennett et al., 2023; Gutiérrez et al., 2024). Most studies used qualitative methods, with only two employing mixed-methods designs (Suh & Calabrese, 2025), enabling examination of how students' funds of knowledge are contextualized in mathematics classrooms.

The participants. The funds of knowledge literature in mathematics education spans multiple populations, but most studies focus on elementary and middle school contexts. Four studies involved elementary learners (Bennett et al., 2023; Hunter, 2022; Suh & Calabrese, 2025; Williams et al., 2020), and four included middle school students (Hunter, 2022; Hunter & Sawatzki, 2019; Ma, 2016; Williams et al., 2020). Studies also examined preservice and in-service teachers (Hunter & Sawatzki, 2019; Kalinec-Craig & Zavala, 2019; Kelley, 2020; Suh & Calabrese, 2025; Gutiérrez et al., 2024), while some involved parents (Williams et al., 2020; Gutiérrez et al., 2024). Overall, the concentration of studies at the elementary and middle school levels highlights the importance of community and family experiences in supporting mathematics learning during these years.

Mathematical examples or activities and their content domains. The studies incorporated mathematical tasks grounded in learners' family and community practices, including financial decision-making (e.g., budgeting and shopping), food preparation, and fair-share or proportional reasoning (Bennett et al., 2023; Hunter & Sawatzki, 2019; Ma, 2016). These tasks positioned students' cultural and household experiences as authentic contexts for mathematical learning. Numbers and operations were most common, appearing in nine of ten studies, followed by ratio and proportional reasoning (seven), measurement (six), and data modeling (five). Only one study addressed geometry explicitly (Ma, 2016), though visual representations appeared in studies using artifacts and photovoice methods (Hunter, 2022; Kalinec-Craig & Zavala, 2019). No study focused explicitly on algebra, despite implicit algebraic reasoning.

Discussion and Implication

The findings of this review indicate that mathematics education studies using funds of knowledge primarily focus on mathematical task and curriculum design, community and family engagement, and teacher capacity building. This aligns with Llopart and Esteban-Guitart (2018), who identified curriculum contextualization and family–school relationships as key applications of funds of knowledge in general education, suggesting mathematics education has largely adapted rather than developed discipline-specific approaches. In contrast to Denton and Borrego (2021), teacher capacity building is more prominent in mathematics education.

Regarding classroom instruction, the dominance of qualitative, participatory, and community-based methods mirrors broader research but limits evidence for achievement claims (Hurtado, 2018; Napoli & Purpura, 2018). Mixed methods studies would strengthen future work. The concentration at elementary and middle levels, with limited algebra-focused research, highlights a gap that may hinder students' transition to abstract reasoning, making expansion into secondary contexts important. Although teacher capacity building is common, it often relies on isolated interventions such as community mathematics exploration models (Kalinec-Craig & Zavala, 2019; Williams et al., 2020), indicating a need for more scalable approaches.

MAPPING COMPUTATIONAL THINKING IN MODULAR ARITHMETIC PROBLEM-SOLVING: EPISTEMIC NETWORK ANALYSIS

Marta T. Magiera
Marquette University
marta.magiera@marquette.edu

Using Epistemic Network Analysis, this research examined how problem-solvers (prospective elementary school teachers) integrate computational thinking (CT) practices in their solutions to modular arithmetic tasks. Analysis of written solutions and accompanying explanations (n = 22) revealed three statistically distinct profiles of CT engagement: Synergistic and Abstract (associated with optimization-oriented strategies), Integrated and Procedural (associated with verification-oriented strategies), and Narrow and Fragmented (associated with trial-and-error oriented strategies). Results demonstrate clear links between solution sophistication and the patterns of interaction among CT practices. The study offers a new framework for scaffolding CT in mathematical problem-solving, suggesting that moving students towards the mathematical efficiency of solutions requires fostering synergies between abstraction and pattern recognition.

Keywords: Computational Thinking, Problem-Solving, Cognition, Undergraduate Education

Introduction

Computational Thinking (CT) constitutes one of the fundamental problem-solving competencies for participating in today's society (Li et al., 2020; Shute et al., 2017; Tariq et al., 2025). Wing (2006) initially introduced CT as a problem-solving approach that draws on practices from computer science. Since then, CT has been recognized as encompassing a broad range of skills and ways of thinking shared across STEM disciplines and applied to everyday problem-solving, rather than a computer science-specific competency (Kallia et al., 2021; Listjaji & Molnar, 2025; Weintrop et al., 2016).

In recent years, mathematics education researchers have begun to generate an understanding of the relationship between CT and mathematical problem-solving processes. Some researchers examined CT practices that problem-solvers frequently draw on during mathematical problem-solving (Cui et al., 2023; Hong et al., 2021; Ng & Cui, 2021). Others (Labusch et al., 2019; Lehmann, 2024, 2025; Wu et al., 2024; Ye et al., 2024) focused on CT practices that problem-solvers activate during different phases of problem-solving, such as problem understanding, planning, carrying out the plan, looking back, or in conjunction with different problem-solving heuristics (e.g., drawing a diagram, working backward, examining special cases).

While past research provides insights into CT practices in problem-solving contexts, it falls short of explaining how problem-solvers connect the CT practices they draw on as they generate problem solutions. To date, limited research has examined how different CT competencies, such as problem decomposition, abstraction, algorithmic thinking, pattern recognition, and debugging, interact and support one another in the problem-solving process. Ye and colleagues (2024) argued that a robust understanding of the relationship between CT and mathematical thinking in problem-solving requires an understanding of possible links between CT and different solution strategies. This study responds to this call by utilizing Epistemic Network Analysis (ENA) to explore patterns of problem-solvers' CT engagement in the problem-solving context. Drawing on written task solutions, the following question was addressed: *What does the analysis of the*

strategies problem-solvers use to solve contextual modular arithmetic tasks reveal about their engagement in CT?

Theoretical and Analytical Frameworks

Epistemic Frame Theory

Epistemic Frame Theory (Shaffer, 2006) builds on the concept of a *frame*, an organizational principle introduced by Goffman (1974) that reflects how individuals filter information and organize their understanding of the given situation to guide their future actions. Shaffer expanded the concept of the epistemic frame using it as a window into an individual's thinking in domain-specific situations. He subsequently developed Epistemic Network Analysis (ENA), an analytical tool for studying thinking processes. ENA shifts the focus of analyzing one's cognitive engagement from examining isolated pieces of information about one's thinking to exploring the structure of connections among identifiable cognitive actions. It allows the identification and quantification of cognitive processes and the visualization of their relationships (Shaffer, 2017; Shaffer et al., 2016). The method has been widely used in educational research to explore how knowledge is constructed or shared (e.g., Bressler et al., 2019; D'Angelo et al., 2020; Orill & Brown, 2023; Su et al., 2023; Ye & Zhou, 2022).

ENA models connections between the identified data features (codes) by representing their co-occurrence, both visually and statistically. As such, ENA reveals the underlying structure of cognitive engagement within a dataset. This modeling approach is particularly useful for studying engagement in CT because it captures the dynamic integration of multiple CT practices as they unfold during the problem-solving activity.

Computational Thinking

The analytical framework for this research draws on existing CT literature to operationalize CT as an interdependent set of practices (Grover & Pea, 2012; Shute et al., 2017; Weintrop et al., 2016). These include abstraction and problem reformulation, problem decomposition, algorithmic thinking (algorithm design), pattern recognition, and debugging. These aspects of CT are central to mathematical problem-solving, encompassing processes such as generating procedures, recognizing patterns, evaluating strategies, and constructing generalizable rules (Lehmann, 2025; Weintrop et al., 2016). Table 1 defines the CT dimensions examined in this study.

Table 1: Dimensions of CT

CT Dimension	Evidence in problem-solving
1. Abstraction/Problem Reformulation (ABS)	Identifies essential conditions and converts problem information into a mathematical structure.
2. Decomposition (DEC)	Breaks the problem into smaller steps (subproblems).
3. Algorithmic Thinking (ALG)	Develops a repeatable, logical strategy or incremental solution plan (rule, sequence of steps).
4. Pattern Recognition (PAT)	Identifies helpful regularities.
5. Debugging (DEB)	Checks the consistency of the solution, corrects, and revises as needed.

Method

Study Context and Participants

The participants were 22 undergraduate students (all non-STEM majors) enrolled in the mathematics *Problem Solving and Reasoning for Teachers* course at a Midwestern University. They were all in their first or second year at the University and volunteered their participation. The course was structured to provide the students with problem-solving experiences across a broad range of problems and problem-solving strategies.

Modular Arithmetic Problems

Contextual modular arithmetic problems provide a revealing context for the study of CT because they uniquely prompt engagement with CT practices by requiring decomposition of the problem context, abstraction, algorithm development, monitoring one's reasoning, identification of errors, and iterative refinement of strategies (Cripa et al., 2025). Solutions to contextual modular arithmetic problems demonstrate not only problem-solvers' engagement with different CT practices but also their understanding of mathematical structure. Furthermore, these types of problems can also expose conceptual gaps when the algorithms developed to solve them break down. Figure 1 shows the problem used in this study.

> **Corporation Meeting**. Dayna was in charge of a large corporation meeting. She wanted everyone to work in groups, and she really wanted all the groups to be the same size. She started out by organizing everyone into groups of 6, but one person was left out and didn't have a group. So she started over again and organized everyone into groups of 7, but again, there was one person left out. So she tried again, this time organizing everyone into groups of 8, and this time, there were five people left out. So, finally, she organized everyone into groups of 5, and nobody was left out. There were less than 100 people at the meeting. How many people were there?

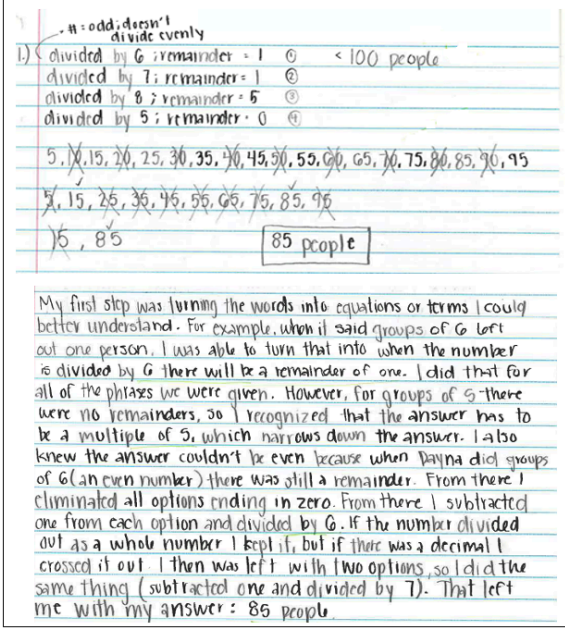

Figure 1: Modular Arithmetic Task

Data and Data Analysis

The data consisted of written responses (problem solutions and accompanying explanations, $n = 22$) to the task presented in Figure 1. The first stage of data analysis was grounded in qualitative content analysis and analytical inductive methods (Miles et al., 2018). Using open coding, each response was annotated to delineate the overall solution strategy. Each solution was also coded for the correctness of the answer. The author and the research assistant discussed their independent observations until they reached 100% agreement on the overall solution strategy profiles identified across the data. These solution profiles were then labeled as (a) *optimization-oriented strategies,* (b) *verification-oriented strategies,* and (c) *exploration-oriented strategies*. Each solution profile is later described in the results section.

The second stage of the analysis focused on creating and validating ENA models to illustrate and describe the patterns of interactions among the CT practices documented in each response. This stage involved utilizing the moving-stanza-window method (Shaffer et al., 2016) and parsing each response into segments (stanzas) that reflected distinct problem-solving moves. Each segment corresponded to a single step in the solution process or a distinct mathematical claim. Using a priori defined codes consistent with the analytical framework (Table 1), each segment was coded for evidence of CT practices. Figure 2 provides a sample response and coding to illustrate this stage of the analysis. Across the entire data corpus, 127 stanzas were

delineated and coded. Finally, the ENA web tool (Marquart et al., 2018) was used to create and compare the models of CT engagement for problem-solvers with different solution profiles. The unit of analysis for this step was the solution profile, that is, the group of participants with the same strategy profile. In group model development, the ENA conversation was defined as all lines of code associated with each participant within the given solution profile (optimization-oriented, verification-oriented, or exploration-oriented). Models were developed by quantifying code co-occurrence within conversations, producing weighted co-occurrence networks and associated visualizations for each unit of analysis in the data. CT network difference graphs were constructed (by calculating differences in the weights of corresponding connections across solution profile groups) to provide a visual comparison of CT engagement for each solution profile group. The Mann-Whitney *U* test was used to examine differences among the CT networks for optimization-oriented, verification-oriented, and exploration-oriented groups.

Response Segments	Coding	Justification
1. My first step was turning the words into equations I could better understand. For example, when it said groups of 6 left one person, I was able to turn it into when the number is divided by 6, there will be a reminder of 1...."	ABS	**Abstraction:** Translates contextual information to a mathematical description using mathematical symbols
2. However, for groups of 5 there were no reminders, so I recognized that the answer has to be a multiple of 5.	ABS DEC	**Abstraction:** Identifies a global property that describes the numerical result (number has to end in 0 or 5) **Decomposition:** Narrows the problem space to a subset of multiples of 5.
3. I also knew that the answer couldn't be even because, when Dana did groups of 6, there was still a reminder.	ABS PAT DEC	**Abstraction:** Further considers the global property of the answer (answer can't end in zero) **Pattern:** Recognizes that the answer will end in 5 **Decomposing:** Eliminates unnecessary entries and further reduces the problem space to odd multiples of 5
4. From there, I subtracted 1 from each option and divided by 6...	ALG DEB	**Algorithm:** Identifies and applies a specific iterative sequence of steps (subtract 1, divide by 6) **Debugging:** Uses a whole number vs. a decimal as a self-check. Checks the final two results against the remaining conditions.

Figure 2: Sample Response and Coding (Optimization-Oriented Strategy)

Results

Solution Profiles

The analysis revealed three distinctive solution strategy profiles across the responses: (a) *optimization-oriented*, (b) *verification-oriented*, and (c) *exploration-oriented*.

Problem-solvers whose solutions were categorized as *optimization-oriented* ($n = 8$) developed the most computationally efficient strategies. This group of problem-solvers drastically reduced the problem space early in the process by strategically reasoning about the properties of potential solution candidates and generating new rules. By doing so, they rapidly advanced towards the final answer. All solutions within this group were correct.

Problem-solvers whose strategies were categorized as *verification-oriented* ($n = 8$) utilized a highly organized procedural approach. They documented and validated the problem constraints, revisited assumptions, and recalculated results to ensure accuracy of their work at every step. They consistently checked intermediate results to maintain internal consistency and ensure

alignment of their work with the problem constraints. Also in this group, all solutions were correct.

Exploration-oriented strategies (n = 6) were characterized by brute-force or trial-and-error approaches. Problem-solvers in this group documented their iterative reasoning but often lacked a cohesive framework to guide their work. For example, some participants examined numbers against problem constraints (e.g., tested numbers from a list of 1–99). Other participants generated separate lists of multiples of 6, 7, 8, and 5 and examined them independently, checking each constraint without making connections across their lists. Their solutions included evidence of strategy adjustments and changes in the representations used only after discovering an error or a dead end in their arithmetic calculations. Within this group of responses, three included the correct answer, and three did not.

Engagement in CT Practices

The ENA analysis revealed statistically significant differences in CT engagement among problem-solvers with different solution profiles. As shown in Figure 3, these differences are indicated by the non-overlapping 95% confidence intervals surrounding the centroids, which represent normalized mean CT networks for problem-solvers in each solution profile group. The horizontal dimension of ENA space (SVD1, 71.9% variance) explains the shift in co-occurrence of CT practices from optimization-oriented to exploration-oriented solution strategies. The vertical dimension (SVD2, 9.3% variance) captures co-occurrences of CT practices that distinguish the verification-oriented group from both the optimization and exploration-oriented groups.

