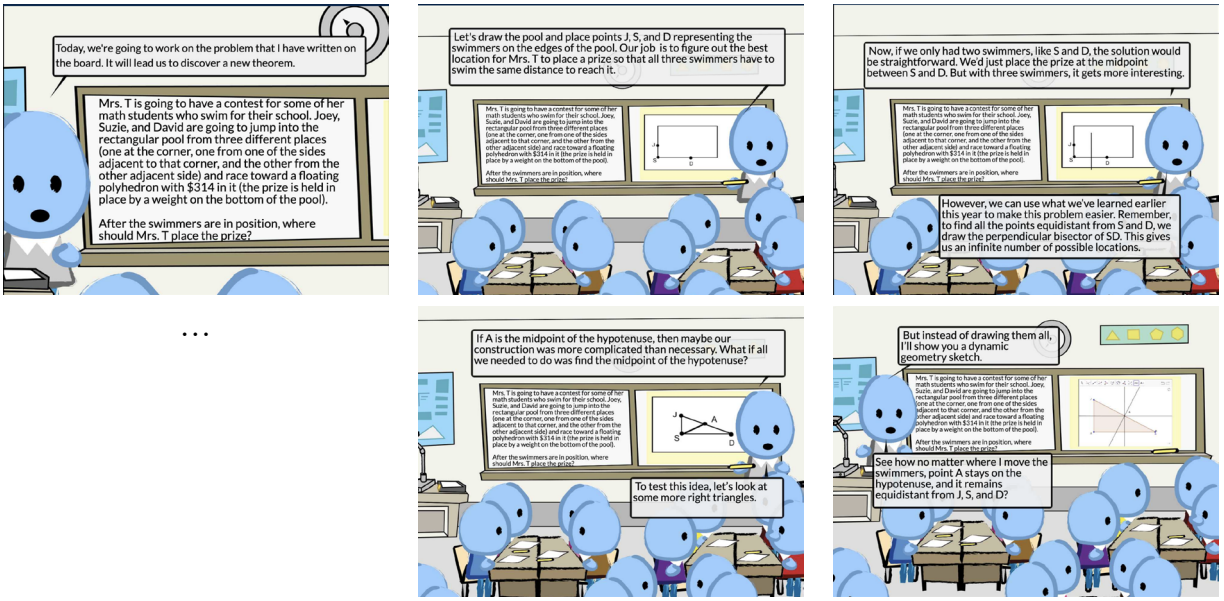
In Story*Circles*, teachers start by reviewing a lesson representation built around a novel problem. The representations were deliberately constructed to deviate from some expectations common in reform-based, student-centered instruction as articulated in U.S. professional teaching standards (NCTM, 1991). Specifically, the lessons were designed to follow the Worthwhile Tasks standard, which calls for introducing new content through problems, while departing from the Discourse Standard (NCTM, 1991), which calls for teachers to orchestrate classroom discourse in ways that elicit and build on student thinking (Lampert, 2001). While the lesson started with a problem whose work would usher in new knowledge, the teacher in each lesson representation solved the problem with minimal student participation, providing direct exposition rather than facilitating student exploration and discourse (see Figure 1).



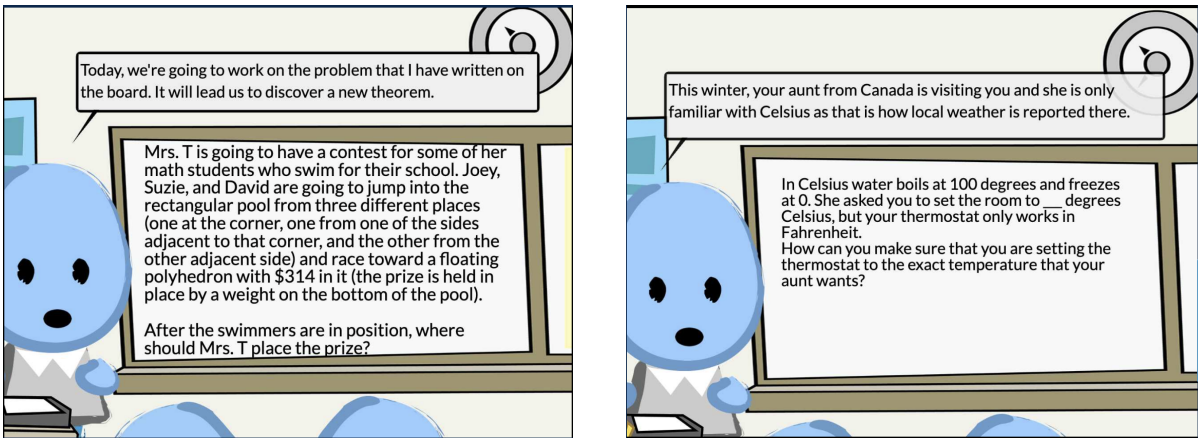


Figure 1: Example Sequence from the Geometry Lesson

This design intentionally presented instruction that deviates from expectations teachers might hold for exemplary professional development in order to acquaint teachers with the content of the lesson and elicit the desire to involve more student participation–none of which goals were conveyed to them directly. Prior to each synchronous session, participants reviewed the lesson representation asynchronously and posted comments using the *Anotemos* software embedded in Canvas. Before the module was presented, participants were informed only that the lesson would utilize problem-based instruction within a teacher-centered approach. Teachers placed written comments directly on the storyboard at moments of their own choosing. The activity was entirely open-ended, meaning that teachers were not paused at predetermined moments or asked to evaluate specific pedagogical moves. While two optional, pre-written sentence starters ("Students might be thinking…" and "The teacher should… because…") were available in the interface to assist participants in framing their thoughts, the participants could use these sentence starters at any moment of the lesson they wanted to comment on.

Participants included 64 secondary mathematics teachers from the United States (n = 36) and four non-U.S. contexts (n = 28). Of the 310 annotations in the data set, 107 were excluded

because they did not reflect teachers' spontaneous attention to the lesson. These included responses to required navigation prompts (e.g., "What key mathematical ideas do you notice in this frame?" and "Before continuing, take a moment to try the problem for yourself"); empty pin placements with no written comment; on-screen drawings; and irrelevant entries (e.g., "Hi, this is a test"). The final analytic sample consisted of 201 written annotations produced in response to two lesson representations (one in Algebra and one in Geometry), which started with novel problems (converting temperatures across two scales and placing a prize inside a pool) that ushered respective new ideas (the equation of the Line through Two Points and the Midpoint of the Hypotenuse Theorem) (see Figure 2). These annotations served as the primary unit of analysis for examining patterns of teachers' reactions to the lesson.

(a) (b)

Figure 2: The Problem Presented in (a) the Geometry Lesson and (b) the Algebra Lesson

Data Analysis

The coding scheme was developed abductively, moving between the design intentions of the lesson and the patterns we explored in teachers' annotations. We began from the structural design intent of the lesson representations: (1) Lack of student participation, (2) Teacher showing how the problem leads to the lesson goal, (3) Addressing common errors previously observed in the context of these problems. Then, rather than treating these design intentions as fixed codes, the research team went through all the annotations and traced how each appeared—how teachers attended to, commented on, or reacted to these features. This tracing did two things. It surfaced three pedagogical features aligned with the design intentions—(1) Active Student Engagement, (2) Teacher Facilitation and Eliciting Reasoning, and (3) Addressing Student Ideas and Misconceptions—and it revealed a fourth that the design had not anticipated: many teachers, particularly those in non-U.S. contexts, attended closely to the qualities of the problem itself. We therefore added (4) Problem Approachability and Quality, grounded in the data. The final coding scheme was thus settled only after this back-and-forth between design intention and data, rather than being imposed in advance or read off the annotations alone.

For each pedagogical feature, we specified the design characteristic integrated into the lessons and developed indicators for recognizing when teachers' comments showed attention to that feature (see Table 1). Annotations that addressed multiple features received multiple codes. Features were coded as Yes/No, where "Yes" indicated that a teacher's comment attended to the feature—whether by critiquing its absence or by approving of the teacher's choice—and "No"

indicated that the comment did not address the feature. This distinction separates whether teachers attended to a feature (captured by the Yes/No code) from how they evaluated it (examined in the qualitative analysis). We compared the proportions of "Yes" codes for each feature between groups using a chi-square test. Alongside this quantitative comparison, we analyzed the "Yes" annotations qualitatively to characterize how each group attended to and evaluated each feature. We also attended to patterns of "No" codes—that is, features a group did not comment on—since the absence of attention to a feature is itself informative about what each group treated as worth remarking upon.

Table 1: Coding Scheme for Identifying Noted Pedagogical Features

Pedagogical Feature	Departure from reform standard (NCTM, 1991; Lampert, 2001)	Example "Yes" Indicators	Example
Active Student Engagement	Teacher solves the problem without involving students	- Comments that "teacher is doing all the work" - Statements about students not having opportunities to work on problems	*"Instead of simply providing information about Fahrenheit; the teacher can engage students by asking about their prior knowledge. This approach encourages active participation and allows students to connect new concepts with what they already know."*
Teacher Facilitation & Eliciting Reasoning	Teacher shows all reasoning steps without student input	- Suggestions to elicit student ideas or thinking - Comments about need for questioning techniques - Proposals to have students explain their reasoning	*"Instead of directly defining a proportional relationship; students can analyze the graph's data points and make connections to concepts like the y-intercept; slope; and the corresponding equation."*
Addressing Student Ideas & Misconceptions	No student contributions; misconceptions are pre-stated by the teacher	- Comments about needing to hear student thinking - Suggestions to collect student ideas or solutions	*"Teacher is trying to break down the problem here… give students to come up with various possible points and then progress to the idea of perpendicular bisector and equidistant points*."
Problem Approachability & Quality	The problem is unfamiliar and conceptually generative	- Comments about problem difficulty or complexity	"*Initially the language of the question seems a bit vague- whether the points*

	are on other 2 corners or somewhere on the sides; and if on the adjacent sides; are they given or they have to be chosen?"

Findings

Analysis of 201 annotations (71 from U.S.-based teachers, 130 from non-U.S. teachers) revealed differences in how teachers from different national contexts attended to instructional features within the lessons. While both U.S. and non-U.S.-based groups of teachers evaluated each of the lessons, what features they chose to comment on—and how they evaluated each feature—differed in ways that may suggest different underlying assumptions about mathematics instruction. The analysis aggregates responses across lessons to focus on comparing them according to the national context where the participants came from.

Heightened Attention to Student Thinking

The most significant statistical difference appeared in the recognition of Addressing Student Ideas and Misconceptions ($p = 0.039$). U.S. teachers attended to this feature at a significantly higher rate (12.7%) than non-U.S. teachers (3.8%), with an odds ratio of 3.63, indicating U.S. teachers were approximately 3.6 times more likely to notice that student thinking was not addressed or elicited by the teacher. For these teachers, the lesson appeared inconsistent with what they expected from PD materials in that it fails to represent "exemplary" practice, as reflected in the comments such as: "*The teacher should… allow students to try this because… error analysis is a great way to assess conclusions made without evidence*." These annotations reflect an expectation—consistent with reform-based teaching standards (NCTM, 1991)—that student thinking should emerge, become visible, and drive instructional decisions. However, the lower rate of recognition among non-U.S. teachers does not indicate they failed to notice the lack of student participation but rather suggests different assumptions about when and how student thinking should surface in instruction.

Divergent Interpretations of Teacher-Centered Instruction

While both groups recognized features with teacher facilitation at a similar frequency, their qualitative evaluations revealed a divergence. When the lesson showed the teacher demonstrating solution steps with minimal student input, U.S. teachers predominantly responded to this as inconsistent with their facilitation expectations. Their annotations critiqued the teacher's "telling" approach (e.g., "*The teacher should ask what they noticed about the relationship instead of giving them the answer*"), explicitly noting that students were not given opportunities to construct their own understanding. This may suggest that these teachers read the teacher-centered approach as inconsistent with reform-based expectations for discourse-rich instruction. In contrast, a substantial number of non-U.S. teachers' annotations actively appreciated these same instructional moves. These teachers valued the teacher's guiding questions and explanations as effective pedagogical support (e.g., "*Question by teacher is good approach; where students start thinking in all possible ways*," "*Teacher gave a good clue to the students*"). Rather than viewing the teacher's guidance as problematic, these annotations framed the teacher's moves as helpful scaffolding rather than as a failure to elicit student thinking.

A parallel pattern emerged in *Active Student Engagement***,** with the groups recognizing features at a similar frequency. U.S. teachers who attended to this feature tended to frame the lack of student participation as a problem to be corrected, calling for students to do the mathematical work themselves rather than watch the teacher do it (e.g., "*Are the students*

discussing this; or is the teacher telling them?"). Non-U.S. teachers more often folded student involvement into appreciation of the teacher's moves, valuing opportunities for students to draw or explore while still crediting the teacher's guidance (e.g., "*Teacher can ask children to draw the figure themselves*"). Thus, even where the two groups noticed the same feature at similar rates, what they took the absence of student engagement to mean—a departure to be fixed versus a reasonable instructional choice to be supplemented—reflected the same divergence seen in their reading of teacher facilitation

Foregrounding the Worthwhile Task

While both groups remarked upon Problem Approachability at similar rates (8.5% vs. 11.5%), their annotations revealed different expectation priorities. Non-U.S. teachers more frequently attended to the mathematical and structural qualities of the problem itself, commenting on its "novel nature," "explorative quality," or conceptual richness (e.g., "*This problem provides opportunities for spatial reasoning, visualization and calculating midpoint*"). These annotations often appreciated the problem's mathematical generativity while simultaneously suggesting the teacher should provide additional scaffolding or clarity to support student access (e.g., "*Teacher must make it clear that points J & D are randomly selected*," "*Include specific temperature. Start with room temperature so that the student can differentiate the boiling and freezing temp*.")*.*U.S. teachers, by contrast, attended to the problem less through its mathematical generativity than through its accessibility to students. Their comments more often anticipated where the task's wording or lack of given measurements might create confusion (e.g., "*The vagueness of 'from one of the sides' could really trip up a lot of students*"), and where they appreciated the problem, they did so for its real-world relevance rather than its explorative quality (e.g., "*I love the real-world relevance of the problem*"). Thus, while both groups remarked on the problem at similar rates, non-U.S. teachers tended to foreground its conceptual richness, whereas U.S. teachers foregrounded student access and clarity.

In summary, the same lessons elicited different responses depending on teachers' pedagogical contexts. For U.S. teachers, the lessons departed from what they may have expected exemplary PD materials to model—particularly around student voice and discourse. For many non-U.S. teachers, the same instructional moves were characterized positively, with attention focused on problem quality and teacher clarity. This distinction suggests that what teachers find worth remarking upon is not universal but shaped by the instructional assumptions and professional expectations of their particular context.

Conclusion

Though the lessons were intentionally designed to depart from some expectations teachers might hold for exemplary professional development materials—particularly those aligned with U.S. reform-based teaching expectations (NCTM, 1991)—what teachers found worth remarking upon was not universal. Our findings suggest that teachers from different pedagogical contexts bring different implicit assumptions about teaching and learning to their reading of the same lesson representation. These assumptions may be shaped not only by their classroom traditions but also by what they expect from representations of instruction in a professional development setting (Schwarts et al., 2025). What U.S. teachers frequently identified as a significant instructional concern—students not actively engaging with mathematical problems was less salient to teachers from other pedagogical contexts, who attended instead to problem characteristics and mathematical precision. Yet, an important feature aligned with U.S. Standards—the use of novel problems to usher in new content—was more appreciated by non-U.S. teachers. These findings remind us that pedagogical approaches like teaching through problems

(Lampert, 2001) are not culturally neutral. What counts as good teaching, or as a departure from it, appears to be shaped by the particular instructional traditions and professional contexts in which teachers work.

Several limitations warrant consideration. First, our sample of non-U.S. teachers was relatively small (n = 28) and came from only four countries, limiting generalizability. The "non-U.S." category is heterogeneous, combining teachers from pedagogical traditions that may themselves differ substantially. Second, we analyzed written asynchronous annotations rather than synchronous verbal discussions or teachers' reflections on their own classroom practice. Teachers' written annotations may not fully capture their pedagogical reasoning; future work could examine synchronous discussions alongside annotations to better access the reasoning behind them. Third, we examined teachers' responses only by national context (U.S. vs. non-U.S.) and did not distinguish them by lesson (Algebra vs. Geometry). The lesson itself (Algebra vs. Geometry) could be another variable shaping teachers' responses. Analyzing annotations by lesson would be a useful direction for future work.

A FRAMEWORK FOR CATEGORIZING TEACHERS' EVALUATIONS OF STUDENTS' RESPONSES TO SIGNIFICANCE TESTING PROBLEMS

Francisco Sepúlveda Vega
Cinvestav, México
francisco.sepulveda@cinvestav.mx

Ernesto Alonso Sánchez
Cinvestav, México
esanchez0155@gmail.com

We propose a framework to characterize how in-service high school teachers evaluate students' written responses to significance-testing problems solved through an informal simulation-based approach. The framework emerged from a design research study conducted within a short professional development course involving 16 teachers. Grounded theory was used to code teachers' written analyses of student responses. Four main categories were identified: brief, evaluative, descriptive, and interpretative, each with two subcategories. These results were compared with similar frameworks in the literature to highlight the subtle but meaningful contributions we report. The framework may contribute to support research and professional development focused on fostering teachers' interpretations of student reasoning in statistics.

Keywords: Professional Development, Assessment, Data Analysis and Statistic

Research on mathematics teachers has shown a sustained interest in characterizing the knowledge required to teach effectively. Within this line of work, several theoretical frameworks of teachers' professional knowledge have been proposed (e.g., Ball et al., 2008; Fennema & Franke, 1992; Flores-Medrano et al., 2014). Among the components identified in these models, particular attention has been paid to the importance of knowing students' thinking. For instance, Fennema and Franke (1992) long ago highlighted the knowledge of learners' cognitions in mathematics, understood as knowledge of how students think, learn, and encounter difficulties with specific mathematical content. More recently, the Mathematical Knowledge for Teaching framework identifies Knowledge of Content and Students (KCS) as a central subdomain that integrates mathematical understanding with knowledge of students' reasoning, errors, and ways of thinking (Ball et al., 2008; Depaepe et al., 2013).