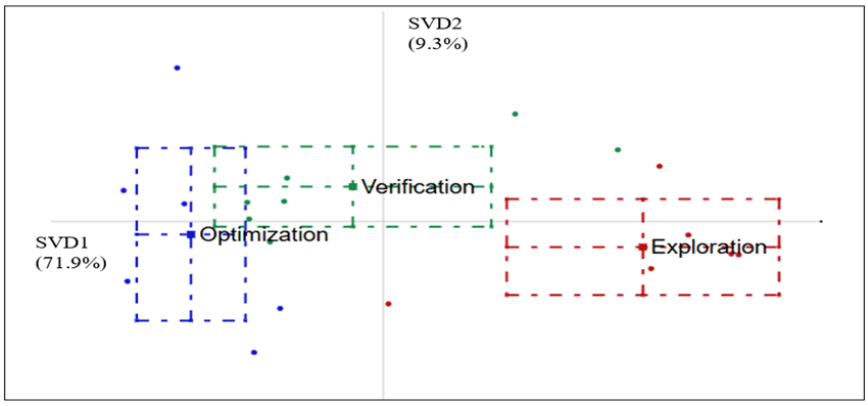

Figure 3: Network Centroid Plots of CT Engagement for Optimization (Blue), Verification (Green), and Exploration (Red) Solution Profile Groups

The patterns of CT engagement among problem-solvers with optimization-, verification-, and exploration-oriented solution strategies are further illustrated in Figure 4 through their respective CT engagement networks. The nodes of each network graph correspond to the analytical codes (Table 1), and the edges reflect the relative frequency of co-occurrence (connections) between the codes within each solution-profile group. The strongest co-occurrences among the five CT practices are visualized by edge thickness, with the thickest lines representing the most frequent connections.

The ENA revealed that the *optimization-oriented* group (Figure 4a) used a highly connected network of CT practices, dominated by abstraction, pattern recognition, decomposition, and debugging. This group of problem-solvers likely drew on abstraction to discover new patterns

that helped them "simplify" the solution process. By leveraging synergies among the CT practices in their network, this group of problem-solvers bypassed the frequent reliance on algorithmic steps, enabling them to generate computationally efficient strategies.

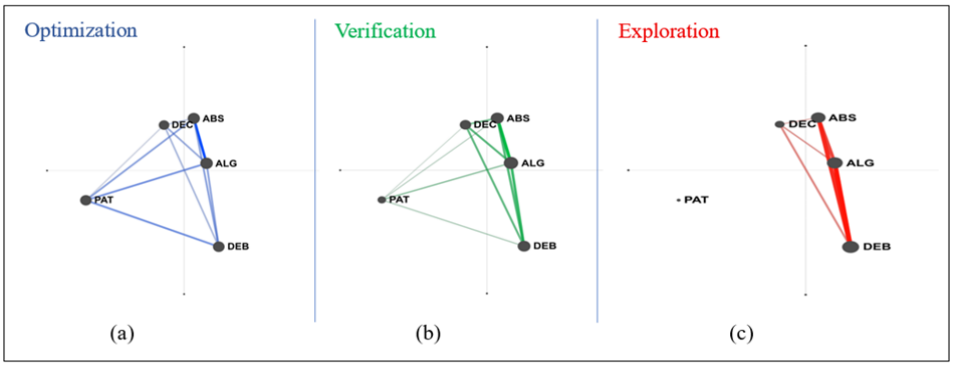

Figure 4: CT Networks for Each Solution Profile Group

The *verification-oriented* group (Figure 4b) also engaged in a range of highly integrated CT practices (abstraction, decomposition, algorithms, and debugging). Their network, however, was largely disconnected from pattern recognition, as evidenced by weaker links between pattern recognition and the remaining four practices. The weaker link between pattern recognition and abstraction in this group suggests that while they may have used abstraction to define problem constraints, they did not use it to discover any new rules within the problem. Consequently, their systematic solutions stemmed from careful implementation of procedures and a systematic focus on result validation.

Finally, the ENA revealed that the *exploration-oriented* group used a narrower and more fragmented set of CT practices (Figure 4c) that primarily included abstraction, algorithmic thinking, and debugging. The strongest co-occurrence within their network was between abstraction and algorithmic thinking, and between algorithmic thinking and debugging. As illustrated in Figure 4c, within this group, connections among decomposition and abstraction, algorithmic thinking, and debugging were weak, and their CT network was entirely disconnected from pattern recognition. The absence of pattern recognition and a limited focus on decomposition might have led to a trial-and-error or brute-force approach, given that this group was not associating any new rules with the problem space.

Group Comparisons of CT Engagement

Figure 5 includes an ENA-generated comparison networks that visualize differences in CT engagement between the optimization and verification and the optimization and exploration-oriented groups. The engagement in CT practices within the optimization group (Figure 5a) was dominated by abstraction, pattern recognition, decomposition, and debugging. The strong connection between abstraction and pattern recognition suggests that the problem-solvers in this group likely used abstraction to discover new patterns, which helped them 'simplify' the problem space rather than merely represent the problem mathematically. By leveraging synergies among the CT practices in their network, they bypassed the frequent reliance on algorithmic steps, as documented by the lower density edges to a node representing algorithmic thinking in Figure 4a and the absence of a connection to algorithmic thinking in Figure 5a. In contrast, the engagement in CT practices within the verification-oriented group was dominated by algorithmic thinking

and debugging (Figure 5a). The lack of a strong link between pattern recognition and abstraction in the verification group suggests that these problem-solvers may have relied on abstraction to define problem constraints but did not use it to discover any new rules within the problem. Consequently, they focused on systematic procedures and careful verification of results rather than finding logical shortcuts.

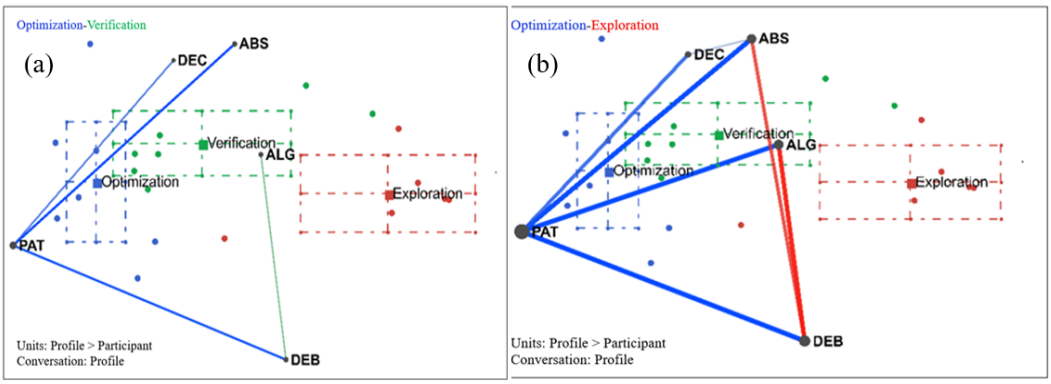

Figure 5: Comparison Graphs Illustrating Differences in the Co-Occurrence of CT Practices Between the (a) Optimization (Blue) and Verification (Green), and (b) Optimization (Blue) and Exploration-Oriented (Red) Groups

A comparison graph of engagement in CT practices between the optimization- and exploration-oriented groups (Figure 5b) shows that the exploration group showed no engagement in pattern recognition. As illustrated in Figure 4a, in the optimization-oriented group, pattern recognition served as a central hub, mediating connections to abstraction, decomposition, algorithmic thinking, and debugging. In contrast, the network illustrating CT engagement for problem-solvers in the exploration group (Figures 4c and 5b) was limited and clearly disconnected from pattern recognition. This structural network difference indicates that, unlike the optimization group, problem-solvers with the exploration-oriented strategies predominantly used abstraction to represent the problem constraints (mathematize the verbal description of the problem) rather than as a tool for generating ideas, deriving new rules and shortcuts, and gaining insights into the problem structure. The lack of engagement in pattern recognition likely explains this group's reliance on guess-and-check and brute-force approaches in the absence of the structural anchors needed to move beyond guessing-and-checking.

A visual comparison of engagement in CT practices between the verification and exploration groups is shown in Figure 6. Pattern recognition remained strongly connected to all other CT practices in the verification group (Figure 4b and Figure 6), but, as discussed earlier, the problem-solvers in the exploration-oriented group did not engage in this practice (Figure 4c and Figure 6).

The Mann-Whitney *U* test confirmed that the co-occurrence of CT practices differed significantly at the 0.05 level across all group comparisons. Significant differences were between the optimization-oriented (Mdn = –0.26, $n = 8$) and verification-oriented (Mdn = –0.12, $n = 8$) groups; $U = 5.00$, $p = 0.01$, $r = 0.82$. The same was true when comparing the co-occurrence of CT practices between the optimization-oriented and exploration-oriented (Mdn = 0.41, $n = 6$) groups; $U = 0.001$, $p < 0.01$, $r = 1.00$, and between the verification-oriented and exploration-oriented groups; $U = 2.00$, $p < 0.001$, $r = 0.90$. In each case, the effect size was large, indicating

substantial differences in CT engagement patterns among problem-solvers across these three solution profiles.

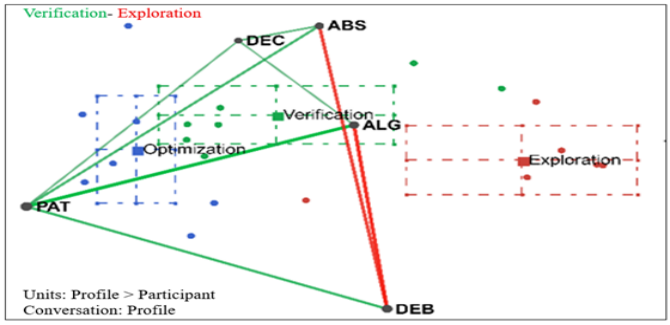

Figure 6: Comparison Graph Illustrating Differences in the Co-Occurrence of CT Practices Between the Verification-Oriented (Green) and Exploration-Oriented (Red) Groups

Conclusion

This study shifts the focus of past research from the examination of individual CT competencies that problem-solvers demonstrate to the examination of these competencies as interdependent networks, and offers insights into the potential trajectories of CT engagement in problem-solving contexts. This study also identifies the mechanisms that might support problem-solvers in increasing the efficiency of their strategies during complex problem-solving.

The results show that the optimization-oriented group's efficiency, specifically their ability to eliminate much of the computational labor, can be explained by a unique synergy among abstraction, pattern recognition, decomposition, and debugging. In their CT network, pattern recognition served as a central hub, providing cognitive shortcuts and structural insights into the problem, thereby supporting the computational efficiency of solutions. The verification-oriented group achieved accuracy through a highly connected synergy of algorithmic thinking and debugging, which served as the primary driver of their work. The exploration-oriented group's network of CT practices was narrower and lacked engagement in pattern recognition, likely leaving these problem-solvers without a robust framework for their work.

While limited to one type of problem and a small sample, the results point to a critical synergy between the strength and nature of connections across CT practices and the problem-solving strategies. Further research should use ENA to investigate whether the identified network profiles of CT engagement remain stable when problem-solvers work on tasks of varying complexity or in different mathematical domains. Future research should also apply ENA to real-time transcripts of problem-solving sessions (think-aloud protocols and observations) to further visualize how problem-solvers' engagement in CT evolves across different stages of the problem-solving process. Despite these limitations, the current study serves as a critical step towards understanding how problem-solvers' CT capacities are networked and provides a bridge to understanding CT integration in mathematics education.

BRIDGING WORDS AND GRAPHS: THIRD-GRADE STUDENTS' MATHEMATICAL REASONING WITHIN MULTIMODAL TEXTS

This study investigates how third-grade students interpret and integrate verbal and graphical information in a multimodal mathematical text. Grounded in theories of dual-coding, data display comprehension, and question-answer relationships, this research focuses on students' processes for answering questions using information from text, a pictograph, or both. Analyses of eye tracking data combine verbal protocols, fixation counts, dwell time, and visual pathways. Results show most students relied primarily on the pictograph and answered correctly when information was duplicated across modalities. However, students who depended solely on text were often incorrect even when adequate information was available. While most students successfully extracted data from the pictograph, few integrated information from the key, indicating limited information integration.

Keywords: Elementary School Education, Mathematical Representations, Eye Tracking, Multimodal Text

Objectives or Purposes of the Study

Multiple representations are an important part of mathematics learning, providing opportunities to apply skills to information in multiple embodiments. Lesh et al. (1987) highlighted verbal and pictorial representations alongside other mathematical representations embodying "critical features of mathematical constructs and actions, such as drawing diagrams and using words to show and explain the meaning of fractions, ratios, or the operation of multiplication" (National Council of Teachers of Mathematics [NCTM], 2014, p. 24). When students interpret and relate mathematical information presented in verbal and visual representations, their understanding deepens (NCTM, 2014). Further, text and trade books written for children, which can enhance engagement with mathematics (Larson & Rumsey, 2018; Radebaugh, 1981; Russo & Russo, 2018a, 2018b; Shatzer, 2008; Strain, 1969) are typically multimodal with verbal and visual modalities. Sometimes information is shared through one modality or the other, meaning that neither can be ignored if the full meaning of the text is to be constructed. In other cases, the same or complimentary information is shared through both modalities, so dual-coding of information is needed to support both comprehension of, and memory for text (e.g., Paivio, 1991; Sadoski & Paivio, 2013). In this study we examine students' mathematical understandings of multimodal text, asking: What sources and processes do third-grade students use to respond to mathematical questions about an informational text that can be answered using information from text, data display, or both?

Background and Conceptual Framework

Data displays are one important form of visual representation in mathematics education and present an interesting case because they can be viewed as a whole (e.g., combining information

from a table with that of the written text to answer a question) or as a compilation of information (e.g., combining information from different data points on a graph to draw a conclusion). When categorizing the kinds of questions that graphs can be used to answer, independent of text, Friel et al. (2001) reported three levels of data display comprehension: "an elementary level focused on extracting data from a graph (i.e., locating, translating); an intermediate level characterized by interpolating and finding relationships in the data as shown on a graph (i.e., integrating, interpreting), and an advanced level that requires extrapolating from the data and analyzing the relationships implicit in a graph" (p. 130). These levels coincide with Curcio's (1987) three levels: reading the data, reading between the data and reading beyond the data. Alongside these levels, we draw on Raphael and Au's (2005) Question–Answer Relationship (QAR) framework involving (i) right there, (ii) think and search (iii) author and me and (iv) on my own questions. From the QAR framework, we concentrate specifically on "think and search" questions, in which the information needed to construct an answer must be located in multiple parts of the text and synthesized. Parallel to this, we employ Curcio's notion of "reading between the data," which involves making comparisons or identifying relationships within a graph.

Methodology

Participants

Participants in this study were 31 third-grade students across three classrooms in a suburban, midwestern school. The school is generally considered to be academically strong, with 73% of third-grade students demonstrating proficiency on statewide math assessments (38% is the state average) and 59% doing so for English language arts (40% is the state average). The school is ethnically and culturally diverse; 47% of students identify as Asian or Pacific Islander, 35% as White, and the remaining 18% as Black, Hispanic, or two or more races. Prior to data collection, a warm-up task on sharing their thinking out loud was completed to ensure that all students were comfortable and understood how to engage in verbal protocols.

Materials

Materials used in this study included a modified two-page spread from the book *One Well: The Story of Water on Earth,* by Rochelle Strauss and Rosemary Woods (Illus.) (2007). The pages in Figure 1 were shown to students on a laptop screen, equipped with eye tracking and audio recording software to capture eye movements, fixations, and verbal explanations.

Data Collection

Data was collected using the portable EyeLink Duo eye tracker. Binocular gaze data were recorded at a sampling rate of 1000 Hz, with measurement error below 0.4%. The system recorded students' gaze behavior as they read and provided verbal protocols. Quantitative measures included the number, sequence, and duration of fixations across designated interest areas. Qualitatively, the software allowed us to merge audio and video to play back a session and watch the participant's eye gaze as they read and explore the 2-page spread. During each recorded one-on-one session, participants first explored the page spread for two minutes while thinking aloud about what they were viewing and reading. They then answered seven questions about the spread, two of which are analyzed in this study (i.e., 1. Which of the places mentioned here uses the most water? How did you figure that out? 2. What do you notice when you compare the average daily water use by people in India and North America?). If not provided spontaneously, students were also asked to explain their reasoning and sources for their answers.

Data Analysis

Data analysis started with transcribing deidentified audio recordings and separating students' verbatim answers (noting accuracy) from their explanations. Quantitative eye-tracking metrics

(e.g., fixation counts and dwell time in milliseconds) were extracted for each question using Data Viewer in the EyeLink Duo software. We also reviewed each eye-tracking video to document students' visual pathways, including areas of focus and viewing sequence. For triangulation, we began by analyzing the verbal protocols, which included both participants' answers to the questions and their explanations of their thought processes when doing so. Using this data, we drew preliminary conclusions about how participants answered the questions, then confirmed, refined, or revised those conclusions using eye-tracking videos showing where they looked while responding. We then compared our conclusions to the quantitative data (dwell time and fixation counts). The research team collaboratively analyzed all data to strengthen rigor and reliability, resolving disagreements through systematic review to reach full consensus.

Results and Discussion

Question 1: Which of These Places Mentioned Here Uses the Most Water?

Students could use text or pictograph to provide an answer to this question. In either case, the question could be a "right there" question; the correct answer did not require integration of information from multiple places. Twenty-seven out of 31 responses were correct; one was partially correct, and three were incorrect. Twenty-five students who answered correctly relied primarily on the pictograph ("reading the data," fixating on North America portion in the pictograph, $n = 262$ out of 734 fixations, see Table 1), indicating that the pictograph effectively supported accurate interpretation of the data. One student used both the text and the pictograph to answer correctly with 33 fixations on the pictograph and 10 fixations on the running text. Explaining their thought process, the student first referenced the pictograph, correctly comparing water usage across regions (e.g., North America using 55 buckets compared to lower usage in Russia, Poland, India, Nepal, Haiti, and Ethiopia) and concluded by explaining, "North America is definitely the majority, and I know Africa isn't because, I know it doesn't mention Africa but it couldn't." The student then referenced the text, explaining why it couldn't be Africa because "many of these people live in Africa and Asia that have a low water supply." One student used the pictograph and prior knowledge, and described their thought process as, "there are lots of buckets and I have seen people in North America use lots of buckets." In contrast, several

students referenced only the text, none of whom gave the correct response, suggesting that the textual information may have been confusing. From this, we conclude that, when information is available in both text and graphic form, most students will defer to the graphical form.

Table 1: Question 1 Quantitative Data

	Fixation Count	Dwell Time (ms)
Graph North America	262	96077
Graph Total	734	274678
Running Text	50	14358

Further, when the information is readily available in a pictograph, most students are able to successfully locate it quite quickly. Their eyes moved directly to the pictograph one the question had been asked, most often to the top of the pictograph, as the water usage was depicted in descending order. When students did not refer to the pictograph to answer, it was either because they looked at the pictograph, but were not sure how to read it ("I have no idea what the answer is") or technically answered correctly, using thought processes that included largely irrelevant information from the text ("North America because we have more people and other places have less people … [I found that information] on the next page").

Q2: What Do You Notice When You Compare the Average Daily Water Use by People in India and North America?

Most students responded to this question by comparing the number of buckets shown in the pictograph ("reading between the data"), as evidenced by reporting either the number of buckets (seven for India, 55 for North America) or giving the mathematical difference (48 buckets). Ten students responded only that North America used more or India used less without providing an explanation; while an additional three gave the same response and gave an explanation not provided in the text (e.g., related to population or land size). Only three students compared liters as opposed to buckets (the pictograph key stated that each bucket represented 10 liters), describing their thought processes in ways such as "so like, the difference? They use 48 more buckets than India has 70 liters; so that means it has maybe 1000 [exaggerating the difference] liters probably." These findings suggest that most students used the pictograph to make a reasonable comparison. They were able to extract data from the pictograph to respond to the question, but only three demonstrated the skill of approaching the question as a "think and search" question, integrating information from across the representation (information in the key and pictographic information). Eye tracking data confirms this: all but one student fixated at the pictograph (n = 1,021, see Table 2), while only 13 fixated on the key (n = 41), specifically.

Table 2: Question 2 Quantitative Data

	Fixation Count	Dwell Time (ms)
Graph North America	345	123753
Graph India	27	8611
Graph Key	41	14474
Graph Total	1021	386868
Text Caption	145	47210

Conclusions

Mathematics, as a discipline, is integrated into many content areas, and multiple forms of representation can be beneficial when information is provided in different embodiments. In this study, mathematical understanding was required for students to understand the full content of the text. While text comprehension is generally thought to be about understanding the words, this study highlights the importance of mathematical understanding complementing text comprehension. Related implications include the necessity of teaching, both in PK-12 and teacher education programs, that mathematical and literacy content knowledge need to be used concurrently, at times, as well as specific strategies for doing so. While the first of these is widely known (if inconsistently practiced), the second merits additional research. The connection between content knowledge (here, mathematical) and overall reading comprehension is well-established (e.g., Cabell & Hwang, 2020), however this study highlights not only the necessity of mathematical understanding, in general, but also that mathematical sense-making could be text-specific and can vary considerably between students, even those with nearly identical academic histories (i.e., same teachers, same curricula).

STUDENTS' JUSTIFICATION OF LOGARITHM RULES FROM AN APOS PERSPECTIVE

Matt F. Park
Virginia Tech
mfpark@vt.edu

Investigations have been conducted into how students conceptualize exponents and logarithms, utilizing APOS theory, particularly regarding how students justify exponent rules. Williams' (2011) thesis presents a set of codes for identifying students' conceptions of logarithms. However, a gap in the literature remains on how students justify the corresponding logarithm rules. In this paper, I present some results of such an investigation to extend her work.

Keywords: Precalculus, High School Education, Algebra and Algebraic Thinking, Advanced Mathematical Thinking

This report draws on data from my dissertation regarding how students in a complex analysis course leverage their knowledge of real-valued exponents and logarithms to reason about the complex-valued analogs. Part of my dissertation aims to describe college students' conceptions of real and complex exponents and logarithms and to compare their similarities and differences using APOS theory. In my literature review, I have come across studies examining how students justify various logarithm rules, particularly Williams (2011). Part of Williams' (2011) claim is that responses to questions about logarithm rules can be used to characterize their process or object conceptions of logarithms. However, her thesis does not report on such responses. The findings in this report contribute to the larger goal of extending Williams' (2011) framework on exponents and logarithms from an APOS perspective and provide an answer to the following research question: How do students justify various properties of logarithms, and how might their justifications differ?

In addition to investigating this research question, I also demonstrate the utility of my methodology. Because the literature on reasoning about exponents was necessary for my dissertation but was lacking in the wider research literature, I found it appropriate to extend the codes for logarithms from Williams (2011) to analogous codes for exponents. I contend that this methodology can be productive in a wide variety of APOS studies beyond the one presented in this paper.

Theoretical Framework

APOS theory is an adaptation of Piagetian notions of reflective abstraction to the context of undergraduate mathematics education by Dubinsky (1991), Asiala et al. (1997), and Dubinsky and McDonald (2001). These three papers define actions, processes, objects, and schemas and detail the mechanisms by which individuals construct them. Dubinsky (1991) refers to five methods of constructs as reflective abstractions that "Piaget found in the development of children's logical thinking" (p. 10) and adapts them to "the context of advanced mathematical thinking" (p. 11). These five are interiorization, coordination, encapsulation, generalization, and reversal. However, this last action is Dubinsky's contribution and not part of Piaget's reflective abstraction (p. 8).

Actions, processes, objects, and schemas, as the name suggests, constitute the basis of APOS theory, which concerns the construction of schemas and mental objects. The theory posits that mental objects result from sufficient reflection on processes or the thematization of schemas

(Asiala et al., 1997). According to Asiala et al. (1997), an action "is a transformation of objects which is perceived by the individual as being at least somewhat external," (p. 7) a process is the result of reflective abstraction on an action or the reversal of an existing process, and an object is a result of either "when an individual reflects on operations applied to a particular process, becomes aware of the process as a totality, realizes that actions or processes can act on it, and can construct such transformations," (p. 8) or schemas via thematization, which is defined as a schema's inclusion in other schemas. Dubinsky (1991) and Asiala et al. (1997) define a schema as a coherent collection of objects and processes and argue that the main concern of mathematics education researchers should be the construction of schemas. Although direct observation of schemas, objects, and processes is impossible, they serve as the entry point to reflective abstraction (Dubinsky, 1991).

Literature Review

To best situate my investigations within the existing literature, I adopt findings from studies that employ APOS Theory. I am primarily drawing on Williams' (2011) framework, which outlines codes for an object, process, and functional level of understanding of logarithms. Relevant to this study are the various codes she develops to characterize her participants' APOS conceptions, particularly those she deems relevant for justification tasks. Williams (2011) arrives at a set of codes for different levels of understanding of logarithms. She has five codes for an object understanding, five codes for a process understanding, and seven codes for a function understanding of logarithms. The five codes for object understanding are O-def, O-num, O-rule, O-not, and O-part. The first of these codes describes a student who understands the logarithm expression $log_a(b)$ as the unique number where $a^{log_a(b)} = b$. The second code, O-num, characterizes a student who is comfortable leaving logarithmic expressions alone and does not need to write them as decimals. O-rule is a description that applies to students who can use logarithm rules to change the form of logarithmic expressions, and O-not refers to students who adhere to notational conventions when reasoning with logarithms. Finally, the code O-part describes students who understand that logarithmic expressions have a base and argument.

Regarding process understanding, the relevant codes are P-def, P-est, and P-exp. The code P-def refers to when "the student can think of $log_a(b)$ as a process of taking the argument b, converting it to the form of a^x, and writing as the answer" (p. 42). The P-est conception refers to students' ability to use the P-def conception to estimate the value of logarithmic expressions. The P-exp conception describes students who use exponents to evaluate logarithmic expressions. Also relevant to my data are her function codes, prefixed with an "F," which describe the various ways students can conceptualize logarithmic functions. For this study, the key concept is the F-inv conception of logarithms, which conceptualizes logarithms as the inverses of exponents. Although she does not describe them as such, I also take these codes to describe object conceptions.

I extended Williams' codes to apply analogously to exponents, as these codes did not apply to exponents and there is a lack of APOS-related codes for exponents in the literature. The basis for my analogization was the inverse relationship between exponents and logarithms. At times, the analogization was straightforward. For example, an O-num conception of exponents describes students who do not need to represent exponential expressions as decimal numbers. Other times, the analogization required additional mathematical justification, such as the P-def conception of exponents. The original P-def conception concerns transforming logarithmic expressions into an exponential expression to compute them. Rather than analogizing the P-def

conception to exponents by describing a transformation into a logarithmic expression, I instead describe it as a transformation into a multiplicative expression, as that is the more standard definition of an exponent.

I also draw from the findings of Gol Tabaghi (2007), Pitta-Pantazi et al. (2007), and Weber (2002). According to Pitta-Pantazi et al. (2007) and Weber (2002), an action conception of logarithms is evidenced by calculating logarithms via explicit multiplication. According to Gol Tabaghi (2007), an action conception is also characterized by participants' use of a guess-and-check method for solving logarithmic equations. A process conception is characterized by participants who use a general rule to determine algorithms for calculating values and can solve algebra problems involving logarithms. They can interpret the various parts of the logarithm expression and use them to justify the algorithms they employ. An object conception is indicated by participants' ability to add, subtract, or compare logarithmic expressions. Finally, a conceptual understanding of the relationship between exponents and logarithms that allows them to use logarithm laws to justify exponent laws is evidence of a schema level.

Methods

As stated above, I am drawing from data for my dissertation. I approached students in a complex analysis course at a large Southern research university and offered them compensation for their participation. For each student, I conducted four interviews: two individual and two paired. I had also disclosed this interview structure to the students and asked them to name partners they would like to collaborate with. Priority was then given to pairs of students who named another volunteer to be interviewed with. The data I am analyzing for this report comes from the first individual interview. The individual interviews were semi-structured and conducted on an iPad via the Notability application. The screen and microphone recorded the participants' scratch work and utterances, and I used a webcam to record their physical actions.

The protocol for the first interview was designed to detect their conceptions of exponents, logarithms, and complex arithmetic and consisted of 7 questions. The third question of my protocol asks the participants to justify the logarithm rules $log(ab) = log(a) + log(b)$, $log(a/b) = log(a) - log(b)$, and $log(a^r) = r\, log(a)$, and the fourth question asks the participants to justify the exponent rules $(ab)^c = a^c b^c$, $(a^b)^c = a^{bc}$, and $a^{b+c} = a^b a^c$. Within the context of the wider study, these questions are designed to calibrate my analysis of their second interview and to compare how they apply the rules of exponents and logarithms in the real and complex cases. However, this paper primarily reports on their responses to questions about real logarithms in answering my research question.

I recorded the interviews using Zoom's auto-transcription feature and reviewed the audio to clean up the transcript, as the software was still imperfect at the time. The coding process consisted of multiple rounds. I first coded the student work using a codebook that synthesized multiple studies on students' understanding of logarithms, exponents, and complex analysis, primarily Williams (2011), Pitta-Pantazi et al. (2007), and Gol Tabaghi (2007). Next, I reviewed the interview transcripts and video and coded relevant utterances. In a spreadsheet, I summarized their responses to the tasks, included relevant interview excerpts, and determined which codes were relevant to the description. Finally, based on the relevant codes, I identified the highest concept that emerged at that point in the interview.

Participants

Although my data involves six participants in think-aloud interviews (Montague & Applegate, 1993), I am reporting only on the results from two students, Jim and May. Jim was a second-year math major minoring in Engineering Science and Mechanics, but by credits has

senior standing, and May described themself as "a senior double majoring in Chemistry and the traditional Math degree who has been a part of undergrad research since freshman year and doing math research since spring of junior year."

Analysis

One of the most insightful codes about May and Jim comes from Gol Tabaghi (2007). According to her, relating the exponent and logarithm rules indicates a schema that includes conceptions of both exponents and logarithms. Thus, both May and Jim's schemas of logarithms and exponents accommodated each other. This, along with the variety of conceptions on display, suggests that the conceptions at different points were heavily context-dependent and may not indicate a lack of knowledge on their part.

Jim's Conceptions

Jim first demonstrated proficiency in simplifying logarithmic expressions. When Jim was asked to simplify log_{15} (20), his immediate strategy was to rewrite 20 as $15 \cdot 4/3$, and then use a logarithm rule to rewrite the original expression as $1 + log_{15}$ (4) $- log_{15}$ (3). When pressed to simplify further, he wrote a final expression of $1 + \frac{ln4}{ln15} - \frac{ln3}{ln15}$, but indicated that he believed that the summands in the prior expression were sufficiently simplified. Williams' (2011) framework suggests that Jim demonstrated an object conception of logarithms. His flexibility in manipulation is characteristic of an O-rule conception, and his metric for appropriateness of a particular form is characteristic of an O-num conception. Furthermore, Jim's instantaneous evaluation of other logarithms suggests a process conception of logarithms according to Weber (2002).