As statistical reasoning differs from mathematical reasoning (Wild & Pfannkuch, 1999), teachers need specific knowledge for teaching statistics (Groth, 2007). Accordingly, different frameworks have been developed to characterize Statistical Knowledge for Teaching (SKT), most of which highlight the importance of KCS (e.g., Burgess, 2006; Groth, 2013; Batur & Baki, 2024). However, little is known about how teachers interpret students' reasoning in statistics. At the high school level, we highlight the work of Nagle, Casey, and Carney (2018), who investigated teachers' noticing in a statistical task related to the line of best fit using an informal approach, and Shin (2020, 2021), whose studies involved preservice teachers analyzing video clips from a high school statistics class. In another study, Yilmaz and Yetkin (2023) analyzed preservice mathematics teachers' work during three cycles of lesson study implemented with seventh-grade students concerning bar, pie, and line graphs. Noticing is the common framework across these four studies.

On the other hand, research on hypothesis and significance testing in statistics education has focused mainly on teachers' content knowledge (e.g., Batanero et al., 2018; Matuszewski, 2018). However, we have not found studies related to teachers' KCS in this specific area.

With this perspective, we conducted a study within a short professional development course at a public upper-secondary school, working with in-service teachers, and building on our recent research on students' reasoning about significance tests and sampling distributions from an

informal, technology-supported perspective (Sánchez et al., 2024). The general question we posed was: *How do teachers evaluate students' written responses to significance-testing problems solved through an informal approach using simulated sampling distributions?*

In the process of analyzing the data to address this question, a framework emerged that organizes teachers' responses to a task intended to prompt them to analyze the students' reasoning. The aim of this article is to present this framework.

Background

Evaluation and Formative Assessment

The term *evaluation* in English is often associated with summative practices, whereas *assessment* more commonly refers to processes embedded in everyday teaching. This distinction does not exist in Spanish, where the word *evaluación* is used for both contexts, and more broadly to refer to estimating students' knowledge. Formative assessment (translated into Spanish as *evaluación formativa*) has been extensively researched as a way of examining students' work with the aim of supporting their learning and providing effective feedback. This has remained a relevant research topic within the PME-NA community, even in recent years (e.g., Confrey, 2024; Namakshi et al., 2024; Staples & Rostkowski, 2025), yet it has still been described as precarious (Confrey, 2024).

In contrast to these broad uses of assessment and evaluation, when analyzing teachers' interpretations of student thinking from a *noticing* perspective, teachers' responses are often described as "evaluative" referring to interpretations in which teachers acknowledge or judge the merits, affordances, or limitations of students' processes (e.g., Nagle et al., 2015; Yilmaz & Yetkin, 2023). This reflects a judgment-oriented use of the term *evaluation*, which foregrounds interpretation while setting aside other common aspects, such as grading or feedback. This clarification helps define the scope of our research questions, while also situating them within the literature. In this report, we use the term *evaluation* as a literal translation of the Spanish word to refer to teachers' estimating students' knowledge when analyzing student responses, not necessarily implying judgment or interpretation.

Developing Knowledge of Content and Students Through the Analysis of Student Work

As we explain below, the procedure used to elicit teachers' knowledge about students consisted of asking them to analyze students' written responses to tasks on significance testing. In practice, this prompt became a task of evaluating students' answers. Our review of the literature indicates that such evaluative work is a common practice for fostering KCS (e.g., Baldinger, 2020; Nagle et al., 2018; Namakshi et al., 2024). The written analysis of student responses offers several advantages over other professional development formats. For instance, written interactions can help teachers set aside preconceptions about students, as well as concerns related to classroom management, discipline, and curricular pressures that often dominate their attention (Crespo, 2000; Talanquer et al., 2015). Moreover, this format allows teachers to engage collaboratively in examining student thinking and to question and extend their own mathematical ideas (Crespo, 2000).

Research has identified patterns in how teachers evaluate students' written reasoning. Teachers who make brief or general inferences tend to adopt an evaluative or judgment-based orientation, often attributing students' difficulties to lack of attention, effort, or memory. In contrast, teachers who seek to understand students' thinking display a more interpretive orientation, focusing on specific features of students' reasoning (Crespo, 2000; Talanquer et al., 2015). Studies also report on the relationship between the nature of students' responses and teachers' interpretations. For example, Talanquer et al. (2015) found that selecting correct

answers can lead teachers to overlook misunderstandings present in students' justifications, whereas focusing on incorrect responses may draw attention away from productive elements in students' reasoning. Finally, even when teachers attempt to interpret student thinking, limited content knowledge can hinder their ability to make sound inferences about students' understanding (Nagle et al., 2018; Talanquer et al., 2015).

The literature identifies several factors that can strengthen teachers' capacity to evaluate student reasoning, including solving the same tasks as students before analyzing their work (Baldinger, 2020), working in small collaborative groups (Crespo, 2000; Yilmaz, 2022), and participating in professional development focused on student thinking (Jacobs et al., 2010; Yilmaz, 2022). All three features were incorporated into the present study.

We acknowledge that referring to students' written responses as students' thinking or reasoning (e.g., Namakshi et al., 2024) may be controversial, as thinking is a mental activity and the relationship between students' thinking and what they write is complex. For instance, students' verbal justifications may include additional reasoning not documented in written responses (Staples & Rostkowski, 2025). We assume, following Staples and Rostkowski (2025), that written justifications are expected to include claims, evidence, and reasoning; however, to avoid overinterpretation, we refer to students' answers simply as responses.

High School Students' and Teachers' Conceptions of Significance Testing

Knowledge of content and students in the domain of significance testing is informed by a broad body of findings from statistics education research. This literature documents recurring patterns in how students and teachers understand key ideas and the difficulties they encounter. In what follows, we highlight some results that are particularly relevant to this study.

A common tendency among students is to believe, inappropriately, that the purpose of a significance test is to confirm or prove that a hypothesis is true (or false; Batanero, 2000). Confusion is also frequently reported among three related distributions: the sample distribution, the sampling distribution, and the population distribution (Inzunza & Jiménez, 2013). It is worth noting that similar difficulties have been documented not only in students but also in both preservice and in-service high school teachers (Batanero et al., 2018; Haller & Krauss, 2002; Matuszewski, 2018; Thompson et al., 2007).

When an informal approach supported by computer simulation is used, students often struggle to coordinate two different perspectives: the real world, in which the empirical sample is collected, and the hypothetical perspective represented by the SSD, in which the null hypothesis is assumed to be true (Case & Jacobbe, 2018; Sánchez et al., 2024; Silvestre et al., 2024).

Method

The purpose of our study was to characterize how in-service high school teachers evaluate students' written responses to significance-testing problems solved through an informal approach using simulated sampling distributions (SSDs). The specific aim of this article is to present a general framework to describe and anticipate the ways in which teachers evaluate students' responses to such problems. This framework emerged from activities carried out in a professional development course. The methodological approach underlying the research from which the framework emerged was design research (Bakker, 2018).

Participants

Sixteen in-service teachers from a public upper secondary school in Mexico voluntarily participated in a professional development course offered during the inter-semester break. Of these, nine held graduate degrees (three doctoral and six master's degrees). Seven had received training to teach statistics, and five had taught the topic of hypothesis testing. Two participants

did not provide their background information. Among the 14 teachers who did provide data, the mean number of years teaching math or statistics at the upper secondary level at the time of the course was 15.6 years, and the median was 11.5 years. The authors of this article, together with a respected teacher at the same school served as instructors for the course.

Procedure

A 20-hour intersession course, organized into five four-hour sessions, was delivered to teachers remotely and synchronously. It was conducted in five sessions of four hours each and aimed to support teachers in two directions: (1) solving significance testing problems from an informal approach with the aid of computer simulation, and (2) fostering the analysis of students' reasoning by examining their responses to significance testing problems. Session 1 introduced the course, reviewed some fundamental statistical concepts, and taught participants how to generate SSDs using the software Fathom. Session 2 focused on solving significance tests problems from an informal perspective with the support of simulation. Subsequently, teachers solved three problems and compared the traditional approach with the simulation-based approach. Sessions 3, 4, and part of Session 5 were devoted to problems in which teachers evaluated students' responses to significance testing tasks, identified and explained the ways of reasoning that led students to their answers.

Instrument

Ten student responses to significance tests problems were selected for teachers to analyze. These responses were part of a data set from a previous study on the same topic conducted with students (García-Ríos, 2017). The statistical problems had been previously solved by the teachers during the first session of the course. In selecting the student responses, the researchers sought examples that displayed misconceptions or relevant features of students' reasoning, with the aim that teachers would identify them. The 10 responses were administered across the sessions as follows: three in Session 3, four in Session 4, and three in Session 5. Teachers worked in pairs during these Sessions. As an example, one of the tasks, called Situation, administered in these sessions is presented in Table 1. The students' response in this Situation illustrates the challenge of coordinating a real-world perspective with a hypothetical one.

Data Analysis Procedure

The analysis followed principles of Classic Grounded Theory (CGT), a rigorous and systematic methodological approach for generating an emergent, inductive, and abstract conceptual theory (Glaser & Strauss, 1967). A feature that distinguishes CGT is that the analysis is not based on pre-established categories or theoretical frameworks. To do so, the process began with coding through a constant comparison of the data. With additional procedures, such as saturation and theoretical coding, categories, their properties, and their mutual relationships were identified, as well as the emergence of a central category (Birks & Mills, 2015).

In our case, the first author coded all the responses provided by pairs of teachers across the different situations. Each code was subsequently discussed with the second author to clarify its meaning, merge related codes, and define the names and characteristics of each category. This process was conducted twice throughout the research to support category saturation.

We also highlight that two literature reviews were conducted. The first was an a priori review, which helped contextualize and define the research problem. This review focused on significance testing from an informal approach and on teachers' knowledge of significance testing. The second was an a posteriori literature review. After completing the coding process and developing the categories, we conducted a literature review related to the main category

(evaluation) in order to frame and deepen our results and extend the discussion. In this a posteriori review, we found noticing frameworks to be particularly relevant to our study.

Table 1: Example Task Situation

Context	High school students with no prior background in statistical inference generated SSDs in Fathom and used them to solve a problem. The following responses represent intuitive student conceptions. For each response, answer the question: How did the students reason to reach their conclusion?
Problem 1	It is believed that half of the population that drinks cola prefers Pepsi and the other half prefers Coke. Coca-Cola claims that the majority (more than 50%) of cola drinkers prefer Coke over Pepsi. To support this claim, the company surveyed 60 randomly selected people who regularly consume cola. Out of the 60 participants, 35 preferred Coca-Cola. Is the sample information sufficient to reject the hypothesis that the population is evenly split?
Student Response	[They simulated 500 samples $n = 60$ from an urn with $p = 0.5$ and generated the SSD.] The hypothesis does not hold because we took the surveys from 31 responses onward that preferred Coke, which gives a total of 233 surveys. If this is multiplied by the 60 people in each survey, we obtain a total of 13,980. Meanwhile, from 30 (which represents 50%) and below, there are 267 surveys, and multiplying this by the 60 people gives a total of 16,020, which represents a quantity greater than 50%. That is, more than 50% of the population does not prefer Coca-Cola. We are confident in this conclusion because we relied on the results shown in the graph, considering that the total number of people in this case is 30,000.

Results

In this section we present the categories that constitute the evaluation framework proposed in this study. The categories and their properties emerged through an open coding process in which common response patterns were identified in at least two responses from different teams, whether from one activity or another. The categories are not mutually exclusive, since some responses display characteristics that allow them to be classified into two or more categories.

Below, we provide a brief definition of each category and include a characteristic example of a teacher response classified within it. The number in parentheses indicates the frequency of responses classified in the corresponding category or subcategory.

As an example of how the coding happened, the category “brief” was initially called “conclusive” and later “immediate.” The term “conclusive” was assigned because teachers appeared to be oriented toward reaching conclusions; however, it did not reflect the brevity of their responses. The term “immediate” was then considered to describe the absence of mediation. However, since the synthetic subcategory could be both mediated and brief, “brief” was ultimately chosen as a more general characteristic that encompasses both the reductionist and synthetic subcategories.

Brief Response

Responses classified in this category (24) are short, concise, and sometimes blunt statements in which the teacher highlights an isolated feature of the student’s response to comment on the

underlying reasoning. This category is divided into two subcategories, *reductionist* and *synthetic*.

The reductionist responses (19) are general and superficial, since although they mention a feature that is relevant to the student's response, they fail to capture a key aspect of the argument behind it. For example, in response to the question *How did the student reason?* one pair answered: *Through the distributions generated in Fathom.* This response does not reflect any key element of the students' argument.

In contrast, the synthetic responses (5), despite being brief, point out or interpret specific aspects of students' reasoning. For instance, other team's response is as follows: *By taking the 500 samples of size 60 as a population.* This team identifies an important aspect of the students' reasoning—namely, that they confuse the SSD with the population—although no further elaboration is provided.

Evaluative

Responses in this category (30) judge whether the student's response, or part of it, is correct or not according to the teacher's expectations. Their explanations are likely variants of the argument that a teacher would give to a student when assigning a grade on an assessment. This category is also divided into two subcategories: *absent* and *present*.

Responses classified as absent (20) judge students' productions based on aspects that do not appear in the response but are considered by the teacher as elements that should be present. This subcategory is usually identified through negations, for example: *does not consider variability*.

Responses classified as present (10) judge what is explicit in the response, mentioning at least one aspect to support the judgment. For example: *They did correctly interpret and analyze what was obtained in the simulation.*

Descriptive

Responses in this category (43) merely describe part or all of the procedure represented in the student's response without adding anything beyond what is written there. Typically, they paraphrase some or all of the expressions present in the student's response and occasionally replace vague terms with more precise ones. In general, these responses consist of two or more sentences. This category is divided into *procedural* and *explanatory* subcategories.

The procedural subcategory includes responses that focus on general aspects of the procedure by paraphrasing students' expressions and using their same vocabulary. For example, one pair of teachers wrote: *They consider the sample size and multiply it by the number of samples.* This operation is indeed performed by the students, but the response adds nothing further.

On the other hand, responses classified as explanatory translate words from the students' vocabulary into the corresponding statistical or mathematical terms or add formal terminology to specify what the students are doing. In addition, explanations or hypotheses about how students reasoned are sometimes formulated. For example, one pair of teachers stated:

> Their reasoning in the significance test was correct; the procedure is correct, since they calculated the percentage of defective pieces of at least 16 and contrasted it with the p-value, finding that the result is typical in the sample, and concluding that the machine should not be repaired.

In this response there is some confusion on the part of the teachers, since the "percentage of defective pieces of at least 16" corresponds to the p-value, and the comparison should be made with the 5% significance level. What is important in this response is that the teacher introduces the term *p-value* to indicate aspects of what the student is doing.

Interpretative

Responses in this category (47) make interpretations; that is, they go beyond what is

observed by offering an interpretation of the students' responses, or parts of them, either from a statistical or a didactical perspective. Two subcategories are identified: *statistical* and *didactical*.

Teacher responses classified in the statistical subcategory (25) include statistical concepts and terms that are not explicitly mentioned in the analyzed response. For example, one team's answer is: *They use the method correctly, although we observe a slight confusion with the 5%, since they consider defective pieces when the value actually refers to samples.* In this response, the teachers suggest that the students should have used the term *sample* when referring to the 5% significance level.

In the didactical subcategory (22), interpretations are made about students' knowledge, reasoning, difficulties, or curricular factors. For example, another pair of teachers stated: *They reasoned using it as a statistical rule for decision making. The rule is: the result must be less than or equal to 5% of the pieces in order to consider a result.* The teachers recognize and highlight the central point of the reasoning in the student's response and judges it as appropriate.

Table 2 presents the categories, subcategories, and their frequencies. The total frequency is 144 because some responses were assigned to two or more categories.

Table 2: Frequencies of Categories and Subcategories

Brief (24)		Evaluative (30)		Descriptive (43)		Interpretative (47)	
Red.	Syn.	Abs.	Pres.	Proc.	Expl.	Stat.	Did.
19	5	20	10	25	18	25	22

Note. Red. = Reductionist; Syn. = Synthetic; Abs. = Absent; Pres. = Present; Proc. = Procedural; Expl. = Explanatory; Stat. = Statistical; Did. = Didactical.

Discussion and Conclusion

The categories of the framework are similar to some categories proposed in other studies that share purposes and methodological features with ours. For example, Crespo (2000) initially asked preservice teachers to differentiate between descriptive and interpretative responses. She also noted that students held evaluative attitudes that, because of the course she implemented during a long period, shifted toward interpretative attitudes. We also found several points of convergence with Nagle et al. (2018), who worked with in-service secondary school teachers on the line of best fit. In their results, they also proposed four codes to describe teachers' interpretations of student work. However, their framework contrasts with ours in that, although we agree on several observations, the way of organizing them is different. The codes they propose are: (1) evaluative affordances (2) evaluative deficits, (3) interpret students process, and (4) interpret students understanding. Making a general comparison and setting aside caveats related to differences in the statistical content of the tasks, the first two codes proposed by Nagle et al. can be grouped within our Evaluative category. However, whereas their framework emphasizes identifying affordances or deficits in students' answers, ours focuses on whether teachers evaluate what is present in students' answers or what is missing, so that what is present may still reveal deficit. Also, their last two codes are similar to our descriptive procedural and our interpretative category, in the case of describing process we identify that teachers can do it by paraphrasing student's work or by adding teachers' knowledge, we believe this distinction is important for purposes of developing teachers' knowledge of content and students. In their framework, Nagle et al. introduce levels of sophistication based on whether teachers' claims are supported by evidence from student work, an aspect that could strengthen our framework. By contrast, our interpretative category does not require teachers to infer students' understanding

which we regard as more aligned with research-oriented analysis; instead, it centers on interpreting the reasoning expressed in the student's response, either from a statistical or pedagogical perspective. This distinction becomes particularly relevant when aiming to support formative assessment practices.