Later, he solved the logarithmic polynomial equation $log_3 (x + 1) + log_3 (x) = 1$. His logic was the following: Because logarithms and exponents are inverses, if raising a power to the one logarithm expression yields the argument of the other, the two sides are equal. Then, he can transform the expression into a polynomial and then determine which possible values are in the domain of the logarithm to narrow down possible solutions. This implicitly uses the argument that if $a^b = a^c$ then $b = c$. Implicit use of this fact could be related to the O-def conception from Williams (2011) and is further evidence of his object conceptions for logarithms.

Jim's justifications for the logarithm rules $log\ (ab) = log(a) + log(b)$ and $log\ (a/b) = log(a) - log(b)$ were similar. In both cases, he took the sum expression, i.e., the right-hand side, and raised a number c to the power of it. By taking $c^{log(a)+log(b)}$, he deferred to properties of exponential expressions and split it into factors, giving $c^{log_c a} c^{log_c (b)}$, and stated, "because it's in the power, you can split it over addition." He then reasoned that each factor, by definition, was a and b, so the product was ab, "but then this gives you a log base c of ab from there," concluding the proof. Despite his abuse of notation, which might suggest $ab = log\ (ab)$, His utterances made it clear that he was using equal signs to indicate implication. According to Williams (2011), his appeal to exponential properties to justify logarithm rules could indicate a P-def and P-exp conception of logarithms. Thus, his responses were characteristic of a process conception of logarithms.

Despite the relative ease with which Jim justified the product rule for logarithms, his conceptions did not yield a similarly smooth proof for the rule $log(a^r) = r \cdot log(a)$. His initial strategy consisted of setting $r \cdot log(a)$ equal to some number c, and subsequently raising 10 to the power of both sides, giving the equality $10^{r \cdot log(a)} = 10^c$, and then splitting this up into $10^r \cdot 10^{log(a)}$, leading to the expression $10^r \cdot a = c$. He determined that the equality $10^{r \cdot log(a)} = 10^c$ was incorrect and wrote two expressions: $(10^r)^{log(a)} = 10^c$ and $(10^{log(a)})^r = 10^c$. From the

second expression, he simplified to get $a^r = 10^c$, and then "you can take log of both sides again, giving $log\ (a^r) = 10^c$, and that should do it." He remarked, "Because of how this is structured, I think I could go backward, but one direction flows easier if that makes sense." Notably, he used an explicit base to reason about logarithm rules, but used a general base in his prior justification. This addresses the part of my research question concerning how students justify the logarithm rules. In general, Jim used his F-inv conception of logarithms to reduce the justification of logarithm rules to a justification concerning exponent rules, which is further evidence toward a general object conception of logarithms, although his last justification suggests his object conception

Next, Jim's justifications of exponents relied on combinatorial interpretations of exponents, and he would try to reduce the general version of exponent rules to the original combinatorial interpretation. For example, when justifying $(a^b)^c = a^{bc}$, he described the left side as a^b c times, and then a^b as a multiplied by itself b times, so described a multiplied by itself bc times, which meets the definition of the right-hand side. However, when generalizing this property to rational powers, Jim did not appeal to a definition of roots because "I don't know if that relies on knowing that the root of a power can be split up." His concern about building up fully rigorous arguments for exponent properties may indicate that his schema of exponents and logarithms treats exponents as more fundamental, hence his relative lack of concern in using exponent properties to justify logarithm properties. By appealing to exponent rules and combinatorial interpretations of exponential expressions, his proofs for exponent rules indicated an operationalization of an O-rule and O-def conception of exponents. Thus, he was operating with primarily object conceptions of exponents.

May's Conceptions

May's conceptions of logarithms were varied to a similar degree as Jim's. In calculating log_{10} (1000), they determined the value to be 3 because "it's 100 times 10." Similarly, when calculating log_3 (81), they said, "Three, so twenty… seven times 3" while calculating the product of 27 and 3. When they evaluated this product as 81, they determined it would be 4 "because 3 to the 4 is 81." When asked to simplify log_{15} (20), they tried to estimate it using two approaches. The first was looking for a solution to $15^x = 20^x$, and the second attempt resulted in estimating the value to be around 5/3 by using the equalities $log(20)/log(15) = log\ (20 - 15) = log(5)$. Similar to Jim, they identified the value of $log_b\ (a)$ as the power of b that gives a and, notably, they iterated multiplication to compute logarithm values. Because their method of calculating logarithms involved explicit multiplication, their conception of logarithms would fall under an action conception, according to Weber (2002) and Pitta-Pantazi et al. (2007). However, their estimation of logarithm values falls within Williams' (2011) P-est conception of logarithms, so they had at least a process conception of logarithms.

May's justification for $log\ (ab) = log(a) + log(b)$ was similar to how Jim justified $log(a/b) = log(a) - log(b)$, but used a base of 10 instead of c, indicating an F-inv object conception of logarithms. They differed most in their justification of $log(a/b) = log(a) - log(b)$. When faced with the expression, May similarly identified $log(a/b)$ as "z such that $10^z = a/b$, and likewise identified $log(a)$ and $log(b)$ as "x, y such that…" and wrote $10^x = a$ and $10^y = b$. Continuing the proof, they realized that a/b could be rewritten as ab^{-1}, and setting $z = log(a/b)$, reasoned that $10^z = a/b$, and "applying log to both sides would give you $log(a/b)$, and then this would be $log(a/b)$ and this would be $log(ab^{-1})$." They finished the proof by saying "you could just split this up" into $log(a) + log(b^{-1})$ and then "assuming we can use the rule of powers" yielded $log(a) - log(b)$. Similar to Jim, their appeal to exponential properties to justify

the logarithm rules could indicate a P-def and P-exp conception of logarithms, rather than a general process conception.

May used induction to justify the rule $log(a^k) = k\ log(a)$. They reasoned, "that one's pretty obvious…I would just do the base case, which would be $log\ (a)$ equals, well, one times $log(a)$. Obviously, this is just 1." In justifying the inductive step, they assumed that the equality held for all natural numbers up to k, took the expression $log(a^{k+1})$, broke it up into $log(a^k \cdot a)$, and using a prior established logarithm rule, took this to be $k\ log(a) + log(a)$. Finally, they collected like terms and got the expression $(k+1)\ log(a)$, completing the proof. The ability to act on logarithmic expressions via induction is further evidence toward an object conception of logarithms. Furthermore, they operationalized logarithmic expressions as satisfying some exponential expression, which falls under an object conception according to Weber (2002) and Pitta Pantazi et al. (2007).

Some of May's justifications of exponent rules displayed object conceptions of exponents, but others relied on logarithm properties. When justifying $(a^b)^c = a^{bc}$, they used a combinatorial argument similar to Jim's, indicating similar object conceptions of exponents. But when justifying the rule $a^b a^c = a^{b+c}$, they applied the logarithm to both sides, yielding the expression $log(a^b) + log(a^c) = log(a^{b+c})$. They then used another logarithm rule to get the expression $b\ log(a) + c\ log(a) = (b+c)\ log(a)$, and then canceled out $log(a)$ to 1. When asked about the differences in justifications, they said, "If you had asked these in a different order, I might have given a different answer," suggesting a stronger relationship between their schema for logarithms and exponents. The combinatorial reasoning for the former rule and their calculation of logarithm values suggests that they can reason about the other exponent rules combinatorially and were strongly influenced by the task order. This response also addresses the part of my research question concerning how students justify the logarithm rules. Broadly speaking, the use of the inverse relationship of exponents and logarithms demonstrates a P-exp conception of exponents and logarithms.

Discussion

This analysis of May and Jim's responses provides an answer to my research question: How do students justify various properties of logarithms, and how might their justifications differ? In summary, May and Jim's conceptions of logarithm and exponent rules were similar in terms of what conceptions were present, but differed considerably in how they were organized. May and Jim demonstrated similar process and object conceptions of exponents and logarithms in a unified schema until they were asked to justify the properties. Whereas May justified logarithm and exponent rules in terms of each other, Jim sought to justify exponent rules combinatorially and with an explicit interpretation of exponents as iterated multiplication. More broadly, both May's and Jim's schemas for exponents and logarithms have coalesced into a single schema. So a description for a college student's conceptions of logarithms is very likely incomplete without accompanying descriptions for exponents. My interview protocol, which addressed both logarithms and exponents, provided me with a broader context for their justifications. In particular, May's sensitivity to task order seemed to confirm my hypothesis that participants' thinking could be significantly influenced by the ordering of the tasks in the interview. Their circular reasoning may indicate an exponent/logarithm schema that contains an object conception of logarithms independent of exponents. Contrast this with Jim, who was less affected by the order of tasks but was compelled toward a more fundamental justification of exponent rules over logarithm rules. Thus, his object conceptions of logarithms were built on top of and attached to his conceptions of exponents.

More specifically, the differences in proofs indicate some variations in their respective schemas. Jim relied solely on the interpretation of iterated multiplication to justify exponent rules. Later in the interview, he attempted to reduce the justification of fractional exponent rules to the case of integer exponent rules. He likely operationalizes definitions when justifying properties of exponents and logarithms. He will likely justify the properties of the complex exponent and logarithm by referring to their definitions and to the inverse relationship between the exponent and logarithm. In contrast, May's use of logarithm rules to justify exponent rules suggests that in the complex setting, they are less likely to refer to exponents when justifying properties of the complex logarithm.

Broadly, the different ways May and Jim engaged with the justification tasks may have broader implications for instruction. It is worth considering the different affordances of each approach. While Jim's approach may qualify as more "rigorous," I find it noteworthy that his insistence on such strict adherence limited some of his willingness to perhaps reason more powerfully. In comparison, May may not adhere to the strictest standards of "rigor," but their flexibility enabled them to have a comparatively easier time justifying real logarithmic rules. This contrast between May and Jim raises questions about the role of rigor in different types of mathematical discourse. Particularly in a teaching context, it is worth considering when rigorous thinking is prioritized over more powerful thinking, and how students' expectations fall on this spectrum.

In terms of research implications, this phenomenon suggests that similar conceptions of exponents do not necessarily imply similar conceptions of logarithms, with both research and pedagogical implications. The implication for research is as follows: Among college students, the schema for exponents and the schema for logarithms are likely unified into a single schema. However, conceptions relating to exponents are likelier to be homogeneous compared to conceptions for logarithms. Thus, to fully describe a student's conceptions of logarithms, it is necessary to describe their conceptions of exponents as well.

Conclusion

In Williams' (2011) study, she described the limitations of her codes through a participant, Mark, who demonstrated that her framework "does not necessarily help separate good understanding from exceptionally good understanding" (p. 63). She attributes this to a variety of factors, most notably his job as a math tutor. He had a proof of the product/sum rule as follows:

$$log(ab) = log(10^{log(a)} \cdot 10^{log(b)}) = log(10^{log(a)+log(b)}) = log(a) + log(b)$$

Like May and Jim, Mark presents a straightforward proof, but unlike Jim, he moves from multiplicative expressions to additive expressions. That is, he reasoned in the opposite direction from what Jim stated: "flows easier."

In this investigation, I have made two discoveries. The first concerns the nature of college students' cognition when justifying exponent and logarithm rules, and more generally, their cognition regarding high school mathematics. The second discovery concerns the fruitfulness of extending pre-existing APOS codes to larger domains to address gaps in existing literature.

Regarding the first discovery, I have found that advanced college students approach precalculus questions in at least two ways. The first is emblematic of Jim's behavior, in which he was careful to make rigorous arguments and to rely on a proof template. The second is emblematic of May's behavior, in which they were willing to use a variety of proof techniques, including induction. I attribute both Jim's and May's response patterns to the higher standards of college mathematics, despite the stark divergence between the two. I conjecture that college mathematics impressed upon Jim a certain standard of mathematical rigor, while for May, it

impressed upon them the far-reaching utility of proof techniques. In pedagogical terms, this suggests that students may be receptive to multiple styles of mathematical presentation. It is worth considering the utility of strict rigor in undergraduate mathematics if it misaligns with student thinking.

Regarding the second discovery, my findings suggest that one way to address Williams' (2011) limitations is to describe students' conceptions of exponents. The two college students' schemas for logarithms and exponents were closely related. It was necessary to explore their conceptions of logarithms and exponents to model their justification of various properties of these operations, as they were using reasoning about exponents to justify logarithm rules. It was productive enough to extend pre-existing logarithm codes by creating analogous codes for exponents.

More generally, I have demonstrated the viability of extending APOS codes of a particular mathematical concept to other domains, despite a lack of existing literature. In general, when describing possible conceptions of operations that are mutual inverses, for every conception of one operation, it may be viable to have an analogous conception for the inverse operation as an a priori conception. Examples include multiplication and division, as well as derivatives and integrals. I am also adopting another method for analogizing existing APOS codes. As stated earlier, this investigation was initially motivated by an interest in understanding how college students understand complex exponents and logarithms. I am analogizing Williams' (2011) codes to these mathematical objects and finding them similarly useful. Thus, potential APOS studies for subjects such as linear algebra over the real numbers have immediate implications for linear algebra over the complex numbers, and investigations into students' cognition of a given topic may have implications beyond their immediate subject.

AUTHORSHIP AS CONTRIBUTION: CIRCULATING STRATEGIES THROUGH FACILITATION

Leslie Yuqui
Northwestern University
leslieyuqui2029@u.northwestern.edu

This study examines how facilitation moves within the How Many routine supports collaborative mathematical thinking in a third-grade classroom. Drawing on positioning theory, the analysis highlights how the facilitator structured opportunities for students to share, extend, and take up one another's ideas. A central contribution is the identification of facilitation practices that establish authorship to student work by publicly recognizing and sustaining students' recurring strategies as reusable classroom resources. Through this practice, student-generated ideas became collectively available and supported shifts from unitary counting toward more sophisticated composition strategies. Together, these practices repositioned authorship from individual ownership toward shared intellectual contribution.

Keywords: Positioning Theory, Authorship, Facilitation Moves

Supporting students in developing mathematical understanding requires more than eliciting correct answers—it involves cultivating classroom communities where student ideas become the primary resource for learning. In discussion-rich environments, students learn by collectively building on one another's reasoning (Chapin et al., 2009; Forman et al., 1997; Michaels et al., 2008). These pedagogical practices contrast with traditional school mathematics, where knowing is defined by speed and rule-following, and primary intellectual authority resides with the teacher and textbook, limiting students' opportunities to generate or critique ideas (Clement, 1991; Kooloos et al., 2022; Lampert, 1990). As a result, whole-class discussions have too often been confined to "show and tell" formats, where students present correct solutions in isolation, with minimal attention to conceptual connections or collective sensemaking (Stein et al., 2008). Research on mathematically significant pedagogical opportunities emphasizes the importance of leveraging student thinking as a resource for collective learning (Leatham et al., 2015; Van Zoest et al., 2017).

This study draws on positioning theory (Harré & Van Langenhove, 1991; Herbel-Eisenmann et al., 2015) to explore how teachers position students during classroom discourse to foster authorship and the circulation of mathematical ideas. Positioning theory conceptualizes social interactions as dynamic processes in which individuals are ascribed or take on particular roles, rights, and responsibilities (Drageset & Ell, 2024; Herbel-Eisenmann et al., 2015). These positions are not fixed; rather, they are negotiated through language, actions, and broader discursive patterns. In mathematics education, this perspective highlights how teachers' facilitation moves can shape who is recognized as a knowledge contributor (Tait-McCutcheon & Loveridge, 2016), whose ideas are amplified, and how ideas travel across the classroom. Authorship can thus be understood as a socially positioned phenomenon: students are positioned as authors when their ideas are treated as valuable, novel, and when their intellectual ownership is publicly recognized.

Building on this conceptualization, the exploratory study investigates how facilitation moves within a visual number-sense routine support the development of authorship by publicly recognizing and sustaining students' mathematical strategies. Prior research has conceptualized authorship in mathematics classrooms as students generating original ideas and using their voices

to question and make sense of what they are learning, framing authorship as exclusive (Povey, 2003). In these accounts, authorship is closely tied to individual expression or intellectual ownership. Extending this work, the study views authorship as a socially constructed classroom practice, in which it is not only about generating original ideas but also about how those ideas are encouraged for further development and uptake. Accordingly, this study addresses two research questions: (1) How does teacher facilitation of mathematical discussions promote authorship of mathematical strategies? and (2) How do students take up ideas authored by their peers?