It has been reported that most teachers tend to describe or evaluate students' productions and, in general, find it difficult to interpret their reasoning (Crespo, 2000; Nagle et al., 2018; Talanquer et al., 2015; Yilmaz, 2022). Our results show that interpreting students' reasoning in the context of significance testing with simulation is also challenging for teachers. This difficulty may be associated with teachers' limited content knowledge (Nagle et al., 2018; Talanquer et al., 2015), the complexity of students' reasoning (Talanquer et al., 2015), or teachers' lack of experience both teaching the content and analyzing students' responses (Jacobs et al., 2010). It is plausible that the cause involves a combination of these three factors.

In the argument that follows, some plausible hypotheses are proposed. It is worth noting that in-service teachers may respond to the tasks somewhat differently from preservice teachers (Crespo, 2000). For example, in-service teachers have experience repeatedly facing the problem of grading large numbers of students' exams. This implies that they develop evaluative habits consisting of deciding whether a response is correct or not and providing a brief, and probably stereotyped, justification to convince the student of the error. Thus, when confronted in this study with the task of analyzing students' responses, their evaluative habits naturally emerged; that is, they associated the task with the practical problem of assessment, and their responses fell into the "brief" or "evaluative" categories.

By contrast, some of the experienced in-service teachers who participated in our study had completed graduate studies, some in Statistics and others in Mathematics Education. The latter were highly likely to have been introduced to tasks involving the interpretation of data derived from students' work and were therefore more inclined to offer responses situated at the interpretative level. Although these teachers may initially have applied their evaluative habits, within the dynamics of the course they shifted toward an interpretative stance (Crespo, 2000).

Under these considerations, we formulated the hypothesis that the categories of the framework are of three types. The first comprises the brief and evaluative categories, which reflect dispositions oriented toward solving practical problems of assessment. The second consists of the descriptive category, which is transitional in nature, as its purpose is merely to clarify the student's response without an interpretation intent. The third type is formed by the interpretative category, which reflects a theoretical disposition in which the problem to be addressed is that of increasing teacher's understanding. This is because the identification of a pattern in students' thinking or of a misconception does not, in itself and immediately, suggest consequences for the teacher's instructional practice (Groth, 2013; Jacobs et al., 2010).

In line with grounded theory, the central concept that emerged from our analysis was evaluation. Our initial research question asked *How do teachers develop knowledge of content and students by evaluating students' written responses to problems with statistical content?* Yet, constructs such as models of students' thinking, commonly used by researchers to conceptualize knowledge of content and students (Groth, 2013; Liang, 2023), may be experienced by teachers as foreign or abstract, whereas assessment is deeply embedded in their professional practice. This tension itself constitutes one of the findings of our study.

One limitation of this study is that teachers' work was examined outside the context of classroom practice. We were also unable to observe how the course influenced teachers' instructional practices. Nonetheless, the findings may inform future professional development

initiatives. A further limitation concerns the limited time available to support the development of teachers' understanding of the informal approach. Increased teacher content knowledge would likely lead to different research outcomes.

ASSESSING PRIMARY SCHOOL TEACHERS' PERCEPTIONS OF PROFESSIONAL DEVELOPMENT USING A NOVEL RESEARCH INSTRUMENT

Jamiu Temitope Sulaimon
North Carolina State University
jtsulaim@ncsu.edu

Professional development (PD) is widely regarded as a key component of teacher growth. Existing measures assess teachers' satisfaction with PD, but few do so while also capturing the PD opportunities available to teachers, teachers' participation in PD, or the challenges teachers encounter in PD. The current study describes a researcher-designed instrument used to survey 228 public and private primary school teachers in Nigeria. Descriptive revealed that a range of PD formats were available to teachers, but overall teacher participation was moderate. Major challenges were inadequate financial incentives, insufficient institutional support, excessive workload, and a lack of interest. The results show that the designed instrument produced actionable evidence on teachers' access to PD, particularly in less-studied settings.

Keywords: Professional Development, Teachers' Engagement, Primary School

Today, the demands of the changing educational ecosystem have redefined the competencies and roles expected from teachers (Ekinci & Akar, 2019). In addition to traditional pedagogical competencies, educators are expected to demonstrate mastery of digital pedagogy and STEAM-based teaching, inclusive pedagogy, and the ability to understand the changing curriculum and assessment systems. Consequently, continuous professional development (PD) is needed to support teachers' learning.

The quality and availability of PD are critical to teachers' effectiveness and growth, especially when classroom demands are evolving. High-quality PD is characterized by being practice-based, collaborative, and effective in the long-term and must be facilitated by coaching or follow-up to enhance the chances of significant changes in teaching (Darling-Hammond et al., 2017; Desimone and Garet, 2015). The study of PD access is particularly instructive in the context of Ilorin South Local Government Area (LGA) of Kwara State in north-central Nigeria. The primary schools in this LGA comprise government-funded public schools and privately owned schools. Continuous professional learning is a requirement of the Teachers Registration Council of Nigeria (TRCN) for all registered teachers, but schools' capacity to implement this requirement varies across the region (Ajadi, 2020; Ojo & Emeka-Nwosu, 2023). This context is important to consider when interpreting the patterns of PD access reported in this study.

Notably, educators can make rational professional choices not to participate in PD, such as when they believe a training is not relevant to classroom realities, offered as isolated experiences with no follow-up, scheduled in a manner that is incompatible with their workload or necessitates personal expenses that are not institutionally subsidized. Studies show that the interaction of PD design, school conditions, and professional judgement of teachers determine their level of participation (Darling-Hammond et al., 2017; Opfer & Pedder, 2011). This implies that enhancing learning outcomes is not just about pushing attendance but also providing equitable access to well-designed PD with sufficient resourcing and long-term support, particularly at the primary level where the quality of teaching is foundational (Ssh & Jacob, 2020).

The availability of PD opportunities varies significantly among teachers. Despite its importance, access to PD is uneven, resulting in unequal opportunities for teachers to engage in

meaningful learning experiences. Although nations invest significant financial resources in PD programs to improve teachers' competencies and students' academic performance (Popova et al., 2022), access to high-quality PD remains unevenly guaranteed. While studies found that professionally designed PD models, including workshops, in-service training, mentoring, professional learning communities, and technology-based learning environments, can positively affect the quality of the instruction provided to professionals (Darling-Hammond et al., 2024; Yoon et al., 2020; Lauer et al., 2014), the involvement of teachers however, is usually determined by the resources, leadership support and organizational structures that are present within their educational institutions.

Beyond unequal access, structural and situational barriers limit teachers' meaningful participation in PD. Empirical research also suggests that insufficient funding, unequal budgetary distribution, ineffective professional support structures, and lack of follow-up mechanisms are also major limiting factors to teacher participation in PD programmes (Bowman et al., 2022; Saleem et al., 2021). Even when equitable access and active participation are present, situational constraints may hinder sustained engagement. Structural barriers that teachers might face include a lack of funding, excessive workload, poor leadership support or poorly planned programmes. In other instances, where PD opportunities might exist, they are scheduled at inappropriate times or are not relevant to teachers' needs. Such obstacles may decrease motivation, limit long-term involvement, and eventually limit the influence of PD on instructional practice.

In spite of the acknowledged importance of PD, existing research instruments employed to study teachers' experiences of PD are limited (Ritcher & Ritcher, 2024; McChesney & Aldridge, 2018). It can be estimated that the most prevalent forms of large-scale surveys and institutional assessments assess the level of teachers' satisfaction or their impressions about the quality of PD (Popova et al., 2022). Scholars have developed a variety of instruments to measure different aspects of teachers' PD. Indicatively, scales developed within the Teaching and Learning International Survey (TALIS) instrument assessed the professional practices, background, development activities, and teaching conditions of teachers on an international scale, which provided insight into how contexts influence teachers' level of engagement with PD opportunities (Ainley & Carstens, 2018). Likewise, national survey instruments like the TALIS 2018 teacher questionnaire have included subscales of PD barriers, with teachers having to rate the importance of factors like the absence of institutional support, time-related conflicts, and relevance of subject content to their participation in professional learning (Yuner, 2022). Additionally, large-scale surveys have also come up with instruments that focus on the features of PD programmes.

Although these tools provide significant information regarding teachers' PD, they possess significant limitations in comparison to the objectives of the present study. Few instruments are available for the systematic evaluation of whether teachers are able to access PD equitably and participate in it, or capture the barriers that constrain their involvement in PD (Ndlovu et al., 2024). Large-scale measures like TALIS are cross-nationally comparable and tend to capture general measures of PD participation and satisfaction rather than the systematic measures of accessibility, barriers to engagement, and participation patterns. Other instruments, including those that focus on the characteristics of PD or workplace learning, are more likely to concentrate on the quality or characteristics of PD programmes, as opposed to the circumstances in which teachers can fairly access and participate in PD opportunities or the circumstances that hinder participation. Such a gap in measurement tools highlights the necessity of a specific tool, such as the Assessment of Professional Development Programmes among Primary School

Teachers Questionnaire (APDPPSTQ). In contrast to generic PD surveys, the APDPPSTQ is designed to systematically measure the availability and type of PD, as well as the level of participation and the barriers teachers face.

Theoretically, the APDPPSTQ is based on three complementary frameworks. The availability subscale was informed by Desimone's (2009) four core features of effective PD: content focus, active learning, coherence, and duration, as well as collective participation. Second, the participation subscale was guided by the TALIS conceptual framework (Ainley & Carstens, 2018), which was used to guide the items, which were parallel to internationally validated indicators of frequency and type of engagement. Third, the barriers subscale was based on the complexity model of teacher professional learning developed by Opfer and Pedder (2011), which posits that barriers (such as workload, funding, and institutional culture) lie between the availability of PD and teacher participation.

Thus, the three dimensions of access, willingness and barriers are interrelated and influence teachers' participation in PD. Access is the base, without access, teachers can't be involved in opportunities that are not available to them. Availability does not, however, ensure participation, but rather teachers' willingness to participate is dependent on the relevance, quality and supportiveness of the opportunities offered. Meanwhile, structural and situational barriers can be both access barriers and can also dampen motivation over time. So, measuring just one or two of these dimensions might lead to a partial assessment of teachers' PD involvement. All three dimensions need to be taken into account for a comprehensive assessment.

Methodology

For this research study, the researcher adopted a quantitative descriptive survey research design to assess PD programmes among primary school teachers in Ilorin South Local Government Area of Kwara State, Nigeria. This context was chosen because it is a microcosm of the overall primary education system in Nigeria as it has both publicly funded schools, managed by the State Universal Basic Education Board (SUBEB) and privately owned schools, with teachers ranging from the Nigeria Certificate in Education (NCE) to postgraduate education. I used a structured questionnaire to sample teachers' perceptions about PD programmes. The population of the study comprised all public and private primary school teachers within Ilorin South Local Government Area. Stratified and simple random sampling techniques were used to select 228 primary school teachers.

I constructed an instrument titled "Assessment of Professional Development Programmes among Primary School Teachers Questionnaire" (APDPPSTQ). APDPPSTQ was subdivided into four sections: Section A: demographic distribution of the respondents (Gender, teachers' qualification and school type). Section B: with 10 items measuring available PD programs on four Likert scales of Strongly Agree, Agree, Disagree and Strongly Disagree. Section C with 10 items measuring the level of participation in PD programs on a 3-point Likert scale of Always, Sometimes, and Never. Section D challenges hindering primary school teachers from participating in PD programs, on four Likert scales of Strongly Agree, Agree, Disagree and Strongly Disagree.

The items of the APDDPSTQ were developed based on the existing conceptual and empirical frameworks of teacher PD. The availability and participation sections were informed by the framework of Desimone (2009) on the key characteristics of effective PD and survey designs of major international surveys, including the OECD Teaching and Learning International Survey (TALIS) (Ainley & Carstens, 2018). The participation items are conceptually related to Garet et al. (2021), who also note that frequency and collective engagement are important aspects of PD

involvement. Empirical literature that informed the challenges section was the identification of structural and contextual barriers to PD participation that include time constraints, funding limitations, administrative support, and motivational factors (Avalos, 2011; Opfer & Pedder, 2011). All these frameworks were used to inform the item generation and provide conceptual consistency with the existing research.

The research was carried out in Ilorin South Local Government Area of Kwara State in Nigeria, an urban district, comprising of both publicly and privately owned primary schools. These schools differ in terms of administrative structures, funding schemes, and institutional support, and these differences can affect teachers' access to PD opportunities. The sample consisted of 228 primary school teachers in both the public and the private schools in the district. The demographic profiles of the respondents differ in their academic qualifications, years of teaching experience, and type of school, which represents the diversity of the teaching workforce in the region. All respondents were actively involved in classroom teaching at the primary level during data collection and had different levels of exposure to PD programmes. Their responses revealed how PD opportunities are offered, whether and to what extent teachers participate, and what difficulties they encounter during this process.

The face and content validity of the instrument were assessed by three experts in education; their comments and observations were used to draft the final instrument. The data obtained from the study were analyzed using descriptive statistics (frequency, percentage, mean and standard deviation) and inferential statistics, including an independent sample t-test and analysis of variance at a 0.05 level of significance. The internal consistency of the instrument was assessed using Cronbach's alpha. The questionnaire was pilot-tested with 20 participants who were not included in the main study. The analysis indicated good reliability for the overall instrument ($\alpha = .89$).

The Instrument

The demographic distribution of teachers comprised gender, school type and qualifications. Out of 228 primary school teachers who participated in the study, 90 (39.5%) were male, while 138 (60.5%) were female; however, more female teachers participated than their male counterparts owing to the high concentration of women in the teaching sector in this region. In addition, out of 228 primary school teachers who participated in the study, 82 (36.0%) were from public schools, while 146 (64.0%) were from private schools; however, more private school teachers participated than their public school counterparts. Finally, of the 228 primary school teachers who participated in the study, 182 (79.8%) were Nigeria Certificate in Education (NCE) holders, 26 (11.4%) were BSc/B.Ed/Higher National Diploma (HND) holders, while 20 (8.8%) were M.Ed/ PhD holders.

Professional Development Availability and Access

The overall data from the availability of the PD opportunities in the primary schools in Ilorin South LGA in Table 1 show that the opportunities for PD are reasonably wide in the primary schools in the LGA (item means ranging from 2.96 to 3.28 on a 4-point scale). In particular, the most highly rated items, Kwara Learn Initiatives ($M = 3.28$), academic conferences ($M = 3.28$), and further training opportunities ($M = 3.28$), indicate that both government-coordinated and institutionally supported formats are considered relatively accessible. Exposure to global best practices was rated the lowest ($M = 2.96$), suggesting that international alignment in PD is a gap area. The patterns indicate that the instrument is sensitive to variation in PD provision within contexts, rather than yielding uniform patterns of response, which is an indicator of discriminative validity.

Table 1: Mean and Standard Deviation of the Available Professional Development Programmes among Primary School Teachers in Ilorin South Local Government Area

S/N	Items	Mean	SD
1	Government-sponsored STEAM capacity-building seminars are available for teachers.	3.18	0.65
2	Continuous Professional Development training programmes abound for teachers.	3.09	0.75
3	Teachers can easily partake in development courses for in service.	3.17	0.69
4	School administrators sponsor professional development programs for teachers from time to time.	3.05	0.76
5	Teachers are often exposed to current global best practices in the teaching profession from time to time.	2.96	0.81
6	Teachers have a chance to attend Kwara Learn Initiatives to improve their teaching practices.	3.28	0.63
7	Webinars are available for teachers to improve their teaching methodologies.	3.13	0.68
8	School managers sponsor teachers to attend academic conferences related to their field of specialization.	3.28	0.69
9	There are several opportunities for teachers to embark on further training to improve their academic credentials.	3.28	0.67
10	Teachers are exposed to digital skills training for teachers.	3.21	0.64

Professional Development Engagement

According to Table 2, results indicate that primary school teachers engage in PD programmes that are available occasionally. In this context, average participation is a weighted average of 2.14 on a 3-point scale (1 = Never, 2 = Sometimes, 3 = Always) meaning that most teachers engage in PD sometimes, but not consistently or reliably. This is not reflective of teachers' general lack of interest in professional learning, but rather reflects the episodic nature of professional learning in the context of structural conditions, such as financial pressures, workload stress, and insufficient institutional support, as evidenced by the challenges data. For instance, for in-service courses (M = 2.11) and Kwara Learn Initiatives (M = 1.95), the participation rates are among the lowest but the perceived availability rate is among the highest (Table 1), indicating a meaningful gap between availability and participation that should be addressed through institutional and policy interventions.

Table 2: Mean and Standard Deviation Showing the Level of Participation in Professional Development Programmes among Primary School Teachers in Ilorin South

S/N	Items	Mean	SD
1	I am a beneficiary of government-sponsored STEAM capacity-building seminars for teachers.	2.04	0.81

2	I have had the opportunity to attend Continuous Professional Development training programmes.	1.99	0.76
3	I have embarked on development courses for in-service teachers.	2.11	0.76
4	The administrators of my school sponsor professional development programs for teachers from time to time.	2.25	0.72
5	I have been exposed to current global best practices in the teaching profession in recent times.	2.16	0.79
6	I have had a chance to attend Kwara Learn Initiatives to improve my teaching practices.	1.95	0.89
7	I have upgraded my teaching methodologies through webinars.	2.11	0.74
8	I have been sponsored by my school to attend academic conferences related to my field of specialization.	1.92	0.84
9	I have embarked on further training to improve my academic credentials.	2.38	0.73
10	My digital skills have improved significantly as a result of my exposure to digital skills training for teachers.	2.45	0.69
	Weighted Mean	**2.14**	

Challenges Associated with Access to Professional Development

Results from Table 3 show that primary school teachers are experiencing a number of challenges that restrict their involvement in the PD programmes. Significant limitations include insufficient funding by the government and the administration of the private schools, the absence of regular promotion of teachers who are professionally developed, and the absence of institutional support. Other identified challenges include limited digital skills to develop professionally online, the absence of fringe benefits, and the unconcerned attitude of the school administrators towards PD programs. Teachers are further limited by high costs of in-service programmes, negative attitude towards change, workloads and administrative duties. The average scores of all the items were higher than the benchmark value, which proved that these factors are a major barrier to the participation of teachers in PD programmes.