Methods

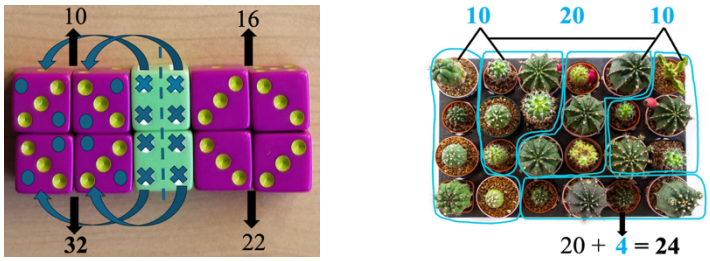
Context, Participants, and Design

The study was conducted in four rural Midwestern classrooms—two second-grade and two third-grade classrooms. The intervention included one week of pre-interviews with 32 students, three weeks of instructional sessions, and one week of post-interviews. Gwen, a mathematics educator and researcher, facilitated three 30-minute lessons per week in each classroom, resulting in 36 total lessons (nine per classroom). The *How Many* instructional routine used in the intervention consisted of three components: (1) displaying an image and asking students, "How many do you see?," (2) providing think time, and (3) facilitating a whole-class discussion that highlighted a range of strategies and justifications. Each lesson incorporated one or two images from the Multiplicity Lab (www.multiplicitylab.org) designed to elicit multiple solution paths, and three images were used during student interviews.

Data Sources and Analytic Approach

Data included video recordings and transcripts of whole-class discussions and pre- and post-interviews. Although the project included four classrooms, this paper focuses on one third-grade classroom to examine how facilitation moves positioned students as authors of mathematical ideas and how peers took up and circulated those ideas. Three lessons (1, 2, and 7) were selected for in-depth qualitative analysis based on their potential to address the research questions.

Analysis proceeded in three phases. Initial coding focused on (1) teacher prompts and facilitation moves, (2) student strategies and reasoning processes, and (3) how ideas were extended, revoiced, or collectively elaborated. Codes were then iteratively refined to identify patterns in how participation structures and mathematical reasoning co-evolved across lessons. Particular attention was given to moments when a strategy shifted from an individual contribution to a publicly recognizable and reusable classroom resource. Through this process, a focal case was identified: Ian's "making 5s" strategy. This case was selected because it illustrated how a student-authored idea surfaced in discussion, was publicly recognized through facilitation, and was taken up by peers. The strategy was then traced across subsequent lessons to examine how it contributed to collective mathematical sensemaking over time.



Findings

This study found that Gwen's facilitation positions students with authorship through three key moves: (1) treating partial ideas as resources and physically positioning students as contributors, (2) naming and attending to unexpected strategies as opportunities for sensemaking, and (3) reinforcing students' ownership of strategies through anticipation and public attribution.

First, the teacher positions students as authors by framing their developing ideas as valuable while maintaining their public presence in the discussion. Early in Lesson 1, Gwen began to set in motion a routine in which incomplete ideas were opened for collective work rather than evaluated for correctness. When Yahaira began grouping doubles—pairing equal dots, such as 3 and 3—on an image of multiple dice without computing the total, Gwen did not finish the

strategy herself or shift attention elsewhere. Instead, she invited a student, Steven, to help extend the reasoning toward a solution while keeping Yahaira at the board: "Stay up here … so we're using your thinking and your strategy." This facilitation move accomplished two things. It treated Yahaira's partial reasoning as a resource worth building on, and it maintained her spatial and intellectual presence as Steven contributed. Gwen further reinforced this positioning by asking Yahaira to evaluate how a classmate extended her idea. In this exchange, mathematical progress unfolded as a connected sequence of contributions rather than an individual performance. By preserving both attribution and physical positioning, Gwen established a pattern in which student ideas could be shared without becoming detached from their originators—laying the groundwork for later moments when strategies traveled across tasks and time.

In the second facilitation move (Lesson 2), Gwen named and elevated an unanticipated strategy as a learning opportunity. Gwen overheard Ian say that he had "made fives;" although she had planned to transition to a new image, she paused and told the class she was "kind of curious" about his thinking. This instructional pivot signaled her willingness to let a student-generated idea redirect the lesson. At the board, Ian explained how he split the two green dice and redistributed the dots to form groups of five—restructuring the image in a way that was neither immediately visible nor an intended feature of the task (see Figure 1a). His strategy reflected an early example of decomposition, as he adjusted quantities to make the computation more manageable. This reorganization allowed him to count more efficiently, moving clockwise around the image to reach a total of 32. Gwen responded, "But by making fives … that's really cool," publicly marking the strategy as both novel and mathematically powerful. By attending to student thinking, Gwen positioned Ian as an author of a mathematical idea and created space for classmates to explore, question, and potentially adopt the approach. Her explicit naming of "making fives" turned it into a shared focus that ultimately circulated within the classroom community, serving as a bridge to more sophisticated mathematical reasoning.

(a) (b)

Figure 1: Ian's Making 5s Strategies

Finally, building on the visibility of Ian's strategy, Gwen enacted a facilitation move in Lesson 7 that reinforced his ownership through anticipation and public attribution. When Ian was called to the board to show his thinking for the cacti image (see Figure 1b), Gwen deliberately drew the class's attention to an emerging pattern she had noticed across previous lessons—that Ian consistently organized quantities by making 5s. Before Ian began, she asked the students to predict what he might do, "based on what he's done before." Students confidently responded, "He's going to do fives," signaling that Ian's strategy was widely recognized and had entered the classroom's collective repertoire, positioning him as its author. During the cacti task, Ian organized the image into four groups of five—starting with the "L"-shaped cluster on the left and

forming a final group of four at the bottom (see Figure 1b). Classmates reacted enthusiastically, calling out "Fivesss!", "Viola!", and clapping. Gwen affirmed these reactions and later summarized, "A lot of friends already predicted that Ian will look for fives—he likes to look for fives." Through this public recognition, Gwen explicitly established the association between Ian and the strategy, while signaling that the approach remained available for collective use. At this moment, authorship functioned relationally: students learned not only a mathematical strategy, but also how to notice, remember, and flexibly apply it across contexts—from the original dice tasks to a more real-world array.

Student Engagement with Authored Ideas

Students responded to this culture of authorship in two primary ways. First, when prompted by the facilitator, they extended one another's ideas. Gwen's invitation to build on Yahaira's partial strategy was not an isolated event; across the dataset, students completed one another's thinking multiple times. Second, students independently took up and adapted a peer-authored strategy in their own work in subsequent lessons. Ian's "making 5s" approach became increasingly visible across activities. In one instance, a student named Angel composed quantities into fives—"four plus one equals five," "three and two equals five"—while annotating a dice image. Classmates immediately recognized the structure of the approach, calling out, "He's going to use 5s!" and describing it as a smart idea. Importantly, toward the end of Angel's explanation, Gwen reframed the discussion to emphasize the reuse of strategies as a productive norm, explaining that discussing strategies allowed the class to "pick up on other ways" and try them later. This moment illustrated a key mechanism of diffusion: once a strategy became publicly recognizable, peers could identify, name, and take it up as a shared intellectual resource.

Discussion

The teacher in this case study used a suite of facilitation moves to position students with authorship, ultimately supporting a learning environment in which students could build on and take up one another's thinking. These moves repositioned authorship from *authorship-as-exclusivity* to *authorship-as-contribution*. Authorship-as-exclusivity positions ideas as belonging solely to an individual—fixed, private, and disconnected from the classroom's collective work. In contrast, authorship-as-contribution frames ideas as both attributable and shareable: students are recognized as the originators of strategies, yet their ideas circulate, evolve, and become resources for supporting efficiency, flexibility, and creativity in others' reasoning. Not all ideas circulated in the same way; although doubles were more commonly used overall, Ian's "making 5s" strategy circulated more widely, which may be due to its novelty drawing more collective attention than familiar approaches like Yahaira's grouping of doubles. Importantly, this diffusion was not accidental, Gwen paused during the transition to acknowledge Ian's strategy, positioning it as worthy of collective attention. Such moments illustrate the importance of teachers discerning which student ideas to center and amplify (Tait-McCutcheon & Loveridge, 2016; Van Zoest et al., 2017). The impact of this positioning extended beyond the instructional routine itself: in post-interviews, several students referenced Ian by name and demonstrated increased strategic flexibility, suggesting that authorship had become socially recognized and instructionally consequential. Future research should investigate how positioning students' unexpected ideas with curiosity and intentional authorship shapes strategy development and fosters ongoing innovation.

IMPLEMENTING PROBLEM OF THE WEEK WITH ELEMENTARY LEARNERS

Mindy Melgar
University of Southern California
melgarm@usc.edu

Lili Zhou
California State University, Los Angeles
lzhou18@calstatela

Keywords: Elementary School Education, Identity and Agency, Informal Education, Problem-Based Learning

Inspired by Michael Golomb's long-running Problem of the Week (POW) initiative at Purdue University, which engaged students and faculty and drew international participation, the first author launched a reimagined Problem of the Week at elementary school settings. While inspired by the original model, our initiative intentionally shifted the design to better serve K–5 learners. Specifically, we grounded our work in the principle of Low Floor, High Ceiling tasks (Boaler, 2015): problems with multiple entry points that are accessible to all students while allowing for increasingly sophisticated strategies and extensions.

Study Design and Context

Each Problem of the Week is designed to elicit a range of strategies. Students are encouraged to select the tasks and extensions with which they wish to engage, reinforcing agency and mathematical identity. Importantly, the problems are intentional designated without being tied to a specific grade level. A single task might be solved through various strategies, such as direct modeling, number sentences, table creation, or pattern recognition. This structure allows students across grade levels to engage meaningfully with the same core task (Zhou, 2025).

Beyond solving the problems, we provide open-ended prompts to further facilitate mathematical discourse (National Council of Teachers of Mathematics [NCTM], 2014). The prompts are used, such as: "What do you notice? What do you wonder?" "How are they alike and different?" "Which one doesn't belong?"

In the focused elementary school, problems are distributed every other week. On alternating weeks, student work is displayed publicly in a central campus location that all students pass multiple times daily. The display emphasizes diverse strategies rather than "right answers," and student names are prominently featured to honor authorship and thinking.

Data Source and Preliminary Findings

We maintain a participation spreadsheet to track submissions and distribute recognition pins. Participation has increased consistently since the implementation of the redesigned model in 2023–2024. Average submissions per problem increased from 35 in 2023–2024 to 41 in 2024–2025 and 55 in 2025–2026. Similarly, the proportion of students participating school-wide rose from 47% in 2023–2024 to 59% in 2024–2025 and 63% in 2025–2026. These trends suggest increased student engagement, particularly among younger learners.

We have also collected family feedback, which further suggests that the Problem of the Week engages students who do not typically identify strongly with school mathematics. For instance, one parent described her child as a "spatial thinker". Preliminary evidence suggests that the reimagined Problem of the Week fosters broad participation, strengthens mathematical identity, and builds a visible culture of collective mathematical brilliance. Public celebration of varied strategies, multilingual access, and low-stakes entry points appear to contribute to increased engagement across grade levels and learner profiles.

DESIGNING UNCERTAINTY TO SUPPORT PROCEDURAL FLEXIBILITY IN MATHEMATICS LEARNING

Objectives and Purpose of the Study

Grappling with uncertainty in mathematics is an important but under-explored aspect of students' participation in complex mathematical tasks such as error analysis or mathematical debugging. Uncertainty has traditionally been considered a hindrance to effective learning in mathematics education. However, uncertainty can be a productive resource that facilitates deep mathematical reasoning, provided it is intentionally designed and pedagogically supported (Baker et al., 2020; DeBellis & Goldin, 2006; Zaslavsky, 2005). From this perspective, the aim of this poster is to propose a developing conceptual framework that describes how uncertainty is intentionally designed into error analysis tasks to support mathematical learners' development of procedural flexibility. Specifically, this poster revolves around the following two questions:

- RQ1. How can uncertainty be intentionally designed into math error analysis tasks?
- RQ2. In what ways can learner interactions with designed uncertainty support procedural flexibility development?

Theoretical Framework

Zaslavsky (2005) conceptualized uncertainty as a key element of a mathematically rich task and showed that situations involving conflicting arguments, ambiguous conclusions, and results that are difficult to immediately verify lead learners to engage in higher-order mathematical thinking. In this sense, uncertainty acts as a catalyst for shifting procedural knowledge from mechanical performance to adaptive and flexible mathematical reasoning (Radatz, 1979; Star, 2005).

Error analysis tasks become a key means of designing this uncertainty. Radatz (1979) argued that mathematical errors should be understood as meaningful products generated in the learner's cognitive process, not as simple mistakes. Purposeful inclusion of uncertainty requires learners to check and reconstruct their reasoning processes rather than rely on formalized procedures and automated solutions. For example, presenting learners with two different solutions to the same problem and asking them to determine which is correct, or whether both are valid, implies uncertainty that is difficult to verify immediately and allows the learner to deeply explore the meaning of the procedure. Rushton (2018) reported that students who participated in error analysis-oriented classes showed higher achievement in delayed post-testing than those who participated in traditional classes.

Conclusions and Implications

Uncertainty can be designed through error analysis tasks, and this designed uncertainty functions as a medium that leads learners to develop flexible mathematical reasoning beyond performing mechanical procedures. We posit—and intend to explore in future studies—how these mechanisms can be realized through the role of teachers in planning and coordinating students' work with uncertainty and error analysis.

ARBITRARY TO RATIONAL COORDINATION: A TYPOLOGY OF MATHEMATICAL CONVENTIONS

Ingrid Ristroph
University of New Hampshire
ingrid.ristroph@unh.edu

Keywords: Communication, Cognition, Mathematical Representations, Reasoning and Proof

Introduction

Hewitt (1999, 2001a, 2001b) characterized the mathematics curriculum as divided into two domains: (1) "the arbitrary"—the conventional names, notations, and agreed usages enabling consistent communication about mathematics—and (2) "the necessary"—the rules, relationships, properties, and procedures that can be logically deduced or derived. Here I build on this delineation by proposing that the first category of conventions is not homogeneous: some are largely arbitrary choices; others persist for their efficiency, simplicity, or coherence within existing systems or practices, stabilized through processes of *rationally coordinated equilibria*. I call this the *Arbitrary-Rationally Coordinated Mathematical Conventions Gradient.* Additionally, I propose a typology of mathematical conventions that differentiates by function and by which the gradient of arbitrariness can be superimposed.

Typology of Mathematical Conventions

The typology identifies six disciplinary categories and a seventh, schooling-specific category.

I. Notational and Symbolic: symbol choices (x, y, z; π; $\sum$), abbreviations ("sin," "log"), and structured notation (fractions, exponents) settled through communal use.

II. Representational: graphs, coordinate systems, and diagrams governed by spatial norms (e.g., horizontal abscissa, anticlockwise rotation, planar diagrams of knot crossings) that mediate access to mathematical structure.

III. Measurement and Quantification: units, derived quantities (slope as "rise over run", velocity), and zero points/scales (e.g., Celsius vs. Kelvin) that afford intersubjective comparison.

IV. Procedural and Computational: order of operations and algorithmic layouts (e.g., long division), which persist as culturally entrenched even where alternative methods exist.

V. Linguistic and Discursive: disciplinary phrases ("without loss of generality") and cultural naming practices (e.g., Pascal's vs. Yang Hui's Triangle).