Table 3: Mean and Standard Deviation Showing the Challenges Hindering Primary School Teachers from Participating in Professional Development Programmes

S/N	Items	Mean	SD
1	The Government and private school administrators do not allocate enough funds to engage teachers in professional development programmes.	3.29	0.69
2	Teachers do not have substantial time to participate in professional development programmes due to excessive workload.	3.05	0.76
3	Lack of institutional support discourages teachers from harnessing the diverse potentials of various professional development programmes.	3.24	0.64

4	Lack of the required digital skills hinders teachers from engaging in online professional development programmes	3.18	0.73
5	Negative attitude towards change impairs the rate of teachers' professional development.	3.06	0.74
6	Lack of fringe benefits reduces teachers' motivation for engaging in professional development programmes.	3.18	0.68
7	High costs of in-service professional development programmes limit teachers' professional development.	3.11	0.70
8	Lack of regular promotions for qualified and professionally developed teachers discourages teachers from enrolling in in-service professional development programmes.	3.25	0.71
9	The administrative work of teachers leaves no time for further professional development.	2.89	0.82
10	The lackadaisical attitude of school administrators towards professional development programmes reduces the morale of teachers to partake in professional development programmes.	3.15	0.69

Discussion

The survey instrument captured a wide range of PD opportunities, including government-sponsored STEAM programmes, capacity-building initiatives, continuous PD training, in-service programmes, webinars, academic conferences, digital skills training, and the Kwara Learn Initiative. Rather than a direct description of teachers' experiences, these results indicate the survey's capacity to record the types and perceived accessibility of PD formats in the local school environment. The response pattern aligns with previous literature showing that teachers are typically provided with various PD formats across different systems (Venter et al., 2024; Abd Ghani et al., 2023; Saleem et al., 2021). In this regard, the survey was able to determine the scope of PD programmes available within the region.

The instrument, however, fails to distinguish the programmes based on depth, duration and instructional coherence. Although the survey differentiates between event-based formats (e.g., seminars, webinars, conferences) and more structured initiatives (e.g., continuous PD training, in-service programmes, and the Kwara Learn Initiative), it does not capture actual measures of programme quality or long-term instructional effects. The current literature highlights the idea that long-term, consistent PD with follow-up elements is more likely to affect the instructional practice compared to the short-term, isolated training sessions (Darling-Hammond et al., 2017; Desimone & Garet, 2015). Thus, although the survey is a good way of recording the scope and comparative eminence of PD opportunities, it cannot be used to measure the substantive quality or long-term efficacy of those programmes.

The survey shows that teachers' level of involvement in PD programmes is average. Importantly, "average" participation does not mean that there were equal numbers of engaged and disengaged teachers, but that the weighted average score of 2.14 (on a 3-point scale) should be interpreted as episodic, irregular, rather than sustained, participation in professional learning. Qualitatively meaningful: Teachers seem to be engaged in PD when institutional conditions are conducive (e.g., administratively sponsored programmes, $M = 2.25$) but not when structural barriers are present (e.g., attendance at Kwara Learn Initiatives, $M = 1.95$, or academic conferences, $M = 1.92$). The differences between high availability scores and low participation

scores on the same items highlight a structural disconnect that the APDPPSTQ is well suited to uncover, which would not be as apparent in the aggregate TALIS-style data that would be likely to be seen in more diverse institutional settings. Although this trend aligns with previous research that has found moderate levels of engagement in other settings (Awodiji et al., 2022; Opper & Greer, 2022), the survey data raises more questions than just a mere comparison.

Findings also revealed that there are a number of challenges that impede the involvement of teachers in the PD programmes. These are poor funding by government and private school administrators, infrequent promotion of and incentives for professionally developed teachers, institutional support, low digital skills, and administrative dedication to PD programs. Other limitations like the high programme costs, negative attitude towards change, work overload and administrative burden also minimise the participation of teachers. These results are in line with Geldenhuys and Oosthuizen (2015), who found weak school management support and teacher-related constraints to be significant obstacles to PD. Similar difficulties were also noted by Pham et al. (2024), who identified financial limitations, insufficient access to digital technologies, and unfavorable conditions, and by Tayag (2020), who also pointed out the pressure of work and the absence of funds as the main barriers to the professional growth of teachers.

In spite of its contributions, the survey should be viewed against a number of methodological limitations that could influence validity. The sampling was done among both public and private primary school teachers, but only those who were available and willing to fill in the questionnaire were sampled. This brings about the risk of self-selection bias, where teachers with more workloads, less institutional support, or more professional restrictions, which are some of the factors found in the survey as obstacles to PD, might have been less inclined to take part. It should be noted that the APDDPSTQ was administered in only one local government area (Ilorin South), a practical decision that also constitutes a methodological constraint. When an instrument is administered in a relatively homogeneous setting, it may not demonstrate sensitivity to change across different PD settings.

Pedagogical Implications

The results of this study have implications for educational practice, school leadership and policy formulation in Nigeria and other low- and middle-income countries. The discrepancy between the number of PD opportunities available and teachers' participation in PD indicates that more PD is not enough. Financial, workload and release time are all structural barriers that need to be overcome to promote meaningful engagement. Supportive policies and incentives, such as transportation allowances or PD time allocations, can enhance participation at school.

The results also underscore the importance of providing more digital literacy support in online PD programs. Digital skills proved to be a key barrier, so it is important to include basic technology training in programme design to make it accessible for teachers in under-resourced settings. In addition, the high score for limited recognition and promotion opportunities suggests that career advancement systems may not be sufficiently designed to recognize professional learning. Connecting the PD to promotion requirements may help to reinforce teachers' motivation to engage in ongoing development.

Future Directions

Future studies should administer the survey in more diverse settings, including rural and urban schools, or schools in different states with varying PD policy conditions, to further test whether the tool is capable of measuring the full spectrum of variation in teacher access, participation, and barriers to PD. These would enhance the construct validity of the instrument

and increase its applicability beyond the Kwara State. Qualitative study could also be applied to future research to capture the lived experiences and personal narratives of participants that closed-survey items are not able to fully represent.

INTERTEXTUALITY AS LEARNING IN TEACHER STORIES AND REPRESENTATIONS OF PRACTICE

Taylor Topham
Northwestern University
taylortopham@u.northwestern.edu

This paper examines teachers' naturalistic storytelling as a representation of practice in a professional development program for early career secondary mathematics teachers. It argues that storytelling reveals the intertextual nature of learning from representations of practice. The paper draws on an analysis of 48 episodes of teacher talk and presents a microanalysis of one episode. The analysis reveals how teachers narrated accounts of practice based on different evidence sources to support learning that the participants marked as valuable. The paper concludes that intertextuality is a valuable concept for future analysis of representations of practice more generally and storytelling in particular.

Keywords: Professional Development

Introduction and Purpose

There remain significant questions about the value of teachers' conversational stories as representations of practice to support teacher learning (Little, 2003; Pulvermacher & Lefstein, 2016; Segal, 2019). Teachers often rely on stories and narrated accounts to communicate about practice when other representations, such as video or student work, are inadequate or unavailable (Hall & Horn, 2012; Horn, 2010; Topham, 2024). However, narrative is understudied in mathematics education in general (Cannon & Dubbs, 2024) and recent studies of teachers' conversational stories have found mixed value for storytelling. For example, while Mendler and Vedder-Wiess (2023) found that video recordings and teacher stories could both lead to productive engagement, Segal's (2019) study of story exchanges found that teachers' sharing of stories could let teachers avoid the work of argumentation and reasoning about teaching practice, meaning storytelling could undermine learning in some cases.

To explore how teachers' storytelling can lead to learning, this study treats teachers' stories as "small stories" (Bamberg & Georgakopoulou, 2008), following Segal's (2019, p. 4) definition of a story as "a recounting of a past or hypothetical event as unfolding action, with an element of specificity (regarding time, place, and/or actors, or including a replay of enacted or imagined speech)." When applied to teacher talk, these stories include similar narrated accounts, such as what Horn (2010) called "replays" and "rehearsals."

Moving beyond Segal's framing of "story exchange," I treat teacher learning from stories as a form of intertextuality (Bloome et al., 2022; Hodges, 2015; Lemke, 1992). Intertextuality is the recognition that "we can make meanings through the relations between two texts; meanings that cannot be made within any single text" (Lemke, 1992, p. 257). Thus, teachers learn through story when they move beyond exchanging individual stories and toward connecting and synthesizing various perspectives on teaching practice represented in different stories. I ask: how do teachers use small stories, including re-narrations of other representations of practice, to achieve an intertextual understanding of teaching practice?

Data Sources and Methods

I draw on video recordings from a two-year professional development program that enrolled early-career secondary mathematics teachers from across the United States, analyzing data from

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

one cohort's (22 teachers) time in the program from 2017-2019. The analysis focuses on the program's small group coaching sessions carried out over a videoconferencing platform during each school year. A mathematics coach facilitated the small group sessions. Each group met three times per year for about 90 minutes and consisted of the coach plus three or four teachers. Most of the meeting time focused on discussing video clips from each teacher's classroom which everyone had previously viewed and annotated on a shared platform.

My analysis covers a sample of three small group meetings from the teachers' first year in the program. The sampled meetings are from three different time points during the year, and each contains different participants. There are ten teachers in the sample, plus the coach. I ultimately analyzed 5 hours and 16 minutes of video data.

To carry out this study, I first identified all the stories in the meetings (n = 116), then identified the larger conversational episodes (n = 48) surrounding the stories, bounding the episodes based on natural conversational shifts (Horn, 2005), with most episodes including more than one story. To analyze this data, I used methods from conversation analysis (Jordan & Henderson, 1995; Pomerantz & Fehr, 2011) and a recursive coding process (Charmaz, 2014; Corbin & Strauss, 1990; Saldaña, 2016) to identify how stories achieved social action and led to intertextual understandings. In this paper, I present a brief overview of some findings and a microanalysis of one episode of talk.

Findings

Similar to Segal (2019), I found that stories were often clustered in episodes, with several stories often occurring close together and spaces of time with no stories. The mean episode was two minutes and 45 seconds long and contained about 2.5 stories. 19/48 episodes contained three or more stories. My qualitative analysis revealed that the various stories in these episodes often synthesized preceding arguments, added new evidence, and identified connections with other stories or representations. This building of intertextuality often continued until one or more members of the group signaled that some form of valuable learning had been reached.

To answer my research question of *how* this played out across a conversation, I present and analyze an extended excerpt from a conversation where one small group was discussing a video shared by a teacher named Wesley (all names are pseudonyms). The group included Garima, the coach and facilitator, and Wesley, Jesse and Amit, who were all teachers. The episode started with Garima, the facilitator, prompting Wesley to share a question for discussion. After Garima's prompt, Wesley told the first story in the episode by recounting his experience planning the video-recorded lesson while hoping to see specific responses from students to show understanding. Wesley asked if he should keep hoping to see specific ideas and words from students or be more open and accepting of however students phrased their ideas. Jesse then initiated the group's discussion:

(1) Jesse: Yes, I'd love to comment on that or I think it's related to what you're getting at, where I felt like students [in the video] kept saying remainder theorem and factor theorem but I wasn't sure. […] They're not emphasizing it because they're like, "Oh, we learned this thing called remainder theorem so it's related to remainder theorem." They know that it's related to the problem. […] I would've loved to hear them take that extra step somehow and go from like, "Oh, this is related to factor theorem because if it's equal to zero, it's a factor." That's what you're looking for in terms of the explanation but then I'm

wondering if students are just thinking their reasoning is good enough, if they say, “Well, remainder theorem.” Right?

(2) Wesley: Right. You're saying, I should probably be more intentional in making sure that their explanations include their more reasoning than citing the said the said theorem, about why it works or why I would use this particular theorem on this particular problem rather than this is what we’ve been working on. Is that what you’re saying or?

(3) Jesse: Well, I guess I guess I’m not sure because you said you were looking for something really specific, right? I’m curious about what would be surfaced if you asked them, “Well, what does the remainder theorem help us do here, or why is it that this is appropriate in this?” because they’re citing it. They clearly know it. I have the exact opposite problem in my classroom, where if I taught them something like remainder theorem and then was like, “What are we using?” they’d just be like, “I don’t know. It’s equal to zero. We just know it’s supposed to equal zero.” […]

(4) Wesley: All right. That makes sense. Advice?

In his response (1), Jesse told the second story in this episode, creating an intertextual connection by re-narrating some of the details of Wesley’s story and drawing on other details from the video. Wesley then used this connection to draw implications for his practice (2).

Then, Jesse used another story to both downplay specific assertions about Wesley’s teaching and provide more evidence (3). This new intertextual connection gave insights from a story about Jesse’s own class (3). Wesley’s next turn (4) acknowledged the value of this new story but also indicated a need for more “advice.” The interaction continued:

(5) Garima: Amit, what are you thinking about?

(6) Amit: I’m thinking about how [in the video] you asked the closing question at the end because you were like, “Exit ticket.” [chuckles]

(7) Wesley: I had a real problem I wanted to solve. I saw that clock and it was over with.

(8) All: [Laughter]

(9) Amit: Again, all of our classes.

(10) Jesse: Every one.

(11) Amit: Every single one. So, I’m wondering if the exit ticket question could be something like what you're saying, Jesse, something along the lines of, let’s say, somebody were absent today. How would you explain to them that this problem was solved by remainder theorem? How would you draw that connection for a person who wasn’t here for our discussion? Clearly, we all know what we’re talking about. Can you make the connection for a third-party kind of thing, I guess. That’s the first thought that came to my mind because it's something you already used was this verbal exit ticket. I don't know how quick of an answer that would be, though, is the only thing. Under time, I feel like kids would probably take some time to think about that question. I don’t know how quick that could go, but maybe it could be an entrance ticket for another day, I don’t know.

(12) Garima: I think that would give you some interesting formative assessment data around when you say, “Why did we use it?” do kids end up giving a response that tells you how they used it, or that makes that conceptual connection that you’re really looking for. I think kids often get explanation or narration of process

rather than justification, and they're not sure where the line is. I think that's something we have to help define for them of what's a sufficient explanation.

(13) Amit: That's a good point. Can you write that down, Garima?

(14) Wesley: That was pretty dope.

After Garima's invitation (5), Amit re-narrated further details from the video (6), thus introducing another story to the conversation. At this point, Wesley jumped in (7) to provide details not available in the video by narrating his thought process in the moment. The group laughed (8), and Amit and Jesse's comments (9, 10) signaled that the laughter arose because running out of time had previously been a topic of conversation. As the laughter subsided, Amit presented an idea for how to use the exit ticket approach to generate student comments and provide Wesley with a more detailed sense of his students' understanding, explicitly connecting his own idea with Jesse's previous thoughts (11). However, after presenting this idea, Amit also hedged it by bringing back up the idea of running out of time (11). After this hedge, Garima re-entered the conversation to support Amit's suggestion and then connected it back to Jesse's original thoughts (1) about students not explaining enough, reinforcing the intertextual connections present in the conversation. After Garima's turn, in contrast to the original response to Jesse's ideas (4), both Amit and Wesley marked Garima's final summation as a "good point" (13) and "pretty dope" (14), suggesting that the group had gained some new insights.

Significance

The analysis of this excerpt reveals a fascinating trajectory of teachers' learning through storytelling. Stories told by Wesley, Jesse, and Amit drew on different sources to create intertextual connections that supported the group in grappling with practice. The lens of intertextuality reveals how teachers learn as they move beyond exchanging individual stories to building connections between them. Specifically, this analysis reveals how contrasting stories, such as the story Jesse told about his own classroom (3), are not necessarily in conflict with each other but can come together to produce a nuanced understanding of teaching practice based on multiple perspectives. This does not mean that stories will always produce valuable intertextual perspectives or that they cannot devolve into conflict. However, recognizing these intertextual connections for what they are can provide valuable tools for analyzing teachers' use of stories to support their learning.

This study is limited in scope by focusing on one small conversation and not attending explicitly to questions of power, such as the position of Garima as the coach and how it affects the reactions to her contributions to the conversation (especially turn 12). However, this paper still has implications for the study of teachers' use of representations of practice more generally and suggests important lines of future research. Recognizing teachers' naturalistic stories as representations of practice means recognizing that teachers are constantly representing practice in different ways and for different ends in their talk. To do this, teachers draw on their own experiences and other available representations, such as video in this case. Future research could examine the different ways teachers' stories draw on, enhance, or contradict other representations to identify specific types of storytelling that are valuable for learning, recognizing that drawing material from another representation of practice is a form of intertextuality. Indeed, it is possible that narrating actual and possible classroom events is necessary for teachers to connect representations of practice to their own experiences (see Oliver et al., 2018). If this is the case, designers, facilitators, and teacher educators should take teachers' storytelling seriously as a form of learning and find ways to support teachers in making

intertextual connections as they tell stories. This could mean inviting teachers to share experiences as stories but also finding ways to invite accounts that synthesize disparate perspectives to narrate new practices.

This study examines how professional development can support teachers in advancing students' graph literacy through real-world graphs. We conducted an online workshop with 20 middle and high school mathematics and science teachers focused on using news and media graphs in instruction. Teachers selected graphs from a New York Times resource and generated questions for classroom discussion. We found that most questions emphasized mathematical features (e.g., trends and comparisons), with limited attention to contextual and critical dimensions. In response, we propose a research-informed questioning framework and discuss implications for professional development and teacher education.