VI. Epistemic: proof methods and negotiated standards of rigor that govern what counts as acceptable justification.

VII. Schooling-Specific Pedagogical: locally produced conventions (e.g., PEMDAS, FOIL, "T-charts") that scaffold recall and classroom communication but are absent from global practice; conflating these with disciplinary conventions can contribute to student confusion (Karp et al., 2014; Ristroph, 2025).

Contribution and Implications

Classroom practice often treats conventions as mathematical truths "fallen from the sky" rather than as arbitrary human decisions or as socially rational, stabilized choices (Ristroph, 2025). This proposal offers a typology that makes conventions visible and differentiable, giving educators and researchers a tool for identifying mathematical and pedagogical conventions and aiding in the explication of rationales.

In this year-long constructivist teaching experiment session, we examine how two fourth-grade students with intensive supports in mathematics reorganize their whole number understandings to construct fraction understandings. We consider how each student's iterating and partitioning change to indicate how each student demonstrated their progression. Dalton mainly developed his whole number and fraction understandings in tandem with each other, as he did not have a units structure to fully reorganize. Dalton's ability to map fractions iteratively and utilize his halving and doubling provided him opportunities to reason more robustly in fraction tasks. Angela primarily reorganized her whole number activity with each shift in her iterating and partitioning development. This allowed her to refine and reverse her whole number activity when developing fraction understandings in a multiplicative manner.

Keywords: Number Concepts and Operations, Rational Numbers and Proportional Reasoning, Students with Disabilities, Elementary School Education

Children, including those with Intensive Supports in Mathematics (ISM), iterate and partition when solving fraction tasks, which can be leveraged to support future fraction development (i.e., Hunt et al., 2016). Preliminary work has also showcased that children with ISM develop partitioning through their iterating and vice versa when developing fraction activity from their whole number activity (MacDonald et al., 2025).Yet, it is still not clear how children with ISM reorganize their whole number iterating and partitioning activity to inform their fraction development over long periods of time. The focus of this article is to explore the year-long conceptual development of two fourth-grade students with ISM as they engaged in whole number and fraction iterating and partitioning.

Theoretical Framework

We framed our study around children's development of constructs that make up their mental models or schemes (von Glasersfeld, 1995). Modeling children's activity with scheme theory allows attending to changes in children's understandings (accommodation of schemes) and identifying connections between children's understandings (assimilation of schemes), giving us insight into utilizing children's actions (e.g., partitioning; iterating) and goals when describing children's mathematical development (von Glasersfeld, 1995).

We use scheme theory to explain the units coordination that student with ISM construct,

accommodate, and assimilate when solving whole number and fraction tasks (cf. Boyce et al., 2024). Within scheme theory, a *scheme* includes an experiential situation, a goal, anticipated actions, and expected results (Steffe & Olive, 2010). When children reorganize one or more of these components, accommodation reflects a qualitative shift in how they coordinate units, rather than simply a change in procedure. This framing allows us to examine how students with ISM reorganize their unit relationships over time. We know that through their activity and experiences children first develop units by abstracting a one-ness (Ulrich, 2015), which marks the beginning of children treating quantities as units with the potential to iterate rather than perceptual collections. To coordinate their units, children organize relationships between units they construct through the composition and distribution of units. When children assimilate their schemes, they develop structures of units, resulting in anticipatory actions (cf. Tzur, 2007).

Steffe (2001) found that children reorganize their unit relationships and unit structures to construct fraction understandings. This reorganization of units provides resources for children as they begin to construct similar types of units in their fraction activity and abstraction. Fraction schemes require coordinating a whole, a fractional part, and the relationship between them simultaneously, often demanding more sophisticated levels of unit coordination than whole-number activity. As children reflect on the results of their engagement with fractions, they accommodate or assimilate their schemes, allowing them to begin developing units in units (in units) organizations (Boyce & Norton, 2017).

This reorganization of units draws on children's iterating and partitioning of units. Iterating and partitioning are not merely external procedures but are central to conceptualizing number, quantity, and arithmetic operations (Empson & Levi, 2011). For instance, engaging in partitioning allows children to make sense of division, fair sharing situations, and unit fractions by constructing equal partitions. Similarly, to mentally reconstruct wholes from unit fractions or smaller units, children need to engage in and make sense of iterating. According to Steffe and Olive (2010), the process of partitioning and iterating becomes operative when children act on mental images of these quantities by anticipating both the number and size of parts before enacting (performing) partitioning or iterating. Moreover, at this stage of development, children can also reverse the iterating and partitioning process to reconstruct the whole. Furthermore, Hunt and colleagues found iterating and partitioning are insightful activities to focus on when examining fraction development that students with ISM demonstrate (Hunt et al., 2023; see also Silva et al., 2023). Similarly, research in children's early whole-number development demonstrates that composing and decomposing quantities (Baroody, 1987), conceptual subitizing number (Bajwa, et al. 2023), and counting-on reflect emerging iteration and partitioning of composite units.

Methods

This paper utilizes a Constructivist Teaching Experiment Methodology (Steffe & Thompson, 2000), examining the activity evidenced by two fourth-grade children with ISM, Dalton and Angela (both pseudonyms), engaged in 14 teaching experiment sessions involving whole number and fraction tasks. We employed a teaching experiment methodology due to our interest in children's interactions with both the interviewer and the features of each task. These interactions provided insight into how particular mathematical behavior (i.e., physical activity, gestures, language) reflected Dalton's and Angela's whole number and fraction scheme relationships. As such, before each interview session, we refined tasks in response to data analyses of prior interview sessions to better make visible the conceptual resources each student was constructing in relation to their developing whole number and fraction scheme relationships.

We purposively selected Dalton and Angela because they were currently receiving Tier 3 mathematics instruction. Additionally, through discussions with the classroom and special education teachers at a participating school, we purposively recruited both children due to their ISM eligibility and Angela's working memory differences (the school district indicated Angela scored significantly below the norm as measured by the Woodcock-Johnson IV Cognitive Abilities assessment; Woodcock et al., 2003). Angela's working memory differences were further verified using a working memory assessment that measured participants' ability to orally repeat sequences of numbers forwards and backwards (i.e., forwards and backwards digit spans). Dalton demonstrated relatively more success in repeating the sequences than Angela. Whereas Angela struggled to repeat sequences in the order provided and was unable to repeat them in reverse. At the time of the study, Dalton and Angela were in the fourth grade, enrolled in a small rural school in the midwestern portion of the United States.

Over the course of the 2023–2024 academic year, the second and fifth author worked with the children as a pair for sessions 2–8, and 10–16, with sessions 1, 9, and 17 conducted individually to assess each student. Each 30-minute session took place throughout the school day and aligned with topics and content taught previously and/or concurrently. Each session was video/audio recorded with two cameras, each focusing on a child's engagement with the task. Each of the sessions included one whole number task and one fraction task. This structure allowed children to engage with tasks and, in particular, engage and reveal their whole number and fraction reasoning within a comparable timeframe. We drew from research-established tasks (i.e., Tzur et al., 2021; Wright et al., 2011) to ground the tasks and activities for each session. We designed tasks on a weekly basis, following our analysis of each session (conceptual analysis) as well as cross-session discussions during retrospective analysis.

Immediately following each session, a graduate student transcribed the data, which we reviewed and edited prior to analysis. We then conducted conceptual analyses and adapted subsequent tasks in response to our interpretations of children's conceptual resources, including their operation development, emerging schemes, and interpretation of each task.

Our conceptual analysis also examined transcripts for changes to their schemes to understand possible activity-effect relationships and degree of abstraction (participatory and anticipatory). Excerpts in this manuscript indicate the child by their pseudonym, "Dalton" or "Angela," and the Researcher working with the child(ren) as "Researcher."

Results

To explore how Angela and Dalton evidenced particular iterating and partitioning relationships over time between their whole number and fraction understandings, we first examine how each student developed their iterating and partitioning activity in both whole number tasks and fraction tasks over the course of the teaching experiment sessions.

Relationships Between Dalton's Whole Number and Fraction Understandings

Early in the teaching experiment sessions, Dalton demonstrated capabilities to organize units with multiple gestures (i.e., pointing, head nodding) and physical activity (i.e., finger counting, counting with manipulatives). For instance, in Teaching Experiment Session 3, Dalton was working with Angela to solve the task, "*Here are 3 plates of 6 cakes. Now look away.*" [Place out four more plates of cakes under a screen]. "*There are 4 more plates of 6 cakes under here. How many cakes are there altogether?*" Both participants were first asked how they might solve this task without any materials before being given cubes and paper plates to solve this task. At first, Dalton counts the visible cakes on the computer screen by pointing with his fingers and then continues by looking at a number strip hanging in the classroom and keeping track of the

groups and number in each group with his fingers. This results in Dalton losing track of the number of groups, pressing him to start over and recount. To alleviate any frustration, both researchers provide him and Angela with cubes and paper plates to check their solutions. In the following excerpt, Dalton uses physical activity to distribute groups of six across four plates before counting the total number of cubes.

Researcher:	And what did you say?
Dalton:	[Counting his cubes.] Twelve.
Researcher:	Okay. You whispered it to yourself, but… mhm… Dalton, can you tell me what you're doing?
Dalton:	So, I did six groups, and then I put those together, and that was 18.
Researcher:	Okay.
Dalton:	And then I am doing six more groups, and I am going to do, and then I'm going to add all those up…
Researcher:	Okay, so when you say you make six groups, why are you making six groups?
Dalton:	Because there are six on each plate.
Researcher:	Okay. So, what does this represent?
Dalton:	One. One plate.
Researcher:	Okay, perfect. And how many total plates are you going to have?
Dalton:	[Dalton is grouping his cubes.] Four, so yeah four. One, two, three, six. One more. One, two, three, four, five, five, six. One more…

As Dalton solves this task, he utilizes multiple means to count cubes and fingers and keep track of groups of six by grouping cubes. This count all is quite rudimentary but allows him access to groups through his physical counting and reflection on the groups and the number of groups he constructed. Moreover, when Dalton is counting and grouping his cubes, he counts the first group with some halving/doubling activity (i.e., "One, two, three, six"), suggesting he is beginning to partition through some halving activity and then iterate through some doubling activity to develop the groups of six.

In the same session, Dalton is given the task, "*Estimate the size of one fair share if the strip is shared among ten people*." In Session 2, the students were given the same task but asked to share the strip of paper among five people. So, at the beginning of this session, we provided these shares to the students and asked both students how they could use the share they created for five people to help them create a share for ten people. Angela simply understood that the share should be smaller for ten people, but could not tell the researchers how much shorter, and suggested they use a trial-and-error type of strategy. Dalton struggled with the question until given a fair-share context for the question: "*If I gave you a KitKat bar and you had to split that with 5 people would you get the same amount then if you split it with 10 people?*" Dalton agreed with Angela that it would not be the same amount and that the share would be smaller. However, like Angela, he struggled to explain how much smaller this share should be for 10 people. Upon seeing Angela test out the share she creates by iterating this across the paper strip (representing the whole), Dalton explains that he is going to do "basically the same thing". As such, in the following excerpt, Dalton then iterates his share across the paper strip, counting each iteration. Halfway across the strip of paper, he pauses.

Dalton:	One, two, three, four [iterating his share across the paper strip].
Researcher:	Okay. So, looking at this, Dalton, do you think you're going to be able to

	…, you said how many are here? Okay, so how many more do you need?
Dalton:	five, … four, ten, five. [Dalton is counting the shares he iterates as he draws them on the paper strip.]
Researcher:	Five more? Do you think so? You're looking at this [referring to the paper strip Dalton is distributing his share across]. Do you think you're gonna have enough space for five more?
Dalton:	Yeah.

Here, Dalton is reasoning quantitatively about half of the paper strip and possibly doubling the five to make sense of what space he has left of the paper strip to iterate five more to create ten shares. This echoes what he has done in the whole number task, as he was halving through his partitioning activity before doubling through his iterating. In many ways, this activity also allows his to create two equal groups of five, similar to his creation of four equal groups of six in the whole number activity.

In Teaching Experiment Session 13, Dalton and Angela are given the fraction task, "*So at the fudge factory, I have this big, long slab of fudge."* [Researcher puts a strip of paper in front of both students]. *"Okay?"* [Dalton is moving his head up and down]. "*One slab of fudge, and they're poured into cooling trays. Once the fudge is cooled, the workers slice the slab of fudge into an equal number of parts and put those pieces into the display cases in the store. Carlos came into the store and selected* $\frac{2}{8}$ *of a piece of fudge. Okay. So here's the* $\frac{2}{8}$ *slab of fudge.*" [Researcher points to the piece of paper cut to represent $\frac{2}{8}$.] "*So here's my slab,*" [Researcher gestures to the slab], "*and it was cut, and this is* $\frac{2}{8}$ *of the whole, but he realized he actually wanted* $\frac{3}{8}$*, not just* $\frac{2}{8}$*. So, use this* $\frac{2}{8}$ *piece of fudge to create a* $\frac{3}{8}$ *piece. Okay?*" Dalton first takes the $\frac{2}{8}$ share and decides how to partition it to create a share.

Researcher:	Okay. And then Dalton, where's your $\frac{3}{8}$. [Dalton taps his fudge strip]. Okay. And why would it be there?
Dalton:	Well, so I would have to figure out $\frac{1}{8}$ [Dalton picks up the $\frac{2}{8}$ piece and taps it] the length of $\frac{1}{8}$, because I'm cutting at least $\frac{1}{8}$ over here [Dalton uses his hand to imitate a cutting motion on his fudge slab], but I need to figure out where to cut. [Dalton halves the $\frac{2}{8}$ share and cuts along the partitioned line to create two $\frac{2}{8}$ shares. He then iterates this three times along the larger fraction stip.]
Researcher:	Okay. So, where's your $\frac{3}{8}$ now?
Dalton:	Right here. [Dalton points at his fudge strip.]
Researcher:	Right here? Just that piece?
Dalton:	No, all of this is $\frac{3}{8}$. [Dalton gestures to three shares he created on his fudge strip.] That's just the line to stop.

Here, Dalton uses the halving and doubling he seemed to begin developing in Teaching Experiment Session 3 with both his whole number and fraction tasks. Differences that indicate changes to his schemes for whole number and fraction activity are his ability to anticipate how to halve and double when partitioning and iterating (cf. Tzur, 2007). For instance, when Dalton first engages in the halving partitioning and doubling iterating, he seems to do this in the moment and does not elicit this to make this strategy more sophisticated but seems to draw on this activity

implicitly. Moreover, he does not describe this halving and doubling activity as a strategy that would help him solve the task, but he seems to find himself using this when asked to reflect on his strategies. The activity not only develops and connects whole number and fraction activity but eventually allows Dalton insight into how he can solve complicated tasks more efficiently.

Relationships Between Angela's Whole Number and Fraction Understandings

Similar to Dalton, Angela also drew from halving and doubling activity when she solved whole number and fraction tasks. Interestingly, she uses this explicitly but often struggles to describe exact solutions, as she finds this activity alone to limit her capabilities. For instance, in Teaching Experiment Session 5, both students are given the task, "Show the card above (see Figure 1). Explain that there are 15 dots altogether, and that each row has five dots. How many rows are there? And how do you know?" Dalton first explains that he thinks there are five rows, each with five dots. Angela disagrees, explaining that having five rows "would pass" fifteen because "five and five is ten."

Angela:	And those are just two times. [Holds up two fingers in her right hand, pointer and middle fingers.]
Researcher:	Okay.
Angela:	And then, like you have to do it three more times. [Holds up three fingers on her left hand], and it'll be like twenty or twenty-one. It would be past fifteen.

Angela's doubling allows her to judge the reasonableness of Dalton's solution and provide a logical reasoning as to why his solution would not make sense. Limitations around this activity are Anegla's inability to ultimately answer the question posed to her. She could double five once but struggles to distribute a unit of five along her number sequence beyond ten, as she describes five and five making ten, but then is unable to explain the result of how ten and one more five can be composed. In fact, she may even be doubling again, considering "twenty or twenty-one" as a reasonable solution for five groups of five.