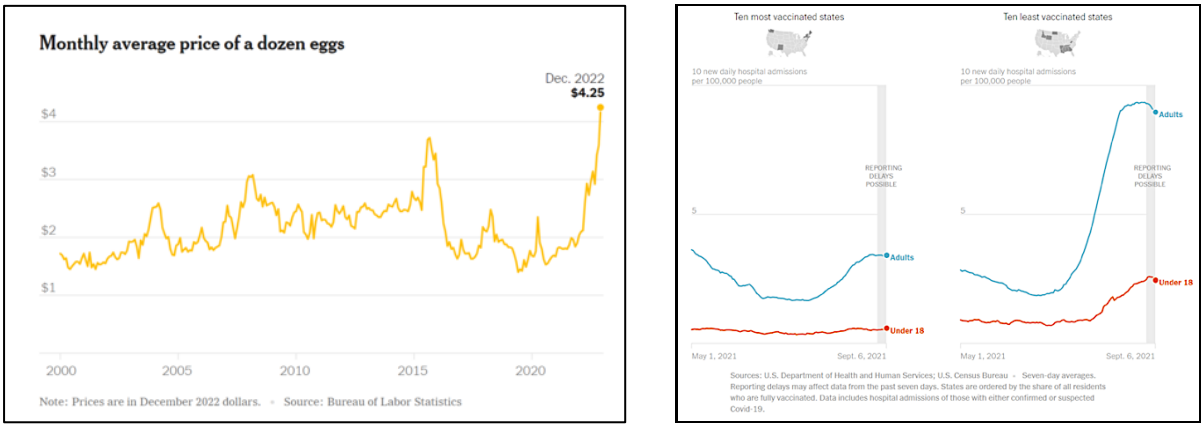
Keywords: Professional Development, Graph Literacy, In-Service Teacher Education

We live in a data-driven world where graphs appear daily in news, social media, and public reports. As consumers of information presented in graphical form, individuals must develop graph comprehension—the ability to derive meaning from graphs created by others—and engage in making sense of quantitative information represented visually (Friel et al., 2001). This involves not only reading values and trends but also interpreting how information is structured and communicated through the graph. To navigate these responsibly, one must be able to read, evaluate, and make informed decisions based on the data presented (Weiland, 2017). Students, therefore, need experience interpreting real-world media graphs. In contrast, graphs encountered in school mathematics classrooms often appear in decontextualized forms and emphasize standard structural features, such as clearly labeled axes, axes intersecting at (0, 0), and uniform scales (Paoletti et al., 2022; Weiland, 2017). This difference may leave students underprepared to interpret the graphs they encounter outside of school-one needs to be graph literate.

Theoretical Framework

So, what does it mean to be graph literate? Curcio (1987) proposed a framework of reading the data, reading between the data and reading beyond the data that measures students' ability to extract information, identify pattern, and making predictions from a given graph. This framework guides educators to design tasks that deepen students' graph comprehension (Friel et al., 2001). Shaughnessy (2007) later introduced a fourth category: reading behind the data, which emphasizes examining the causes of variation and making connections between the data's context and its graphical representation. However, students encounter graphs not only in textbooks but also in media and public discourse. Gal (2002) and Watson (1997, 2003) argue that statistical literacy involves understanding statistical information in social and media contexts and questioning claims made in contexts that lack proper justification.

Drawing on scholarship in critical mathematics education, Weiland (2017) defines critical statistical literacy as the ability to interpret, interrogate, and evaluate statistical arguments, particularly in relation to issues of bias, power, equity, and how data shape social structures. Bailey and McCulloch (2023) extend this perspective by articulating what such engagement looks like in practice through critical statistical literacy habits of mind, drawing on Lee and Tran's (2015) work on statistical habits of mind. Together, this body of research suggests that



graph literacy requires both mathematical interpretation and critical contextual evaluation. In this paper, we conceptualize graph literacy as comprising two interconnected dimensions: (1) mathematical and statistical analysis of patterns, relationships, and inferences within a graph; and (2) critical contextual analysis of data sources, representation, and social implications. This conceptualization informs the questioning framework introduced in our workshop.

Methods and Session Overview

We conducted a two-hour online workshop for 20 in-service middle and high school mathematics and science teachers from schools in a large Northeastern U.S. city. Of the 20 participants, 15 taught high school and five taught middle school; there were 13 mathematics teachers and seven science teachers. Their teaching experience varied, with 70% having 8–15 years of teaching experience, 20% with more than 16 years, and 10% with 4–7 years of experience. We designed the workshop to support teachers in using real-world graphs to strengthen students' graphical reasoning and develop their skills to critically evaluate the contexts represented in the graphs.

Preliminary Results

We administered a pre-session survey (n =13) in which teachers reported how and why they use graphs in their classrooms and wrote questions for a sample graph from the NYT (Figure 1a). We opened the workshop by comparing and contrasting textbook graphs with real-world graphs from news and media sources. We then introduced the New York Times "What's Going on in This Graph?" resource (The Learning Network, n.d.). As a first Activity, teachers explored the site in break out rooms, selected a graph of their interest, and discussed how they might engage students in analyzing the graph if they were to use it in their classrooms. In Activity 2, we presented a graph (Figure 1b) and asked teachers to generate questions to guide classroom discussion. Here we describe the survey results and observations from the two activities.

(a) (b)

Figure 1: Graphs from NYT (The Learning Network, n.d.) – (a) Monthly Average Price of a Dozen Eggs, (b) Rate of Covid Hospitalizations in the U.S.

Pre-Session Survey Results

The pre-session survey examined teachers' instructional goals, classroom practices, and use of real-world graphs. Responses revealed a tension between teachers' stated goals and their teaching practices. Many participants described connecting mathematics to real-world issues and

encouraging discussion as important goals when teaching graphs. Yet several reported rarely using real-world or media-based graphs in their classrooms. Teachers reported several challenges such the "messier" nature of real-world data, noting that "many graphs students deal with *have* to be exact—perfectly linear, perfectly quadratic—and the real world is not like that." One teacher wrote when using graphs from real world contexts "I sometimes also struggle to come up with interesting questions for students to ponder as they examine these graphs." Several teachers described difficulties related to context and questioning, including "lacking background knowledge to make graphs relevant."

When asked to generate questions for a graph on monthly average price of a dozen eggs in the US in 2022 (Figure 1a), most participants focused on mathematical features (e.g., "During which month was the price highest?", "What is the average rate of change between January and March?", "Is the trend increasing or decreasing?"). Only a few questions were on contextual factors (e.g., "Why do you think this graph was created?", "What argument or claim can you make with this graph?"). Together, these responses suggest that while teachers value real-world engagement, they may need support in framing questions that move beyond mathematical interpretation toward contextual analysis.

Observations from Activity 1

In Activity 1, teachers explored the NYT graph website (The Learning Network, n.d.). The purpose was to introduce them to graphs based from media on real and current issues and to think about whether and how they might use such graphs in their classrooms. Teachers selected graphs on topics such as food and health, U.S. imports from China, air pollution, time use during the pandemic, and electric vehicle adoption. These graphs looked different from typical textbook graphs by using colored images, complex layouts, multiple variables, and artistic non-linear layouts to highlight trends in real-world data. Teachers noted that the graphs were different from the traditional textbook graphs but were timely and could lead to discussion. Nevertheless, most groups focused on why the graph was interesting rather than on the kinds of questions they would ask students to prompt thinking about the context in the graph.

Observations from Activity 2

To move from exploration to structured questioning, in Activity 2, we asked teachers to generate questions for a graph on Covid hospital admissions in the most and least vaccinated states (Figure 1b). Specifically, we asked teachers to distinguish between questions that support mathematical reasoning and questions that invite real-world discussion. Across all groups, teachers produced numerous mathematical questions. These focused on identifying variables, interpreting rates per 100,000, determining intervals of increase and decrease, considering function type or best fit, explaining slopes and trends, and determining the rate of change.

In contrast, contextual questions were more limited. Teachers from two groups generated a few reflective questions. For example: "What message is this trying to send?", "Who's recording/sharing this data?", "What feelings might this evoke in people?", and "How might interpretation change if only one graph were shown?" Other groups wrote as few as one or two broad prompts (e.g., "COVID-19 era"), and one group did not generate any contextual questions. During whole group discussion, several participants noted that they had not previously separated mathematical and contextual questioning in this way and that generating such questions required more deliberate thinking. This pattern suggests that while teachers are comfortable framing mathematical questions, they may need clearer structure or sample prompts to help them write questions that guide students to think about the context.

A Framework for Structuring Classroom Discussions

After participants completed both the activities, we introduced our graph literacy framework for structuring a classroom discussion (Figure 2). The framework operationalizes the two dimensions described in the theory section—mathematical/statistical analysis and critical contextual analysis—and translates them into concrete question types that teachers can use in the classroom. It was presented as a practical tool to help teachers move more intentionally between analyzing patterns in a graph and examining its context, source, and implications.

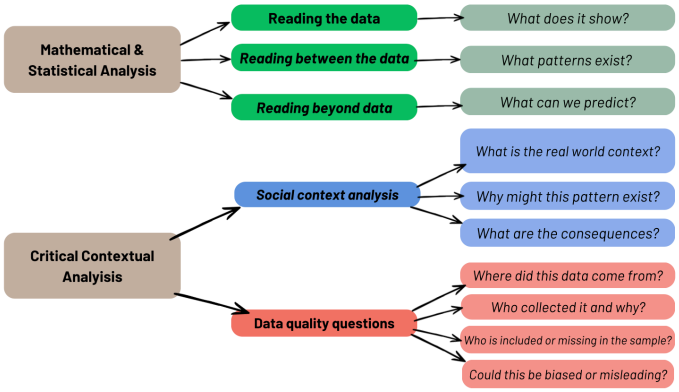


Figure 2: A Framework for Structuring Classroom Discussions

After introducing the framework, we modeled how it could be used in practice by providing sample questions for the Covid admissions graph. For example, teachers might ask: What was the approximate hospitalization rate for adults in the least vaccinated states in early September 2021? (reading the data); How do hospitalization rates compare between the most and least vaccinated states? (reading between the data); What might happen to hospitalizations if vaccination rates increased? (reading beyond the data); Where did this data come from, and how are "most" and "least" vaccinated states defined? (data quality); or why might rates differ between these states, and who is most affected? (context and impact). These examples show how teachers can move from trends to context and consequences.

Preliminary Discussion and Implications

This study examined how in-service teachers generated questions around socially situated graphs drawn from NYT and introduced a questioning framework to support graph literacy. Participants described the framework as useful and practical, and several indicated that they would try using it in their classrooms. While teachers readily generated mathematical questions about trends, slopes, and comparisons in the given graph, few framed questions about its context, construction, or implications. Teachers noted that this type of questioning required deliberate effort and was not part of their usual practice. Our observations echo prior research highlighting the need for professional development and curricular support (Watson & Callingham, 2003; Weiland, 2017) for teachers to assist their students in developing graph literacy. Preservice preparation, professional development, and curriculum materials that include socially situated graphs with modeled questioning strategies may better support teachers in engaging students in both mathematical analysis and critical contextual evaluation. In an era where students regularly encounter graphs in news outlets and social media, the ability to question how data are selected, categorized, and framed is central to graph literacy. This study contributes a practical, research-informed questioning framework that translates theoretical dimensions of graph literacy into

classroom-ready prompts. By modeling how teachers can move from identifying trends to examining context and implications, the framework offers a structured approach to integrating critical graph analysis into everyday instruction.

This study investigates the algebra knowledge of 153 in-service mathematics teachers at the senior high school level in Ghana using the Knowledge of Algebra for Teaching (KAT) framework. Utilizing a cross-sectional survey design across 40 schools, the study assessed teachers through a 74-item achievement test. Results reveal a significant discrepancy between procedural fluency and conceptual depth: while 83% of teachers correctly ordered the derivation of the quadratic formula, 79.1% failed to solve a basic algebraic rate problem, and 56.9% could not identify correct pedagogical explanations for student misconceptions. The findings indicate that while "School Knowledge" is relatively high, specialized "Teaching Knowledge" and "Advanced Knowledge" remain underdeveloped. The study advocates for a shift in teacher training toward the multidimensional knowledge types identified in the KAT framework.

Keywords: Algebra and Algebraic Thinking, High School Education, Teacher Knowledge, Advanced Mathematical Thinking

Background

Algebra is positioned as a foundational strand of school mathematics, with standards discourse emphasizing reasoning, representation, and conceptual understanding rather than procedural reproduction alone (National Council of Teachers of Mathematics [NCTM], 2000). Research on teacher knowledge has long argued that teaching quality depends on more than subject matter competence; it also depends on specialized knowledge that supports explaining ideas, anticipating learner thinking, and selecting representations (Shulman, 1986). Subsequent work has elaborated how effective instruction involves interweaving content and pedagogy in ways that sustain mathematical integrity while making ideas learnable (Ball & Bass, 2000), which is especially consequential in algebra where teachers must manage both symbolic procedures and conceptual structure (Ferrini-Mundy et al., 2005). Internationally, questions of alignment between classroom practice and standards expectations remain persistent (Jacobs et al., 2006), reinforcing the relevance of professional development that targets teachers' knowledge and its instructional enactment (Mewborn, 2003). In the Ghanaian context, earlier doctoral work provides local evidence that teachers' algebra-for-teaching knowledge relates to student performance, motivating renewed attention to the profile of knowledge domains required for instruction (Wilmot, 2008).

Objectives and Purposes of the Study

Algebra is positioned as a foundational strand of school mathematics, with global standards emphasizing reasoning, representation, and conceptual understanding over procedural

reproduction (NCTM, 2000). In the Ghanaian context, earlier evidence suggests that teachers' algebra-for-teaching knowledge is a significant predictor of student performance, motivating renewed attention to the profile of knowledge domains required for effective instruction (Wilmot, 2008).

Despite its importance, Ghanaian students have historically underperformed on international assessments such as the TIMSS in 2003, 2007, and 2011 (Wilmot, 2008). Chief Examiners for the West African Examination Council (WAEC) frequently cite students' inability to perform algebraic tasks, yet it remains unclear if these difficulties stem from student-level deficiencies or a lack of conceptual depth in the teachers' own knowledge (Wilmot, 2008). This study investigates the algebra knowledge possessed by in-service mathematics teachers at the Senior High School (SHS) level within the Knowledge of Algebra for Teaching (KAT) framework. Specifically, it addresses:

1. The overall proficiency level of SHS mathematics teachers in algebra based on the KAT framework.
2. The extent to which the boundaries between the three knowledge types (School, Advanced, and Teaching) are sustained or overlapping.
3. The alignment between teacher knowledge and the conceptual demands of the Ghanaian curriculum.

This research addresses the PME-NA 2026 theme, "Changing Mathematics Education by Educating for Change," by identifying where teacher training must evolve to move beyond procedural stagnation and provide equitable learning experiences (PME-NA, 2026).

Perspective and Theoretical Framework

The theoretical foundation of this study is the KAT framework, which re-conceptualizes Shulman's (1986) notions of content knowledge and pedagogical content knowledge specifically for school algebra. Subsequent elaborations have emphasized that effective instruction involves interweaving content and pedagogy to maintain mathematical integrity while making ideas learnable (Ball & Bass, 2000). The framework posits three intertwined domains:

1. *School Knowledge:* Mastery of the intended K-12 mathematics curriculum (NCTM, 2000; Wilmot, 2008).
2. *Advanced Knowledge:* College-level mathematical perspective (e.g., Abstract Algebra, Calculus) that provides a trajectory for mathematical ideas (Ferrini-Mundy et al., 2005).
3. *Teaching Knowledge:* Specialized mathematical insights used to identify student misconceptions and select appropriate algebraic tasks (Ferrini-Mundy et al., 2005).

Recent literature has expanded this by introducing the Technological Knowledge of Algebra for Teaching (T-KAT) framework, arguing that modern instruction requires teachers to integrate digital tools to unpack complex concepts (Osei, 2024; Osei & Agyei, 2024). Furthermore, contemporary work on Pedagogical Content Knowledge (PCK) highlights the necessity of understanding how students conceptualize specific topics to apply strategies that enhance deep learning (Li & Copur-Gencturk, 2024).

Methods and Modes of Inquiry

This study utilized a cross-sectional survey design to capture a snapshot of teacher knowledge (Wilmot, 2008).

Participants and Sampling

The target population included SHS mathematics teachers in the Ashanti, Western, and Central Regions of Ghana. A multi-stage sampling technique categorized schools (A, B, C, D) per Ghana Education Service (GES) classification. From 40 randomly selected schools (10 single-sex, 30 co-educational), a final sample of 153 in-service teachers currently teaching core or elective mathematics was achieved.

Data Collection and Analysis

The instrument was a 74-item multiple-choice achievement test adapted from the KAT project and contextualized for the Ghanaian academic environment (Wilmot, 2008). Items were revised to reflect local currency (Cedis) and market commodities to ensure context validity. Reliability was established with a KR-20 coefficient of 0.855. Data were analyzed using descriptive statistics and Analysis of Variance (ANOVA) to compare performance across the three KAT domains.

Results

The analysis reveals a profile characterized by high procedural fluency but notable conceptual and pedagogical gaps.

Domain-Specific Performance

Teachers demonstrated appreciable competence in School Knowledge (M = 1.0688, SD = 0.1900), significantly outperforming their levels of Advanced Knowledge (M = 0.3159, SD = 0.1780) and Teaching Knowledge (M = 0.2369, SD = 0.1623), which were comparatively low.

Procedural Fluency against Conceptual Application

Standard procedural tasks showed high proficiency; 83% of teachers correctly identified the steps to derive the quadratic formula. This is attributed to the fact that 72% of the participants have a formal education background where such derivations are heavily emphasized (Wilmot, 2008). However, conceptual application was weak. On Item 27, which required solving an algebraic rate problem involving two pipes filling a tank, 79.1% (121 out of 153) of teachers answered incorrectly, often failing to realize that two pipes working together must take less time than the fastest individual pipe (Wilmot, 2008).

Pedagogical Content Knowledge and Misconceptions

Regarding student misconceptions (Item 39), 56.9% of teachers were unable to correctly explain why dividing both sides of an equation by a variable (e.g., $2x^2 = 6x$ by x) is problematic. Many selected incorrect justifications or could not identify the risk of losing the solution $x = 0$, indicating a lack of the specialized "Teaching Knowledge" required to navigate student errors while maintaining mathematical integrity (Ferrini-Mundy et al., 2005; Wilmot, 2008).

Discussion and Conclusions

The findings suggest that the knowledge base of SHS teachers in Ghana is "thin" and predominantly curriculum-bound, supporting earlier claims that subject matter competence alone is insufficient for reform-oriented teaching (Shulman, 1986; Wilmot, 2008). The high procedural success vs. conceptual failure on rate problems mirrors international concerns regarding the alignment between classroom practice and standard-based expectations (Jacobs et al., 2006).

Educating for Change

In alignment with the "Educating for Change" theme, this study highlights that current systems produce teachers who are procedurally competent but conceptually limited, which

perpetuates mathematics as a gatekeeper (PME-NA, 2026). If teachers cannot conceptually "unzip" content, they cannot address the systemic injustices that exclude learners from advanced STEM trajectories. Current research emphasizes that teachers need knowledge of mathematical problem-solving not just for themselves, but as a broader pedagogical skill to help students become resilient problem solvers (Lit et al., 2026; Schreiber, 2025).

Synthesis and Recommendations

The study concludes that the boundaries between knowledge types are indeed fuzzy and overlapping, with weaknesses in one domain (Advanced Knowledge) directly limiting effectiveness in another (Teaching Knowledge).

1. *Curricular Reform:* Training institutions should develop courses helping teachers explore all seven knowledge types required for algebra, including functional thinking (Twohill et al., 2025).
2. *PCK Focus:* Professional development must shift from "what" to teach to "how" students conceptualize topics, using representations that enhance learning (Li & Copur-Gencturk, 2024).
3. *National Restructuring:* Findings should inform the restructuring of university mathematics programs and the integrated mathematics curriculum in Ghana to prioritize conceptual application over memorization (Wilmot, 2008).

Acknowledgements

We appreciate the efforts put in by all In-service mathematics teachers before, during and after the study.

DO RACE AND GENDER MATTER?: TEACHER LEADER RESPONSES TO MICROAGGRESSIONS

Microaggressions convey negative attitudes toward people from nondominant groups (Nadal et al., 2014; Sue et al., 2007) and are subtle, common occurrences that can be intentional or unintentional. We investigated, "How do developing STEM teacher leaders respond to a hypothetically observed teacher-to-student microaggression?" The focus of this study is a cohort of nine teacher leaders (TLs) in a five-year professional development (PD) fellowship aimed at further developing their leadership. As part of the PD, the TLs participated in five experiences: coaching on the topic of Professional Noticing (Jacobs et al., 2010), equitable teaching practices for urban schools (Johnson et al., 2019), engaging in a university laboratory setting, apprenticing as instructor in a methods class, and a STEM Education Leadership EdD.

Methodology

The participants were seven mathematics and two science teachers who teach grades ranging from elementary to high school; all taught at urban schools in high needs districts. Six identify as women and three identify as men and the TLs come from a mix of cultural backgrounds. We conducted semi-structured interviews in which the teacher leaders were presented with two scenarios. In one scenario we asked TLs if and about how they would respond to a colleague's remark about a student of a particular background. We followed this task by asking about how their response might change based on the race and/or gender of the teacher and student, which allowed us to capture variation in their perceptions (Leyva et al., 2021). The interviews were coded and organized into emergent themes through axial coding (Creswell, 2013).

Results and Discussion

Many TLs considered their own backgrounds (e.g., queer, Jewish) in giving the teacher in the scenarios the benefit of the doubt or in choosing when to respond. Coding categories included: Responses, Considerations for Response, Motivation to Respond, and Strategies for Response. Under Responses, for example, in the theme of *Clarifying Question*, were codes that distinguished a presumed intent: C1-Curiosity about Meaning, C2-Reflecting a mirror to the speaker, and C3-Making sure the TL heard correctly. Although most of the TLs described similar responses, their reasoning differed when asked about race and gender. One TL centered their differing backgrounds while acknowledging she may not possess the lived experiences that situate the exchange, thus rooting her response in developing understanding. In contrast, many TLs expressed that racial/gender background doesn't matter because the microaggression was harmful regardless of the backgrounds of either party. The research helps us understand how TLs center their own and others' identities when thinking about how to respond to microaggressions.

Spatial thinking—the ability to generate, manipulate, and reason about spatial relations between and within objects—is both highly malleable and strongly associated with mathematics performance (Hawes et al., 2022). Yet, spatial reasoning activities remain largely absent from typical mathematics instruction. To address this, we engaged in a research-practice partnership with grades 5-12 teachers at a New Brunswick school, partnering with 16 teachers to co-develop a curated collection of learning activities to support the implementation of spatialized approaches in their classrooms. Professional learning began with a two-day in-person intensive and continues through monthly sessions delivered both in person and virtually. Teachers expressed strong enthusiasm for the project during the initial intensive but also reported frustration with the lack of ready-to-implement spatialized lessons. In response, we adjusted our approach shifting from broader research dissemination to developing a collection of classroom-ready materials to support implementation and modeling concrete strategies for spatialization within existing curricula. Here, we share preliminary reflections derived from both qualitative analysis of pre and post teacher survey data as well as qualitative narrative and thematic analysis of teacher-researcher discussions and shared classroom artefacts as a proxy for implementation. These analyses point to increased teacher understanding of spatial thinking concepts as well as iterative refinement to classroom implementation of spatial approaches over the course of the year. Further, additional analyses of teacher reflections point to the promise of collaborative design as an effective tool for professional learning (Voogt et al., 2015).

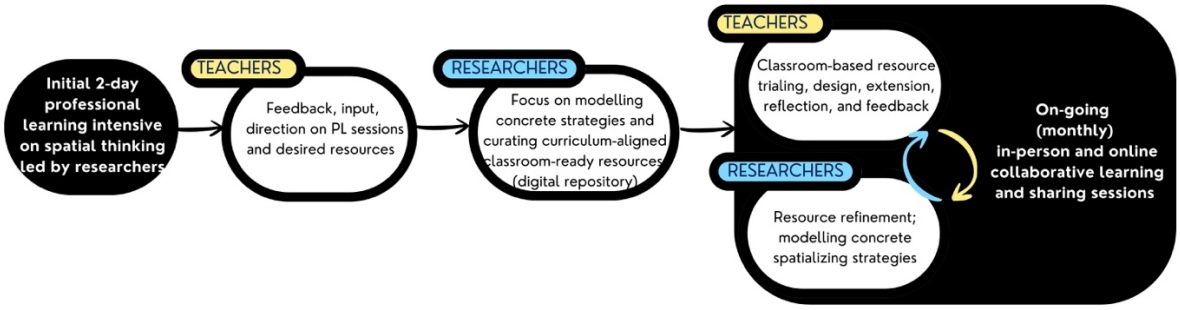

Figure 1: Design-research Approach for Professional Learning, Showcasing the Use of Reflections, Surveys, and Artifacts in Assessing Implementation Cycles.

This design-research (Figure 1) is part of a larger study investigating how integrating spatialized activities into middle- and high-school mathematics and science classrooms can

support student learning and performance, and how teachers adopt and adapt such practices. As analyses of teacher and student learning data continue, this work aims to contribute empirical insight into how spatial reasoning can be meaningfully integrated into middle school and secondary mathematics instruction and how such integration may influence student outcomes.

DESIGNING PROFESSIONAL LEARNING FOR MATHEMATICS TEACHER LEADERS: EVIDENCE-BASED FACILITATION OF JOB-EMBEDDED PROFESSIONAL LEARNING

Deena Soffer Goldstein
University of Illinois at Chicago
deoffe2@uic.edu

Fati Alipour
University of Illinois at Chicago
falipo2@uic.edu

Keywords: Professional Development

Teacher learning is central to instructional improvement in mathematics, and job-embedded professional learning is increasingly recognized as a sustainable context for supporting that learning (Darling-Hammond et al., 2017). However, research indicates that discourse within these settings is often anecdotal and insufficiently grounded in evidence, limiting opportunities for meaningful professional learning (Horn & Kane, 2015; Lefstein & Perret-Clermont, 2014).

The Learning to Lead in Math (LTL-M) Project is designed to address this limitation by developing mathematics teacher leaders' (MTLs') capacity to facilitate evidence-based, student-centered discussions in job-embedded professional learning contexts. Central to the design of the project are active teacher learning routines in which MTLs engage with evidence from practice and develop the capacity to facilitate teacher learning that is grounded in evidence about instruction, student thinking, and mathematics learning (Darling-Hammond et al., 2017; Ball & Cohen, 1999).

As part of LTL-M, MTLs participate in professional learning focused on facilitating active teacher learning routines: analyzing instructional practice, analyzing student work, and lesson planning. These routines utilize classroom video, student work, and curricular materials. While these forms of evidence are frequently used in professional learning, they represent practice in different ways and therefore create different opportunities and challenges for facilitation (Grossman et al., 2009; Borko et al., 2014). Little is known about how these different forms of evidence shape opportunities for teacher learning or the specific demands they place on MTLs as facilitators. Understanding the affordances and constraints of different forms of evidence is critical for designing professional learning that prepares MTLs to facilitate evidence-based discussions.

In this poster, we present a design-oriented analysis of how different forms of evidence function within these three active teacher learning routines. The different forms of evidence make particular aspects of practice visible, creating distinct opportunities for teacher learning while also requiring specialized mathematical knowledge for teaching (Ball et al., 2008) and facilitation knowledge (Borko, 2016; Grossman et al., 2009; Jacobs et al., 2010). Across these routines, we analyze evidence in terms of representation type (static or dynamic), affordances and constraints, and the associated knowledge demands for facilitation. The goal of this work is to inform the design of professional learning experiences that build MTLs' capacity to facilitate productive, evidence-based discussions in job-embedded professional learning contexts.

LEARNING TO NOTICE POSITIONING IN AN ONLINE ASYNCHRONOUS PROFESSIONAL DEVELOPMENT

Brent E. Jackson
WestEd
bjackso@wested.org

Erica Askew
WestEd
easkew@wested.org

Keywords: Professional Development, Teacher Noticing, Equity

Mathematics teachers need professional development (PD) throughout their careers to support their continued learning (Feiman-Nemser, 2001). High-quality PD can support teachers' mathematical knowledge for teaching (MKT; McDuffie et al., 2014) alongside the development of equitable teaching practices, such as positioning of students (Bartell et al., 2017). Unfortunately, high-quality PD is not easily accessible to many teachers (Nite & Bicer, 2020). Online asynchronous PD has the potential to remove cost and time barriers. In this poster, we present research related to an online asynchronous PD designed to support teachers to learn the equitable practice of positioning students as competent within the mathematical context of a transformations-based approach to linearity and similarity (Seago et al., 2013).

The Video in the Middle course engaged teachers in six modules (approximately 20 hours total) with each module focused on analyzing the positioning practices in one classroom. The central activities in each module consisted of teachers watching and analyzing classroom video with preloaded facilitator comments that highlighted (Goodwin, 1994; Grossman et al., 2009) and discussed important moments related to interpreting students' positions and storylines in classrooms. These activities took place within a purposeful sequence of 21 activities; although all activities were influential in supporting teachers' noticing skills, we do not fully describe them here due to space limitations. Overall, teachers watched and asynchronously discussed 10 different classroom videos. We designed these activities to cultivate teachers *professional vision* (Goodwin, 1994) related to the practice of positioning. The data we report here is from an initial noticing activity given to teachers prior to beginning the PD and a final noticing activity that utilized the same initial video as a part of the final module. In these activities we asked teachers to respond to the question, *What do you find noteworthy and why?*

We drew on van Es (2011) coding scheme to analyze teachers' depth of noticing. Level one included responses that primarily attended to the whole class environment and level two attended primarily to teacher pedagogy. Responses coded to level three attended to students' and/or teacher's actions; Level four responses attended to the relationship between students' and teachers' (interactions). All responses were double-coded by the authors and discrepancies were resolved through discussion until there was mutual agreement.

Preliminary results suggest that the PD did support teachers to notice at deeper levels. On the pre-PD noticing activity, six teachers' responses were coded as level one, seven as level two, and one as level four. In the final noticing activity, two teachers' responses were coded as level one, five as level two, five as level three, and two as level four. A majority (eight) of teachers' responses were deeper at the post-noticing activity, while four remained steady and two decreased. Although many teachers' depth of noticing increased throughout the PD, we also noticed that their reasoning was not supported by interpreting students' possible positions and classroom storylines. In this poster we discuss implications for the design of subsequent iterations of this online asynchronous PD.

AI-SUPPORTED PROFESSIONAL LEARNING OF PRESERVICE MATHEMATICS TEACHERS: IMPLICATIONS FOR SUPPORTING STUDENTS' ZONE OF PROXIMAL DEVELOPMENT

Ghan Shyam Joshi
Purdue University
joshi313@purdue.edu

Keywords: Mathematical Knowledge for Teaching, Professional Development, Teacher Educators, Technology

The rapid expansion of generative artificial intelligence (GenAI) has entered mathematics teacher preparation programs, where preservice teachers use tools that draft lessons, suggest solution paths, simulate student responses, and provide instructional feedback. Although AI's role in mathematics teacher professional development has received limited attention (Joshi & Heinold, 2025; Joshi, 2026), it is important to examine how AI-supported professional learning shapes preservice mathematics teachers' ability to support students' learning within the Zone of Proximal Development (ZPD). This review asks: How does AI-supported professional learning shape preservice mathematics teachers' capacity to design and enact instruction aligned with principles of the ZPD? Vygotsky's (1978) ZPD guided the analysis of this review.

A systematic literature review was conducted following PRISMA protocols (Page et al., 2021). Six databases were searched for peer-reviewed empirical studies on AI in preservice mathematics teacher education published from 2023 to January 2026. 178 records were identified, and only 13 studies met the inclusion criteria after duplicate removal and screening. Data were analyzed using reflexive thematic analysis (Braun & Clarke, 2006). This poster conference proceeding included the highlights of four representative studies (Bernardi et al., 2025; Flavin et al., 2025; Gurl et al., 2025; Son et al., 2024) that illustrate the three central themes identified across the review.

The first theme was that AI functioned as a mediational resource rather than an instructional authority. Preservice teachers used professional judgment to interpret AI outputs rather than treating them as authoritative. AI-supported simulations enabled responsive teaching practice through interactions with virtual students (Son et al., 2024), while GenAI broadened lesson-planning possibilities and promoted reflection on instructional alternatives (Bernardi et al., 2025; Gurl et al., 2025). The second theme highlighted how teacher knowledge shaped the quality of this mediation. Participants differed in how they questioned, revised, or accepted AI-generated outputs (Flavin et al., 2025). Those with stronger mathematical knowledge engaged more critically, whereas others were more likely to accept outputs uncritically, sometimes leading to errors in lesson plans. Studies also found that pedagogical outputs were evaluated more accurately than mathematical outputs (Gurl et al., 2025; Bernardi et al., 2025).

The third theme integrated these findings within the ZPD framework. Because the quality of AI mediation depended on teachers' mathematical and pedagogical knowledge, AI did not function as scaffolding independently. Instead, preservice teachers transformed AI outputs into meaningful scaffolds by evaluating, adapting, and orchestrating them in response to students' needs. In this sense, AI expanded opportunities for instructional support, but its contribution to student learning depended on informed teacher mediation.

AI rarely served as an instructional authority; rather, its contribution to instruction aligned with the ZPD depended on preservice teachers' ability to critically evaluate and adapt AI-

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

generated outputs (Flavin et al., 2025; Son et al., 2024). From a sociocultural perspective, AI functions as a mediational artifact within the ZPD (Vygotsky, 1978), whose value is realized through knowledgeable teacher mediation. This review is based on 13 empirical studies. Future research should examine how AI-supported teacher mediation contributes to students' mathematical learning within the ZPD.

Keywords: Teacher Education, Professional Development

Our poster aims to present the *Instructional Circle* (Melville, 2022) model and discuss its affordances and obstacles for mathematics teacher educator (MTE) professional learning. MTEs need an additional layer of expertise for working with prospective teachers, beyond the knowledge needed for K-12 teachers to work with students (Castro Superfine & Li, 2014a). Lave and Wenger (1991)'s community of practice offers a promising approach for supporting MTEs' professional development (Castro Superfine & Li, 2014b; Dick et al., 2022; Castro Superfine & Pitvorec, 2021; Olanoff et al., 2021). We propose instructional circles (Melville, 2022) as an innovative structure that leverages our community of practice to build MTEs' knowledge and skills for preparing mathematics teachers.

Instructional circles are a common professional learning opportunity in Japan, which helps teachers deprivitize their practice, address specific problems of practice, and meet their professional goals. Instructional circles are often made up of teachers with the support of math instructional coaches and/or university professors serving as a *knowledgeable other*. During an instructional circle, teachers present their research lesson that address a desired problem of practice (Takahashi, 2015). Other group members and the knowledgeable other then engage in feedback-giving practices towards improving the identified problem. Not only does the presenting teacher receive support, but the discussion could have implications for the other members' practice.

The instructional circle we started as university-based MTEs is a novel use of the model. Initially, our group needed support in teaching teacher education courses. Similar to K-12 instructional circles, each month we alternate presenting research lessons and problems of practice, giving feedback, and reflecting on our experiences. The novelty of the model for MTEs is that group members draw on each other's expertise because there is no knowledgeable other to guide the conversation or provide insight into theory.

After each instructional circle model, each member wrote a reflection on their takeaway from that meeting. We were curious to see the benefits from the MTEs not presenting their specific problem of practice as well as how instructional circles afforded the development of a community of practice among university-based MTEs. We then analyzed our reflections to look for common themes among our experiences, and did member checks to verify our findings.

Initial analysis of our reflections surfaced two levels of support experienced by the MTEs. The first is concrete support for answering the problem of practice that was proposed. For example, Author 1 received advice from the group about using manipulatives in a fractions lesson, and a member of the group shared a useful article to assign to students related to the class activities. Application of the group's advice and resources resulted in a more interactive and cohesive lesson in Author 1's methods class. Secondly, MTEs found a supportive space for

Keywords: Teacher Knowledge; Equity, Inclusion, and Diversity

Understanding equity is an essential component in the improvement of mathematics and science teacher education (Gutiérrez, 2012; Jacobs, 2012). Although teachers have reported strong links between equity theory and practice in their credential programs (Athanases & Martin, 2006), the context and aims of equity-oriented education vary (Levinson et al., 2022). Additionally, there is little established research concerning equity and teacher leadership (Milner et al., 2015). We adopt Philip's (2011) *ideology in pieces*, which proposes that individual conceptualizations of equity are informed by lived experiences as well as shared social understandings, to understand teacher leaders' (TLs) shifting understandings of equity.