By Teaching Experiment Session 11, Angela begins distributing groups of five more multiplicatively, allowing her access to more efficient strategies when solving whole number tasks. For instance, the task posed to both students was, "*There are 4 teams in a school. Each team has 5 players. Joy said there are 35 players in all, because she skip-counted by 5 (Joy said, 5-10-15…" and kept going to 35). Is Joy correct? If not, how many teams did Joy count?"* Angela decides that Joy is not correct and explains that Joy is counting too many teams.

Angela:	So, he's trying to do six [holds up five fingers on her left hand and her pointer finger on her right hand to have six total], but it actually needs to be four. [Angela puts down fingers until she has four fingers left on her left hand]. So, five, ten, fifteen, twenty, [Points with her right pointer finger to her left pinky, ring, middle, and pointer finger] because I think it was twenty because there was four and was skipping by five's. [Angela gestures to her four fingers and does hand motions while talking].
Researcher:	Four what? So what do your fingers represent?
Angela:	There's four teams.

Here, Angela is coordinating groups of five beyond her original doubles activity, allowing her to now not only reason logically why Joy's solution does not make sense, but also to explain what the correct answer should be.

In the final handful of sessions, Angela is beginning to reason multiplicatively and engage in fraction tasks in relatively more sophisticated ways. For instance, in Teaching Experiment Session 14, both students are given the fraction task, "*At a fudge factory, the workers pour hot fudge into long rectangular trays and let it cool into slabs. Once the fudge has cooled, the workers slice the slab of fudge into an equal number of parts and put those pieces into display cases in the store. Carlos selected ⅜ of the slab of fudge. Alex saw Carlos's piece and said that it is three times more than what I want. What size piece of fudge does Alex want?*" Angela immediately multiplies three times eight and explains that the answer is "one-twenty-fourth".

Researcher:	Okay. Alright. So what was your reason for one-twenty-fourth? What do you think?
Angela:	I think one-twenty-fourth, because if you did eight times three would be twenty-four, and we kept the one, so it'll be one-twenty-fourth.
Researcher:	Oh, okay. Can you show me where that one-twenty-fourth looks like on here, like Dalton did for his? (Angela slides the one-eighth piece along the fudge strip three times). Okay, so the same, you're going to say the same size piece, but you're going to call that one-twenty-fourth.
Angela:	Yeah.

Here, Angela is using her multiplicative reasoning to solve this task and distributes a $\frac{1}{8}$ share across the paper strip three times, resulting in a $\frac{3}{8}$ size piece. However, she is using her multiplicative reasoning to also name this piece $\frac{1}{24}$, suggesting that she has not yet formalized her understanding of what $\frac{1}{8}$ three times can be represented as. Hence, we posit this understanding is participatory, meaning Angela does not understand structural relationships that she can anticipate in future activity.

By Teaching Experiment Session 16, Angela is given the task, "*At a fudge factory, the workers pour hot fudge into long rectangular trays and let it cool into slabs. Once the fudge has cooled, the workers slice the slab of fudge into an equal number of parts and put those pieces into display cases in the store. Carlos selected 5/8 of the slab of fudge. Alex saw Carlos's piece and said that it is five times more than what I want. What size piece of fudge does Alex want?*" In many ways, this task asks Angela to engage in the inverse of her activity when partitioning $\frac{5}{8}$ to conceptualize $\frac{1}{8}$ as five times smaller than $\frac{5}{8}$. After hearing the task, Angela talks aloud to conceptualize what the task is asking, stating, "Is it like they're trying to get 5 times smaller than 5 times?" and then, "So 5 times 5 is 25, but you don't times it because he wants less." Following these moments of her conceptualizing what the task is asking, Angela begins developing a strategy where she decides she needs to create the whole before "minusing". As Angela is partitioning the $\frac{5}{8}$ to create $\frac{1}{8}$ pieces, she reverts to whole number counting (one, two, three, four, five) and iterating to determine the size of the $\frac{1}{8}$ pieces in the $\frac{5}{8}$ share. In fact, in the end, she struggles to understand the new relationship between the parts and whole. This suggests that her ability to multiplicatively distribute fractional units across the whole and the composite fractional unit was limited based on her ability to inversely engage with multiplicative relationships.

Conclusion

Both students developed fractional activity from their whole-number activity; however, Angela appeared to engage in greater reorganization than Dalton, as reflected in her coordination of unit structures. In contrast, Dalton often developed fractional knowledge by mapping his

whole-number activity directly onto fractional situations. At times, Dalton also extended his whole-number activity through his fractional activity, suggesting that the two sets of relationships developed in tandem.

In consideration of both students' iterating and partitioning development across their whole number and fraction strategies, it seemed that both students began with and often revisited a trial-and-error type of iterating and partitioning. This allowed them to construct and reconstruct part-whole relationships while refining their reasoning to more robustly understand inverse part-whole relationships between their whole number and fraction understandings. Also, both students developed access to particularly challenging whole-number and fraction relationships through halving and/or doubling. This initially emerged as part of their strategy development before becoming an intentional part of their activity for accessing early forms of multiplicative relationships and fraction relationships. Finally, Angela began developing multiplicative connections between her whole-number and fraction understandings. As she developed these relationships, she struggled with the inverse reasoning required to transition from whole number multiplicative reasoning to fraction multiplicative reasoning. Exploring these forms of iterating and partitioning with whole-number and fraction tasks can better inform the literature as to why and when it is beneficial to leverage the iterating and partitioning strategies students with ISM demonstrate.

Students with mature number sense understand numbers and operations, use reasoning to notice patterns, and flexibly select the most effective and efficient problem-solving strategies (McIntosh et al., 1997; Yang, 2005). Despite being highlighted in national standards and policy documents (CCSS, 2010; NCTM, 2000), the association between elementary and middle school students' number sense and other important outcomes in mathematics education is not well specified. To begin to address this, we analyzed 3rd–8th grade students' (N = 1305) scores on a measure of mature number sense and their fluency with single-digit multiplication facts. We found that students' multiplication fact fluency was significantly associated with their mature number sense, controlling for school and individual demographic factors, but the strength of this association differed significantly by students' grade-level.

Keywords: Number Concepts and Operations, Cognition, Elementary School Education, Middle School Education

One goal of mathematics education reforms in the United States is to help students develop number sense, which involves making sense of numbers and operations, using flexible reasoning to notice patterns, and selecting the most effective and efficient problem-solving strategies (CCSS, 2010; National Council of Teachers of Mathematics [NCTM], 1989, 2000; National Research Council [NRC], 2001). For example, students exhibiting number sense understand $8 \times 6 = 48$ as a logical extension of $8 \times 5 = 40$ by representing 48 as 40 with an additional group of 8. Rather than seeing them as disparate facts, students with number sense have a connected understanding of numbers and operations. Despite being a central goal in mathematics education, there is limited evidence on the typical progression of students' number sense across elementary and middle school, and it is unclear if there is an association between students' number sense and other outcomes in mathematics education, such as knowledge of single-digit arithmetic. In this study, we aimed to begin addressing these questions on how 3rd–8th-grade students' number sense relates to their fluency with single-digit multiplication facts and whether the strength of this association differs based on students' grade or number sense component.

Background and Theoretical Framework

In the late 1980s, government-commissioned reports (NRC, 1989) and national curriculum frameworks (e.g., NCTM, 1989) highlighted "number sense" as a core objective of K-12 mathematics education. However, there has been a significant divergence in how researchers

operationalize ‘number sense’ and examine it with students (Berch, 2005). This paper draws upon Whitacre et al.’s (2020) use of the adjective “mature” to differentiate the construct studied here from both approximate (e.g., Dehaene, 2001) and early number sense (Jordan et al., 2022). We define *mature number sense* in line with McIntosh and colleagues (1992) as the ability to use an understanding of both numbers and operations to flexibly and efficiently solve problems. Importantly, this is not to imply that maturity in number sense naturally develops with age, that the number sense of 3rd graders is *fully mature*, or that our construct of interest is different from prior number sense work in mathematics education (e.g., Markovits & Sowder, 1994). Rather, it is solely to avoid a case of polysemy in the literature.

Perhaps to facilitate operationalization in empirical research, mature number sense has often been subdivided into components (NCTM, 1989; Reys et al., 1999; Yang & Lin, 2015). Building from this prior work and in consultation with teacher educators, researchers, and mathematics teachers, we specified a four-component framework of mature number sense (Kirkland, Cheng, et al., 2024; Kirkland et al., 2025) with mature number sense as the overarching latent construct. Student response data from our assessment reflect this framework. A bifactor model with each component as a specific factor best fit the response data over theoretically related models.

1. Understanding fundamental number concepts and number magnitude: Students demonstrating strong mature number sense understand fractions, decimals, whole numbers, and their corresponding magnitudes. Students efficiently estimate results using concepts such as unit fractions and the value of digits within a number.
2. Using multiple representations of a number: Students demonstrating strong mature number sense are able to translate among multiple representations of rational numbers efficiently and flexibly to solve problems. Students use this understanding to convert between rational numbers represented pictorially, as fractions, or as decimals, to make sense of numerical situations.
3. Understanding the effect of operations on numbers: Students demonstrating strong mature number sense recognize how the four core operations affect whole numbers as well as fractions and decimals. They understand that patterns observed in operations with whole numbers may not hold true for fractions and decimals between 0 and 1. Students use this understanding to efficiently estimate computational results and ensure the results make sense given the relationship between operations and rational numbers.
4. Understanding mathematical equivalence: Students demonstrating strong mature number sense understand the equal sign as a relational symbol, reflecting that the two sides of an equation are equal and interchangeable. Students who understand equivalence recognize patterns across the equal sign and use this relational thinking to flexibly and efficiently solve problems (c.f., Jacobs et al., 2007). Students use the properties of the four core operations, such as commutativity and distributivity, to generate equivalent expressions.

Mathematics educators care about improving students’ mature number sense, in part, because they argue it lays a foundation for better learning of more advanced mathematics (Boaler, 2019; Yang & Wu, 2010). However, there is limited evidence that mature number sense is positively correlated with other constructs (summarized in Kirkland, Guang, et al., 2024). In this study, we focused on a key component of upper elementary and middle school students’ mathematical proficiency: their fluency with single-digit multiplication facts.

Rationale for Current Study

Multiplication is traditionally introduced to US students in 3rd grade, with the goal that students know all products of single-digit factors from memory by the end of that year (CCSS, 2010). This retrieval of facts from memory is often referred to as *multiplication fluency* or *automaticity.* As a subset of students' broader arithmetic fluency (i.e., McNeil et al., 2025), we define *multiplication fluency* as the efficient and accurate mental retrieval (i.e., correct response in ~3 seconds) of products of single-digit numbers. The importance of students' multiplication fluency has been debated recently across special education and mathematics education (Codding et al., 2023; NCTM, 2023). Amidst these debates over how best to *teach* arithmetic facts, there is consistent evidence that students' *knowledge* of single-digit multiplication facts is a significant predictor of their future mathematics learning. Nelson et al. (2016) found that students' fluency with multiplication predicted later math success, even extending beyond the grade levels where these facts are formally taught. Hansen et al. (2015) found 6th grade students' multiplication fluency significantly predicted their proficiency with fraction computation across the four arithmetic operations. Additionally, McGlaughlin et al. (2005) found that for college students with identified mathematics disabilities, fact fluency performance significantly predicted their success in a college algebra course. Thus, supporting students in their development of multiplication fluency is a crucial outcome in K-8 mathematics (McNeil et al., 2025).

The association between students' mature number sense and their multiplication fluency is inconclusive. Recently, we found that 3rd–5th grade school students' multiplication fact fluency was strongly positively correlated ($r = 0.66$) with their mature number sense (Kirkland et al., 2023). However, the within-grade-level sample sizes ($N = 47, 53, 53$ respectively) limit the generalizability of these findings across grade levels, and there are significant developmental differences in upper elementary. After being introduced to single-digit multiplication in 3rd grade, students are expected to apply this knowledge to more complex operations in 4th and 5th grade, including multidigit multiplication and division (e.g., long division and partial quotients), generating equivalent fractions, finding a common denominator for fraction comparison, factoring, and place value understanding (CCSS, 2010). Third grade is also when students are first introduced to division and fractions as numbers. Therefore, we aimed to collect a larger sample in this study to more fully explore whether the association between students' mature number sense and their multiplication fluency changes across these grade levels. In addition, the association between middle school students' multiplication fluency and mature number sense has yet to be examined in the literature. As noted above, prior work has found advanced fluency with multiplication facts to be predictive of later math proficiency, beyond the grade levels when the facts are formally taught (e.g., Nelson et al., 2016). Therefore, we aim to test how mature number sense relates to students' fluency with multiplication at both the upper elementary level, when students are just learning their multiplication facts, and in middle school, when students should be fluently using those facts to solve more advanced mathematical problems.

To start to address this gap in the literature, we aimed to study if the correlation between mature number sense and multiplication fluency was moderated by students' grade level, controlling for both individual and school level demographic factors. Our research questions were as follows: (1) How does 3rd–8th-grade students' mature number sense relate to their fluency with multiplication? and (2) Does the strength of this association differ based on students' grade level or the components of mature number sense?

Methods

Participants

In August 2025, our research team sent invitations to teachers and school leaders in our local and national network of educators to participate in an ongoing longitudinal study. For the primary analysis of interest in that longitudinal study, our power analysis indicated that a minimum of $N = 125$ for each grade level or a total sample of $N = 750$ students was necessary. Thirty-five teachers from eleven different schools across the United States agreed to have their math classrooms participate. For the timepoint 1 data presented here, 1305 students from these classrooms participated (45% self-identified as female; 44% self-identified as White, 11% Hispanic or Latino, 9% Multiracial, 8% Black, 2% Asian, and 26% as unlisted or unsure).

Procedure and Measures

Teachers administered the assessments described below in the context of their usual mathematics classrooms. Students completed the measures at a time determined by the teacher via a Qualtrics survey on school-provided devices (e.g., Chromebooks) in a set order: assessment of mature number sense, then multiplication fluency. All assessments for timepoint 1 were completed between mid-August and the first week of October.

Brief assessment of mature number sense (Kirkland et al., 2025). This is an electronic, 24-item multiple-choice test of students' mature number sense, aligned with our theoretical framework. Items are designed specially to assess students' number sense rather than general mathematics achievement. Each item has a time limit of 60 seconds, and students are not allowed to use paper or pencil to discourage using algorithms. Two different assessments were used: one for elementary school (3rd–5th grade) and another for middle school (6th–8th grade). There were eight common linking items across the two forms, allowing for a vertically scaled score (see Figure 1). Scores were calculated as the total number correct (sum score) as well as a latent trait estimate of students' number sense using an expected a-posteriori (EAP) method with a multivariate normal prior distribution (Chalmers, 2012) with a mean of 0. Using the mean and sigma linking method (Embretson & Reise, 2000) the latent trait estimates for 3rd–5th grade students' mature number sense are transformed onto a common scale with 6th–8th grade students (i.e., a score of 0 reflects performance at the mean level for middle school students). This transformed latent trait estimate score is used in this study to allow for comparisons across the two forms. The validation analyses (Kirkland, Cheng, et al., 2024; Kirkland et al., 2025) provide strong validity evidence for the intended use of student scores supported by expert reviews, factor analyses, student retrospective think-aloud protocols, and item response theory analyses.