We studied a cohort of seven mathematics and two science TLs, working in urban schools, participating in a five-year teacher leader professional development. Participants included six who identify as women and three who identify as men from a mix of cultural backgrounds: four White/non-Latine, three Latine, one Vietnamese American, and one reporting mixed ethnicities. The TLs participated in four primary experiences, including meetings exploring equitable teaching practices for urban schools (Johnson et al., 2019).

Data included an open-response survey administered in the first year of the fellowship and an interview at the end of the fourth year. The survey asked the TLs to select amongst common historical definitions of equity (Pelaez, 2022), while interview allowed the TLs to elaborate on, and describe any changes to, their definition. The interview also asked the TLs to provide examples of how their understanding of equity is expressed in their teaching and to explain how the fellowship experiences influenced their thinking and practices related to equity. Preliminary analysis categorized responses into whether the TLs kept, changed, or modified their definitions. Additionally, we open coded the TLs' interview responses, looking for distinct ideas about how they enacted their definition in the classroom and what aspects of the fellowship they attributed their definition to. Open codes were thematically organized across participants, identifying themes related to changes in their definitions, enactment in the classroom, and their attribution to aspects of the fellowship (Creswell & Poth, 2018).

Eight of the nine TLs suggested changes to their chosen definition with many modifications focused on identifying student needs. When asked about how their definition manifests in their classroom, seven of the nine discussed taking time to get to know their students, arguing for definitions that ensure "every kid gets what they need." When reporting on components of the fellowship, they often attributed their definition of equity and teaching practices, to learning about equitable teaching practices in urban schools (Johnson et al., 2019). One limitation, particularly through the lens of ideology in pieces, is an omission of how each TLs' social positioning via their intersecting identities might impact their shifting definitions of equity.

DEPRIVATIZING INSTRUCTIONAL PRACTICE USING INSTRUCTIONAL CIRCLES

Matthew Melville
Purdue University Fort Wayne
mdmelvil@pfw.edu

Betsy Berry
Purdue University Fort Wayne
berrys@pfw.edu

Keywords: Professional Development, Mathematical Knowledge for Teaching, Teacher Knowledge

Background

The effectiveness of professional learning opportunities depends on their content and how the content is facilitated, *what* teachers' study, and *how* they study it (van Es et al., 2014; Kazemi et al., 2008; Kennedy, 2016). In my study, I focus on the way in which professional learning opportunities are facilitated, on how teachers are engaged in studying teaching.

Instructional circles are somewhat informal gatherings of small groups of teachers to discuss instructional practices (Melville, 2022). These circles seem oriented to analyzing specific practices and sharing advice rather than collectively designing a lesson or learning about a specific instructional method. Some local teachers and educators voluntarily attend instructional circle sessions that usually meet once every few months. Japanese teachers have described them as important professional learning activities that serve an essential function quite different from lesson study. This session will look at how instructional circles support the development of teachers' ability to critically discuss improvements to instructional practices enabled through the deprivatization of their practice.

U.S. teachers often have a difficult time deprivatizing their practice among other professionals (de Jong et al., 2019). Often when teachers do deprivatize their practice, three main types of interactions occur: giving praise, giving advice, and (uncommonly) engaging as challenging colleagues (Males, 2009). Engaging as challenging colleagues is less about critiquing the professionalism of the teacher but working together to improve the instructional practices found within a lesson. Thus, taking the focus from the teacher and put onto *teaching* (Hiebert & Grouws, 2007). This session will present how instructional circles are able to help teachers deprivatize their practice and engage as challenging colleagues to improve their instructional approaches to teaching.

Methods and Results

An ethnographic approach was taken to learn about how instructional circles engage U.S. teachers in deprivatizing their practice in a community of learners. We focused specifically on what teachers brought to the instructional circle, what they taught, and then how they felt the process beneficial for their learning. We did participant observations, interviews, artifact collection, and journaling.

So far, we have found that instructional circles addressed the need for a safe place for teachers to share their practice with others. In other words, teachers felt comfortable deprivatizing their practice to allow for high-quality discussions about the improvement of instructional practices as identified by the teachers themselves. Teachers were able to develop a community of learners through their focus on improving a specific aspect of the lesson plan. For example, one teacher was trying to increase student engagement and asked the other teachers for

their input. Teachers offered advice, but the focus was more detailed through the lens of trying to accomplish the learning goals.

LEARNING TO LEAD IN ELEMENTARY MATHEMATICS: DEVELOPING TEACHER LEADER CAPACITY TO SUPPORT TEACHER LEARNING

Alison Castro Superfine

amcastro@uic.edu

Deena Soffer Goldstein
University of Illinois at Chicago
dsoffe2@uic.edu

Keywords: Professional Development

Teacher learning is instrumental to math instructional improvement, and research sheds light on the kinds of teacher learning experiences that generate such practice change. We have known for decades that more ambitious instructional improvements, like those needed in math, require a sustained emphasis on teacher learning (Spillane & Thompson, 1997). While research has established that schools are critical contexts for teacher learning, many lack the infrastructure or culture to provide robust professional learning. As a result, fostering and systematizing the kinds of within-school learning experiences that are vital to teacher development has proven to be challenging. "Job-alike teams" (Gallimore et al., 2009), such as formalized grade-level or subject-oriented teacher teams, provide a natural structure for teacher learning (Weddle, 2022). Because they provide the kinds of ongoing time and space of value for sustained teacher learning throughout the year (Kyndt et al., 2016), teacher team meetings hold strong potential for providing learning experiences that are vital to teacher learning. Although research highlights the key roles that teacher leaders and principals play in supporting teacher learning, few interventions have been designed and tested to build the collaborative capacity of these leaders to develop teacher teams as effective teacher learning environments.

In this poster, we illustrate the design and implementation of a professional learning intervention, Learning to Lead in Math (LTL-Math) Project, focused on developing both math teacher leaders (MTL) and principals as co-leaders in and contributors to the support of teacher learning and instructional improvement in schools. The design of LTL-Math includes three components: (1) math teacher leader professional learning, (2) principal professional learning, and (3) school-based group coaching. In this poster, we focus exclusively on the first component, the design of the MTL professional learning. Drawing on prior teacher learning research (Horn, 2010), MTL learning focuses on the facilitation of a set of active teacher learning routines during teacher team meetings (i.e., lesson planning, analyzing instructional practice, examining student learning artifacts). Related to these routines, MTL learning experiences focus on promoting an understanding of how to support teachers in using instructional practice and artifacts as objects for collective instructional inquiry (Lesseig et al., 2017). This occurs as teacher practice becomes public within a teacher team (Kruse et al., 1996), all teachers on the team adopt an inquiry stance (Lieberman & Miller, 2001), and the team uses instructional practice as a learning resource.

During professional learning sessions, MTLs engage in active learning experiences using a modified version of the Learning to Lead cycle (Borko et al., 2021) and effective facilitation practices (van Es et al., 2014). These experiences include five phases in which MTLs *experience*, *analyze*, *practice*, *enact*, and *reflect* on teacher team meetings. MTLs begin by *experiencing* a simulated teacher team meeting modeled by a project coach, then *analyze* the facilitation of meeting activities, then plan and *practice* the facilitation of a teacher team meeting with targeted feedback on their rehearsals (Kazemi et al., 2016), then *enact* facilitation of a teacher team meeting in their school context, and finally *reflect* on the enactment. Throughout, MTLs learn to design, adapt, and use tools and practice artifacts to support teacher learning.

Keywords: Culture and Asset-Based Pedagogies; Equity, Inclusion, and Diversity

Asset based practices in mathematics instruction emphasize the importance of teachers identifying and using students lived experiences and experiential knowledge as foundational resources for teaching and learning. One of such frameworks is Funds of Knowledge (FoK) which that leverages students' family, community and cultural experiences for teaching (Moll et al., 1992). Research has reported higher student engagement, motivation and potential improvement in achievement when teachers connect the school mathematics to students' cultural, community, and family knowledge (Civil, 2007; Turner & Drake, 2016). This study investigates mathematics teachers views on FoK, specifically how they conceptualize it, elicit and integrate students FoK in mathematics instruction.

Methods

This study forms part of ongoing broader research involving K-12 mathematics teachers participating in a master teaching fellowship the United States. We interviewed seven mathematic teachers and observed three lessons from them. The interviews examined teachers understanding of FoK and the observations examined how Fok was integrated in classroom instruction. Data from the interviews and observations were coded and analyzed thematically.

Discussion and Implications

Three interrelated themes emerged around mathematics teachers' understanding, enactment and challenges with FoK.

Understanding FoK

Mathematics teachers conceptualized FoK as (1) students' prior academic knowledge (Denton & Borrego, 2021), (2) community-based cultural knowledge and (3) a process of formalizing everyday mathematics into school mathematics. These are family (farming, ranching etc.) and cultural (music, clothing, beadwork) based knowledge which were elicited through relationship building and involvement in school and community activities.

Enacting FoK

The analysis revealed an emerging instructional cycle: eliciting and recognizing → connecting and integrating → reflecting and refining. Teachers identified and connected students FoK to lesson plans before instruction, translated these FoK into mathematical representations, examples and tasks during instruction and the reflected on these connections and identified newly surfaced FoK to inform subsequent instruction.

Integration challenges

Teachers identified institutional constraints such as curriculum demands and limitation of instructional time as barriers to planning for FoK integration. Teachers' capacity (Hunter et al., 2024), family perception and parent expectation of what should be taught further complicated efforts to adopt FoK in instruction. These results imply that integrating FoK goes beyond the use of real-life examples in mathematics lessons, but it is an ongoing process of connecting students' experiences which is shaped by teachers choices and institutional constraints.

Given students' growing use of large language models (LLMs) for academic work, research is needed to examine how the cognitive demands of statistics tasks are mediated by LLMs. We examine the cognitive demands at which ten undergraduate students, in think-aloud interviews, solved two expected value problems with access to ChatGPT. We found that choosing not to use ChatGPT did not guarantee that students resolved tasks at higher levels of cognitive demands than those who did use it. We also found evidence that LLMs can support students in connecting task language to relevant constructs and making progress when they lack an initial strategy. The interviews also highlight the role students play in verifying LLM-outputs and in self-monitoring their problem-solving processes, both of which are critical for high-demand problem-solving.

Keywords: Statistics, Large Language Models, Cognitive Demand

A long-standing discussion in mathematics education research concerns the cognitive demands of mathematics tasks (Doyle & Carter, 1984). This discussion has distinguished the demands as intended by task designers from the demands that emerge as instructors enact tasks with their students (Stein et al., 1996; Stein & Smith, 1998). Existing research has noted the impacts that students' uses of technology have on cognitive demands of tasks as they solve them (Sherman, 2014). Recognizing that statistical activities, while distinct from mathematical activities, blend mathematical and non-mathematical knowledge and thinking (Groth, 2007), we extend this discussion to the cognitive demands of students' problem-solving on statistics tasks.

The growing prevalence of AI tools, particularly large language models (LLMs), among undergraduate students (Morell-Mengual et al., 2025) and their increasing adoption by universities (Ford & Knox, 2025) have raised questions about their impact on students' problem-solving practices. LLMs occupy a unique position compared to other technologies. LLMs can serve functions like tools commonly used in mathematics and statistics classrooms, such as calculators. However, they also introduce features and limitations not captured by existing descriptions of other technologies. For instance, LLM-generated outputs can mimic student thinking and reasoning and, in some cases, correctly explain concepts or solve problems. These outputs, however, are generated stochastically and require user verification. These differences invite the question of how LLMs may impact the level of cognitive demands at which students solve tasks, which may differ from what their teacher or the curriculum designer intended.

This study investigates the cognitive demands that students take on as they solve problems with LLMs. We also build on discussions that consider how features of LLMs, such as their ability to generate explanations and illustrative examples of statistical concepts, may support students' statistical reasoning (Ellis & Slade, 2023). Here, we examine if these kinds of benefits (or limitations) emerge as students solve these problems. To that end, we ask: *How does an LLM mediate the level of cognitive demands at which undergraduate students solve probability tasks?*

Theoretical Framing

Cognitive demands refer to the "cognitive processes in which students actually engage in as they go about working on the task," (Stein et al., 1996, pg. 461). There has been a historical

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

focus on sustaining high-demand tasks because the types of thinking and reasoning that students do ultimately influence what mathematics they will learn (Doyle & Carter, 1984). Stein and Smith (1998) characterized cognitive demands in their Mathematics Tasks Rubric (1998), an artifact of the QUASAR project, organized in a four-level hierarchy that describes low-to-high thinking demands that students may employ, depending on how the task is written and how they interpret what they are asked to do. A task may require students to rely on *memorization (low demands)*, involving the reproduction of previously learned facts, rules, formulas, or definitions with no connection to underlying concepts. Tasks may emphasize *procedures without connections (low demands)*, in which students apply algorithmic procedures in routine ways that focus on obtaining correct answers. *Procedures with connections (high demands)* requires students to use procedures to make sense of mathematical ideas in context, often requiring attention to underlying concepts and representations. Finally, tasks categorized as *doing mathematics (high demands)* require non-algorithmic thinking, including exploring relationships, navigating multiple solution pathways, and engaging in sustained reasoning and self-monitoring. These levels can be used to characterize the cognitive demands of tasks at various stages of enactment. This suggests (and prior work supports that) cognitive demands of tasks can be mediated temporally from their written, set up, and solved forms (Smith et al., 2007).

The level of cognitive demands at which a student solves a task may differ from that intended by designers of the task. One reason could be the tools that students use while solving. Sherman (2014) extended Stein et al.'s work to show that students' uses of technologies can further mediate the cognitive demands at which students solved tasks: technologies only help students sustain high cognitive demands when they reorganize (Pea, 1985) student thinking in ways that shift their focus to high-demand aspects. For instance, when students use graphing calculators, their thinking demands may shift to interpreting multiple graph-based models in context (*high demands*). Whether students can sustain high cognitive demand while working on tasks with LLMs remains an open question, since many of today's LLMs can solve many undergraduate mathematics tasks correctly most of the time. Recent work examining students' problem-solving with LLMs has suggested that cognitive demands largely depend on what students prompt them to do (e.g., Wu et al., 2025; Yoon et al., 2024). In Wu et al.'s study, students who checked their chatbot's work with resources from their statistics class retained more thinking demands than students who solved the task solely through LLM-mediated interactions. However, these studies have not measured cognitive demand directly or examined how students' thinking processes may alter the cognitive demands of tasks. We address this gap through the following analysis.

Methods

Interview Structure and Task

The work reported here is drawn from a larger study investigating how undergraduate students solve mathematics problems with access to GenAI tools (Delaney et al., 2025). Twenty participants were recruited via flyers posted in public spaces at a public university in the western United States. Students were eligible if they had taken at least one mathematics, probability, or math-intensive STEM course within the past 12 months; the final sample included both STEM and non-STEM majors. We conducted individual think-aloud cognitive interviews (Goldin, 2000) in which each participant solved three multi-part tasks spanning college algebra, probability, and calculus topics. One researcher served as the lead interviewer while the other managed the recording and took notes. The interview setup included a laptop open to ChatGPT-4o, which was selected because the institution provided students with ChatGPT subscriptions. However, students were allowed to use any generative AI tool they preferred, such as Claude or

Gemini, or not use any generative AI tools at all. Two researchers conducted each interview. The interviewer asked follow-up questions to clarify participants' ideas and to understand how GenAI, when used, supported their problem-solving.

This paper focuses on the second and fifth items of the probability task, named the *ATM Task*, adapted from a question in a previous AP Statistics examination (College Board, 2015; see Figure 1). The second item, which we label as the *expected value item*, was still intended to motivate the calculation of the expected value. However, we replaced "expected value" with "average" to raise the item's cognitive demand, requiring participants to either recognize that the expected value formula or infer what "average" means in the context of a discrete probability table. The fifth item, labeled the *conditional expected value item*, was given as written.

A shopping mall has three automated teller machines (ATMs). Because the machines receive heavy use, they sometimes stop working and need to be repaired. Let the random variable X represent the number of ATMs that are working when the mall opens on a randomly selected day. The table shows the probability distribution of X.

X = Number of ATMs working when the mall opens	0	1	2	3
Probability	0.143	0.286	0.429	0.143

Item 2. On average, how many ATMs will be working on any given day?
Item 5. Given that at least one ATM is working when the mall opens, would the average number of ATMs working on any given day be less than, the same, or greater than the average you found in question 2? Explain your answer.

Figure 1: Excerpt of the ATM Task

Data Analysis

Our findings come from an analysis of 10 participants who completed both the expected value and conditional expected value items. This group consisted of eight female students, one male student, and one non-binary student, representing both STEM and non-STEM majors. All participants had taken a mathematics course, or a course involving mathematics, during the academic year in which the data were collected. The first and third authors served as raters and reviewed video recordings, written work, and field notes from data collected from these ten participants. They assigned a cognitive demand rating to each participant's solution. Ratings were based on criteria from the Mathematical Tasks Framework (Stein & Smith, 1998), adapted to account for the forms of thinking and reasoning relevant to solving the expected value and conditional expected value items of the ATM Task (see Table 1).

Table 1: Stein & Smith (1998) Framework Applied to Expected Value Items

Level	Expected Value Item	Conditional Expected Value Item
0 - N/A *Guessing, non-mathematical reasoning.*	Guessing without procedures or mentioning previously learned facts, rules, or definitions about expected value.	Guessing without procedures or mentioning previously learned facts, rules, or definitions about conditional probability or expected value.
1 - Memorization *Involves either reproducing facts, rules, formulas, or definitions.*	Reproduces a fact or definition about averages or expected value. *Example:* A student describes the expected value as the long-run average of a random variable.	Reproduces memorized ideas about conditional probability (e.g., a formula) and/or expected value. *Example:* A student only recalled the conditional probability formula.