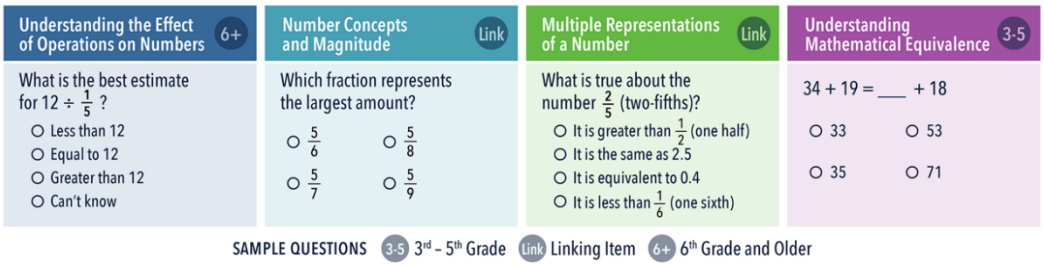

Figure 1: Sample Questions from Brief Assessment of Mature Number Sense

Multiplication fact task (Burns et al., 2015; Nelson et al., 2013). Participants were given one minute to complete this measure, which includes all combinations of single-digit

multiplication facts using the digits 1–9. Students received 1 point for each correct response, with possible scores ranging from 0–81 (observed range of 0–39 in this study). The order of the facts was randomly predetermined and then kept standard for all participants.

Data Analyses

To address Research Question 1 on how students' mature number sense relates to their multiplication fluency, we first calculated the overall Pearson correlation between student scores on the two measures. We then ran a series of regression models, with students' mature number sense as the outcome variable, testing if students' multiplication fluency is significantly predictive of their number sense, controlling for demographic factors. The first model was a simple linear regression with multiplication fluency as the only predictor. The second model included all demographic variables (gender, race, grade, school) and was a Hierarchical Linear Model (HLM) or mixed-effects model to best model the naturally occurring nesting structure for the participants within the 11 different schools (Raudenbush & Bryk, 2002). For the demographic variables, the largest group was coded as reference, except in the case of grade-level. For grade-level, 3rd grade was coded as the reference to examine changes developmentally.

To address Research Question 2 on whether the association between the two target constructs differs by grade level and component of mature number sense, we first calculated the zero-order correlations within each individual grade level and within the two developmental levels (elementary vs. middle school). To test if the association is significantly different by grade-level, we tested for a significant categorical moderation effect of grade level on fluency. We then probed the moderation effect and tested the pairwise comparisons of each grade level's slope, adjusted for multiple comparisons using Tukey's HSD (Tukey, 1953).

To examine if the association between multiplication fluency and mature number sense differs by component, we first calculated sum scores for each component (NCM: Number Concepts and Magnitude, MR: Multiple Representations, EO: Effect of Operations, EQ: Equivalence). We could not use the latent transformed score for this analysis as the latent subscores have not been shown to be reliable given the small number of items per component. We calculated the zero-order correlations between component subscores and multiplication fluency for both elementary and middle school. We then ran a linear regression model with multiplication fluency as the outcome to allow for all four components to be predictors. From this analysis, we compared each regressor's semi-partial correlation coefficient to analyze each component's importance to multiplication fluency (Darlington & Hayes, 2016).

Results

We first begin with overall student performance, summarized by grade level in Table 1. Students solved on average 11.65 (49%*)* items correctly on the brief assessment of mature number sense (SD = 5.21). On their respective forms, upper elementary students solved fewer correctly (M = 9.82, SD = 4.6) compared to middle school students (M = 13.04, SD = 5.22). Overall, students' mean transformed latent estimate of their mature number sense was –1.22 (SD = 1.65). On average, students solved 12.55 (SD = 8.08) single-digit multiplication problems correctly. Once again, upper elementary students solved fewer correctly (M = 7.19, SD = 6.11) than middle school students (M = 16.63, SD = 6.93).

To begin to address Research Question 1, we calculated the zero-order correlations between the two constructs in the whole sample. As predicted, students' mature number sense and multiplication fluency were strongly positively associated (r = 0.73), and this was significant, ($t(1303) = 38.12$, $p < .001$). We then conducted the base linear regression to further explore the

association. An increase of one correct multiplication fact is associated with a 0.15-point predicted increase ($b = 0.15$, $p < .001$) in a student's mature number sense latent trait estimate. This significant association holds in the full mixed-effects model with all relevant demographics included, ($b = 0.06$, $p < .001$). In the whole 3rd–8th grade sample, students' multiplication fluency and mature number sense are significantly related.

Table 1: Correlation Between Number Sense and Multiplication Fluency by Grade

Grade Level	*N*	Mature Number Sense		Multiplication Fluency		*r*
		M	*SD*	*M*	*SD*	
3rd Grade	159	–3.38	0.78	1.92	2.58	0.49
4th Grade	222	–2.78	1.07	6.61	4.35	0.34
5th Grade	183	–1.89	1.38	12.47	5.82	0.42
6th Grade	345	–0.22	0.87	15.96	6.24	0.51
7th Grade	165	0.06	0.92	18.13	6.59	0.49
8th Grade	231	–0.13	0.90	16.57	7.95	0.49
Overall	1305	–1.22	1.65	12.55	8.08	0.73

To address Research Question 2, we then examined how this association may differ by grade level. The grade-level specific correlations are summarized in Table 1. Descriptively, we see the lowest correlation among 4th-grade students ($r = 0.34$) and the highest with 6th grade students ($r = 0.51$). To test if any grade-level differences are significant, we ran a mixed-effects model with students' mature number sense as the outcome of interest, their multiplication fluency, grade level, and school as predictors, and a grade level by multiplication fluency interaction term. Each grade level's (4th–8th) interaction term with multiplication fluency was significant (model summarized in Table 2). The full model with the interaction term fit significantly better than the base model, $\chi(5) = 29.2, p < .001$, suggesting that the strength of the association between students' multiplication fluency and their mature number sense is moderated by grade level. That is, there are grade-level differences in the strength of the association between the two constructs. To probe this interaction, we calculated and compared the slope term for students' multiplication fluency at each grade level (see Figure 2). We tested all of the pairwise comparisons for grade-level slopes (e.g., 3rd vs. 4th, etc.) and corrected for multiple comparisons using Tukey's HSD. In this analysis, the slope for 3rd grade students' fluency was significantly more positive than 4th grade ($p < .05$), 6th grade ($p < .01$), 7th grade ($p < .01$), and 8th grade ($p < .001$). For 5th grade students, the slope of their fluency was significantly more positive than 6th ($p < .05$) and 8th ($p < .01$) grade students. No other pairwise comparisons were significant.

Figure 2: Multiplication Fluency and Mature Number Sense by Grade

Table 2: Summary of Regression Model Predicting MNS with Grade-level Interactions

Variable	*B*	*SE*	*t*	*p*
(Intercept)	–4.00	0.18	–22.60	<0.001
Multiplication Fluency	0.15	0.02	6.26	<0.001
4th Grade	0.55	0.13	4.25	<0.001
5th Grade	0.86	0.16	5.31	<0.001
6th Grade	2.83	0.15	18.65	<0.001
7th Grade	2.78	0.21	13.39	<0.001
8th Grade	3.02	0.16	18.87	<0.001
Fluency * 4th Grade	–0.08	0.03	–2.87	<0.01
Fluency * 5th Grade	–0.06	0.03	–2.06	0.03
Fluency * 6th Grade	–0.10	0.03	–3.78	<0.001
Fluency * 7th Grade	–0.09	0.03	–3.56	<0.001
Fluency * 8th Grade	–0.10	0.03	–4.11	<0.001

To analyze if the association observed above differs by the component of mature number sense, we calculated the zero-order correlations between component subscores and students' multiplication fluency. Since the items across components differ in the two forms, we analyze elementary school students first and then middle school students. For elementary students, the descriptively highest correlation was with multiple representations ($r = 0.51$), followed by number concepts and magnitude ($r = 0.49$), equivalence ($r = 0.39$), and effect of operations ($r = 0.34$). In middle school, a different pattern was observed. The correlations were all more similar, with equivalence ($r = 0.46$) the descriptively largest, followed by number concepts and magnitude ($r = 0.45$), multiple representations ($r = 0.44$), and effect of operations ($r = 0.41$).

To probe the relative strength of each component's association with multiplication fluency, we ran linear regression models for each developmental level. For elementary students, all four components were significant predictors in the model. To compare them directly, we calculated the semi-partial correlation for each component with multiplication fluency. Similar to above, we found that, for elementary students, multiple representations ($sr = 0.23$) and number concepts and magnitude ($sr = 0.20$) were the two components most strongly linked with multiplication fluency. Equivalence ($sr = 0.11$) and effect of operations ($sr = 0.08$) were lower. With middle school students, all four components were significant predictors, but equivalence ($sr = 0.17$) was the strongest related of the four. Multiple representations ($sr = 0.12$) and number concepts and

magnitude ($sr = 0.11$) were next, with effect of operations ($sr = 0.07$) the lowest. Overall, we see that the components differ in strength of association with multiplication fluency between upper elementary and middle school students, with multiple representations the strongest association in upper elementary and equivalence the strongest for middle school.

Discussion

From the evidence presented here, students' mature number sense and multiplication fluency are strongly positively associated across upper elementary and middle school ($r = 0.73$ in the whole sample). This strong positive association held when controlling for both school-level and individual-level demographic factors. Within grade levels, however, the strength of this association differed significantly. Students' multiplication fluency and mature number sense were most positively associated in 3rd grade and then in 5th grade. In terms of the components of mature number sense, surprisingly, students' understanding of the effect of operations on numbers was the least positively related to their multiplication fluency. For elementary students, their use of multiple representations of numbers correlated most strongly with their fluency. For middle school students, it was their understanding of mathematical equivalence. Together, this all suggests that there is a strongly positive association between 3rd–8th grade students' mature number sense and their knowledge of single-digit multiplication facts, but there are developmental and component-specific differences in the strength of that association.

Across 3rd–8th grade, the patterns observed with 3rd grade students' mature number sense and multiplication fluency were distinct from those of other grades. Perhaps not surprisingly, 3rd grade students had the lowest level of mature number sense ($M = -3.38$) and multiplication fact fluency ($M = 1.92$ correct). As discussed above, 3rd grade is a unique time in students' mathematical development. Students are first introduced to multiplication, division, and fractions as numbers. It may be that students need the full 3rd grade year to acquire new mathematical knowledge in these domains, consolidate this knowledge, and connect it with their initial number sense understanding with whole numbers. The results presented here reflect start-of-the-year knowledge, so 3rd grade students may not yet have begun practice with single-digit multiplication. Despite this, the strength of the association between the two constructs was strongest in 3rd grade. We interpret this as reflective of how few 3rd grade students displayed multiplication fact knowledge. Of the 159 students in 3rd grade, only 20 (13%) correctly answered more than three multiplication facts. For this group, their mean number sense was –2.55, almost a full standard deviation above the 3rd grade mean. Their early knowledge of multiplication as an operation may have allowed them to access more items on the number sense assessment, leading to stronger performance. Further analysis of this association longitudinally across the rest of 3rd grade will shed light on the observed findings in this study.

Among the four components of mature number sense, students' understanding of the effect of operations on numbers had the weakest association with their multiplication fluency. This was surprising to us given many effects of operations items directly assess multiplication (e.g., "What is the best estimate for $26 \times \frac{3}{4}$?", "What is true about 18×12?"). However, many of these items include operations with fractions and decimals, rather than solely whole numbers. It may be that students with higher multiplication fluency have had more exposure to repeated traditional arithmetic practice and are, therefore, more susceptible to whole number bias. The effect of operations items directly assess several common "rules that expire" from elementary (e.g., Karp et al., 2014), such as "multiplication makes a number bigger." The evidence here suggests that,

while positively associated, strong retrieval of single-digit multiplication facts does not guarantee an understanding of multiplying and dividing rational numbers (e.g., Siegler & Pyke, 2013).

Overall, we have evidence here on the association between 3rd–8th grade students' mature number sense and their knowledge of single-digit multiplication facts. We see that the strength of this association differs by grade level and by mature number sense component. Though evidence from only one timepoint with online measures, this is an important first step in more fully understanding how these two important constructs in mathematics education develop in upper elementary and middle school. Future work can extend this analysis longitudinally to map their natural progression over the course of a school year. By continuing to characterize mature number sense's natural progression, researchers can better identify the pivotal developmental windows for supporting student sense-making with numbers and operations.

Current research on decimal multiplication suggests that students rely on memorized rules to apply the Decimal Placement Rule, with little to no scholarship examining the role of their multiplicative reasoning on such tasks. This study explored students' engagement with decimal multiplication tasks and how their actions corresponded with their multiplicative reasoning. Eye-tracking enabled clinical interviews were conducted with 28 fifth and sixth grade students. Findings indicate students' multiplicative reasoning corresponds to both their application of the Decimal Placement Rule, and their engagement with place value in decimal multiplication.

Keywords: Elementary School Education; Number Concepts and Operations

Multidigit multiplication is an understudied topic (Fuson, 2003; Hickendorff et al., 2019), with multiplication of decimals receiving even less attention in the research literature. Current scholarship on multidigit multiplication of whole numbers suggests that students understanding of partial products, which involves a place value based application of the Distributive Property, is a conceptually difficult concept for students (Gill et al., 2025; Hickendorff et al., 2019; Izsàk, 2005). Interestingly, others have observed that place value is an important factor in students' decimal multiplication as well (Larsson et al., 2017; Lortie-Forgues & Siegler, 2017), but we have been unable to identify literature examining the relationship between these. Those who have studied children's decimal multiplication have found that students often follow rotely learned procedures, with many errors occurring when decimal problems aren't presented in recognized formats (Hiebert & Wearne, 1985; Larsson et al., 2017). Even when students demonstrate strong whole number multiplicative reasoning, they have difficulty with decimal multiplication (Larsson et al., 2017). What is less understood is how students' varying multiplicative reasoning with whole numbers associates with their decimal multiplication, and how such multiplicative reasoning is associated with students' reasoning about decimal multiplication. Given the role of place value in both whole number and decimal multiplication, there is a need to understand how students' reasoning with each intersects. Thus, the purpose of this study was to explore how fifth and sixth grade students, with different levels of multiplicative reasoning, reasoned through decimal multiplication tasks.

Theoretical Perspective

Multiplicative Reasoning & Whole Number Multiplication

Multiplicative reasoning emerges when individuals can conceptualize a number as being both one unit and an iterated composite of multiple units (Hackenberg, 2010; Kosko, 2019; Nunes et al., 2010; Tzur et al., 2021). We discuss this unit coordination through Scheme Theory with particular focus on Hackenberg's (2010) description of three multiplicative concepts. The first multiplicative concept (MC1) describes children's ability to anticipate one level of units and construct the second level. A child at MC1 may solve 6×6 by iterating 6 six times until reaching

36. Such children may also use doubling or repeated addition as they learn to coordinate units in more nuanced ways (Ambrose et al., 2003; Hickendorff et al., 2019; Lampert, 1986). In solving 16×6, the same student may iterate 16 six times (Gill et al., 2025). At the second multiplicative concept (MC2), a child anticipates two levels of units and constructs the third level in activity. Such children may solve 16×6 by partitioning 16 into 10 and 6 and multiplying each by 6; what we refer to as meaningful use of two partial products (Gill et al., 2025; Izsàk, 2005). Students learn to work with partial products by integrating their understanding of 10s multiples with the distributive property to break apart a two-digit number and multiply it by a single-digit number (Ambrose et al., 2003; Flores et al., 2020; Izsàk, 2005).

At the third multiplicative concept (MC3), children can anticipate three levels of units (Hackenberg, 2010). It is at this point that a child can meaningfully use four or more partial products (Gill et al., 2025). Many conjecture that by using four partial products, a child can generalize to partial products with more place-value components (Flores et al., 2020; Hickendorff et al., 2019). A child at MC3 may solve 16×56 by coordinating four separate expressions (10×50 + 10×6 + 6×50 + 6×6). Key in distinguishing between these levels of multiplicative reasoning is that children can be at a lower level and solve a more complicated task using a rotely learned procedure. Thus, they may be able to fluently use an algorithm rotely, but may not be able to explain the place-value meaning of certain operations or relate the operations to a visual or concrete representation (Kosko, 2024; Gill et al., 2025).

Decimal Multiplication