2 - Procedures without Connections *Focused on correct answers, does not connect to underlying meaning.*	Produces an answer using a procedure without making sense of the computed value or the underlying reasoning. *Example:* A student claims that $E(X) = 0(0.143) + 1(0.429) + 2(0.429) + 3(0.143) \approx 1.57$ working ATMs, on average.	Attempts to solve the problem via a procedure with little to no conceptual explanation of how conditioning changes the probability distribution. *Example:* A student computes conditional probabilities and obtains $E(X) = 1(0.334) + 2(0.500) + 3(0.167) \approx 1.83$ working ATMs if $X \geq 1$.
3 - Procedures with Connections *Procedures for the purpose of developing deeper levels of understanding of mathematical concepts.*	Produces an answer using the standard formula and reasons or makes sense of the computed value or the process behind obtaining the value. *Example:* A student completes the calculation above and checks the result by identifying the median of the distribution.	Solves the problem via a procedure but connects the procedure with an explanation showing how conditioning changes the distribution (e.g., describing the impact of removing $X = 0$ on the other probability values). *Example:* A student completes the calculation above and connects this value with the assumption $X \geq 1$.
4 - Doing Mathematics *Complex, nonalgorithmic thinking, make use of relevant knowledge and experiences*	Determines the average using conceptual reasoning rather than formulaic computation; justifies the result using the structure noticed in the item. *Example:* Without a formula, a student explains that the heavier probabilities of $X = 1$ and 2 pull the average to be between those values.	Uses structural reasoning (not a procedural method) to justify the comparison, for instance, by explaining how eliminating $X = 0$ produces a conditional probability distribution. *Example:* Without performing the standard calculations, a student reasons that, given $X \geq 1$, the probabilities for $X = 1$, 2, and 3 increase proportionally, leading to a greater average.

We recognized that students can engage with a single item at multiple levels of cognitive demand while solving (Boston, 2006). Thus, we assigned ratings solely according to the participants' *resolution* of the item (Boston & Candela, 2018). For instance, a student might initially reason about the conditional expected value item in ways that reflect *doing mathematics*, but then abandon that reasoning in favor of applying statistical formulas, resulting in a code of *procedures without connections*. We also assigned ratings based on the nature of participants' problem-solving (as detailed by Stein and Smith's (1998) descriptions, not correctness. The raters initially coded the solutions independently, reaching agreement on 70% of the ratings. They then clarified the assigned ratings and the criteria themselves until reaching full agreement. For example, these discussions clarified when a resolution should be coded as not applicable and what kinds of non-algorithmic work and explanation could constitute doing mathematics.

Findings

We begin with the intended cognitive demands of the two items as a baseline. We determined these demands by reviewing solutions published by the Advanced Placement program. The published solution to the expected value item employs the formula for the expected value of a discrete random variable. We rated this solution as *procedures without connections*, since the written solution did not require students to make sense of the expected value in relation to the

data distribution. The written solution to the conditional expected value item, on the other hand, required students to observe that $X \geq 1$ would result in a new distribution where the probability values would be rescaled proportionally to sum up to 1, thus increasing the expected value. We rated this solution as *doing mathematics* as it entailed a non-algorithmic approach that notices the relationship between a conditional event and expected value.

Figure 2 summarizes the cognitive demand ratings the authors assigned to each participant's solution to the expected value and conditional expected value items, along with the time spent solving each item and whether ChatGPT was used on either item. The findings are organized below by task item. As emphasized in the research question, we pay special attention to how participants' resolutions were mediated by their interactions with ChatGPT.

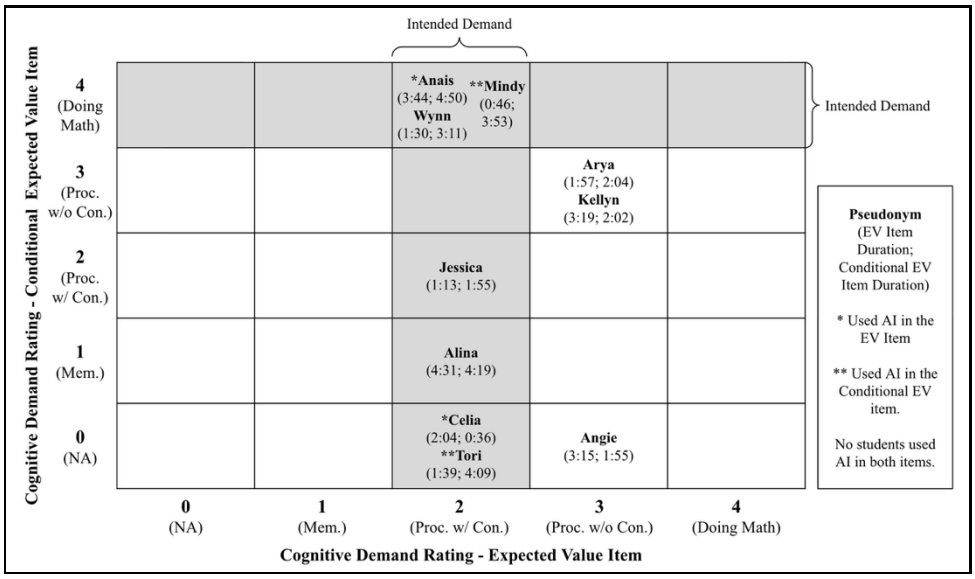

Figure 2: Summary of Cognitive Demand Ratings

Expected Value Item

This item asked for the average number of ATMs working on a given day. All ten participants had resolutions coded at the intended level of cognitive demands, *procedures without connections*, or higher. Because of this, we divide our findings related to this item based on whether the participants' resolution was rated as solved with high cognitive demands.

High cognitive demands. Three participants resolved the item at the level of *procedures with connections*, with none using ChatGPT. These participants computed the expected value using the standard algorithm and reasoned aloud about their final answer by triangulating it with another measure of center for the probability distribution. For example, Kellyn completed an identical procedure, obtaining 1.57, and argued that the value was reasonable since "looking at the probability values, I would expect [the average] would probably fall between 1 and 2." Here, she was using her notion of center in the probability distribution to triangulate her work.

Low cognitive demands. Seven participants resolved the expected value item using solutions we rated as *procedures without connections,* aligning with the task item's intended level. Five of these participants did not use ChatGPT and employed a range of strategies. Notably, only one participant, Wynn, applied the formula for the expected value of a discrete random variable, doing so correctly but without articulating any reasoning to justify the

procedure or the reasonableness of the resulting value. The remaining four participants relied on non-normative procedures to determine an average, such as selecting the X value associated with the greatest probability or computing the average of the probability values.

The other two participants in this group, Celia and Anais, used ChatGPT while solving the item. Celia, who was in the AI-Only condition, used ChatGPT solely as a calculator to implement her own approach of averaging the given probability values. Anais, in contrast, prompted ChatGPT in ways that supported her solution to the problem beyond computation.

Upon reading the task item, Anais expressed uncertainty about how to proceed, stating, "It's something that's catching me. [The problem] doesn't look familiar. I don't have a sense of direction on where to go." Anais then prompted ChatGPT with a general query about how to find an average given X values and their probabilities (Figure 3). ChatGPT generated an output that connected the notion of "average" with expected value and provided a worked example.

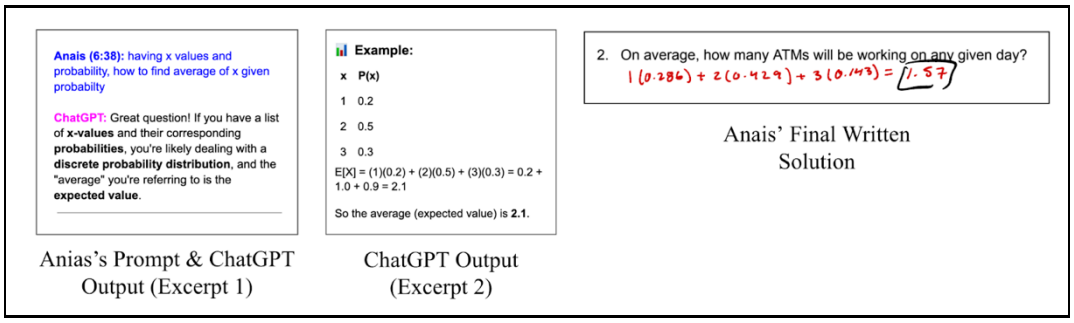

Figure 3: Excerpts of Anais' Interactions with ChatGPT and Solution

Anais reflected on how ChatGPT's example aligned with the task components: "[ChatGPT] gave me an example of essentially the information I have, which is X values and probability, and finding the expected value, which is what the question is asking." She adopted ChatGPT's connection between "average" and "expected value" and correctly applied the procedure to obtain 1.57. Discussing her solution, she emphasized the familiarity of the formula rather than interpreting the result in relation to the context or the given probability distribution, stating, "I [have seen this formula] in high school … These symbols right here, everything looks familiar."

Conditional Expected Value Item

This item asked if and how the average number of working ATMs would change under the condition $X \geq 1$. We organize findings related to this item based on whether participants resolved the task item at or below the intended level of cognitive demand, *doing mathematics*.

At intended cognitive demand. Three of the participants (Anais, Mindy, and Wynn) solved the item at the level of *doing mathematics*. In general, these participants hypothesized, without assistance from ChatGPT, about how conditioning would affect both the probability distribution and average, with varying levels of accuracy in their implementations and explanations. Wynn, for example, produced diagrams illustrating how the probability values would change proportionally under the condition to reason that the average would increase.

Mindy was the only participant in this group who used ChatGPT while solving the item. Her use of ChatGPT was limited to using it as a calculator for an initial attempt at the problem. However, she abandoned this attempt and instead solved this item using similar reasoning as the other two participants, which led to her resolution being rated as *doing mathematics*.

Below intended cognitive demand. The remaining seven participants resolved the conditional value item below the intended written level of cognitive demands. Two of these participants, Arya and Kellyn, had resolutions rated as *procedures with connections*, thus still representing high-demand solutions. These solutions contained similar ideas to those described above, but rooted in the completion of a procedure as opposed to non-algorithmic reasoning about the condition. Arya, for example, argued that the same calculation applied to the expected value and conditional expected value items. He reasoned that outcomes with a value of 0 "don't contribute to the average" because "anything you multiply by zero is just going to be zero," and therefore only including the values of X where $X \geq 1$ and their probabilities would not change the result. On this basis, he concluded that the average, under the condition, would not change.

The resolutions from the remaining five participants (Tori, Celia, Angie, Alina, and Jessica) were rated at lower levels of cognitive demand. While the thinking from these participants varied widely, these participants generally struggled to interpret and account for the condition $X \geq 1$. For example, two treated the item as a comparison of previously computed values rather than reasoning about how the condition affected the probability distribution and the expected value. Tori was the only participant in this group to prompt ChatGPT in response to the condition.

Tori immediately expressed uncertainty about how to solve the problem, indicating difficulty interpreting the word "given" in the item statement after struggling with a prior conditional probability item. She then prompted ChatGPT (Figure 4) with the text of the conditional expected value item, but copied the prompt incorrectly (e.g., writing "greater than the average of 2 ATMs" instead of "greater than the average you found in Question 2"). ChatGPT's response, organized into two steps (headings not pictured). ChatGPT first calculated an expected value without considering the condition (an unnecessary step given the prompt). It then computed the conditional expected value by determining conditional probabilities and recomputing the expected value and concluded that the conditional expected value was less than two.

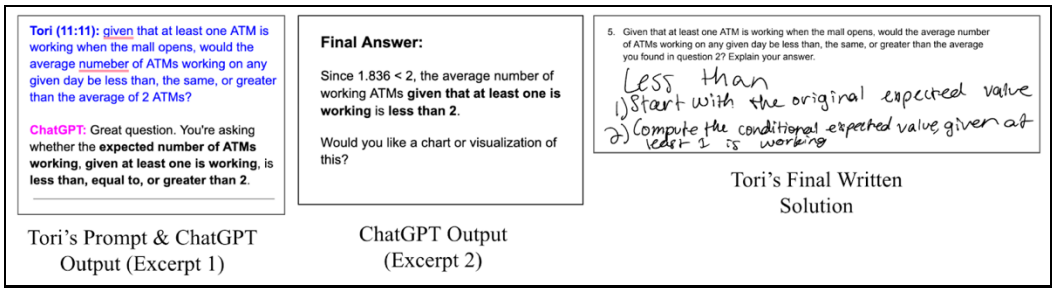

Figure 4: Excerpts of Tori's Interactions with ChatGPT and Solution

In resolving the task item, Tori accepted ChatGPT's answer of "less than" and copied the headings on her written work. In doing so, she wanted "to explain [her] answer" and that she might "just use the steps that it gave [her]." Tori clarified, however, that without understanding what "given" implies for solving the item, she had no way of verifying whether or not ChatGPT's output was correct. Thus, she herself noted the potential fallibility of ChatGPT's output, while also acknowledging that her limited knowledge left her unable to verify the solution. However, we note that she did not use ChatGPT to attempt resolve this missing understanding. Tori's resolution of the task item was rated as *not applicable,* as she accepted ChatGPT's output with little evidence of sense-making about its contents.

Discussion

Our findings extend the field's understanding of how cognitive demands are mediated in statistics and how some students' LLM uses contribute to changing probability tasks' demands. Notably, six of the ten participants did not use ChatGPT on either task item. However, abstaining from LLM-use did not seem to influence the demands at which they solved the tasks with respect to the designers' intentions. This introduces questions of what LLMs could have afforded to students who were less accurate or worked at lower levels of demand on either item. For instance, Celia, Angie, and Alina resolved the conditional expected value item at the levels of *memorization* and *NA*. They did not prompt ChatGPT, despite struggling with accounting for the condition. Had they used ChatGPT as a reference to account for the condition, could they have been better positioned to engage with the item at a higher level of cognitive demands?

Anais and Tori used LLMs to mediate the task's demands, and were similar in that they prompted ChatGPT to progress when they did not know how to proceed. For Anais, ChatGPT served as a reference to obtain a general procedure for the expected value item that she could apply and eventually resolve the task at the level of *procedures without connections*. For Tori, ChatGPT provided a full solution to an incorrect version of the conditional expected value item that she was unable to make much sense of, leaving her resolution rated as *NA*. We also saw that for Celia and Mindy, LLM-use did not appear to alter the cognitive demands of their solutions, as they had their own approaches and solely used ChatGPT as a calculator.

Our descriptions of students' problem-solving also suggest that students engaged in self-monitoring (Flavell, 1979) while reviewing outputs from ChatGPT, albeit to a limited extent. Specifically, Anais and Tori expressed gaps in their knowledge, turned to ChatGPT accordingly, and appeared to reflect on what they did and did not understand (Fan et al., 2025) about the statistical content of the task. However, we also observed that none of the participants who used ChatGPT checked the results or generated follow-up prompts to triangulate the information they obtained from their initial queries. For instance, Tori acknowledged her limited subject-matter knowledge for the conditional expected value item but did not pursue follow-up prompts that might have deepened her understanding of the relevant probability concepts. This pattern raises concerns regarding cognitive demands in LLM- mediated problem-solving, as high-demand problem-solving requires students to "access relevant knowledge" (p. 348) necessary for solving and understanding problems and monitor their knowledge and thinking (Stein & Smith, 1998). These findings suggest that students may need explicit motivation to monitor their understanding of and follow-up with LLM-generated outputs to better emulate high-demand problem solving.

Of course, our findings and discussion should be interpreted in light of the study's limitations. The low-stakes interview setting may restrict the applicability of the findings to other contexts, such as problem-solving in the context of coursework where participants obtain a grade. The think-aloud structure of our interviews may have prompted students to think more metacognitively than in settings outside of the interview-context. Additionally, the conditional expected value item was placed at the end of the *ATM Task*, and some students may have felt hurried to complete it, which may have impacted their approach to solving the problem.

Nevertheless, our analysis suggests that LLM-use does not inherently shift the cognitive demands of students' problem-solving. Rather, cognitive demands may be more contingent on the ways students employ LLMs as well as their own metacognitive thinking and actions. Future work should examine how students can learn to recognize gaps in their knowledge, strategically employ LLMs to address these gaps and obtain information needed to progress in a problem, and engage in verification and reflection about LLM outputs when such tools are permitted.

This study examined how Nigerian secondary school students understand key probability vocabularies—fair, independent, likely, and random—within a multilingual and culturally embedded context. Guided by an explanatory sequential mixed-methods design, data were collected from 120 students using a Probability Vocabulary Meaning Test and from 24 students through semi-structured interviews. Quantitative findings showed a moderate overall understanding of probability terms, with marked difficulties in technical concepts such as mutually exclusive (30%) and independent (33%). Qualitative results revealed pervasive semantic interference, as students frequently relied on every day and culturally shaped interpretations of fairness, chance, and fate. Analysis informed by Vosniadou's Framework Theory of Conceptual Change indicated that most students assimilated probabilistic vocabulary into naïve cognitive frameworks, with few achieving full conceptual accommodation.

Keywords: Probability

Today, the world is driven by data, and the ability to think probabilistically is an important aspect of critical reasoning and mathematical literacy (Garfield & Ben-Zvi, 2008; Gal, 2005). Comprehending probability provides people with the opportunity to make informed decisions in various daily life contexts, ranging from assessing risk in health and financial domains to interpreting weather forecasts. Accordingly, many nations have incorporated probability concepts into the primary school curriculum to develop foundational skills for innovative statistical thinking (Batanero et al., 2016). Notwithstanding its rising significance, probability appears to be one of the most difficult aspects of school mathematics. Unlike algebra or arithmetic, where methods and solutions are exact and often obvious, probability deals with prediction, chance, and uncertainty. The intellectual swing from deterministic reasoning—imagining patterns and certainty—to probabilistic reasoning, which embodies degrees of beliefs and randomness, is significant (Pratt, 2000; Kahneman & Tversky, 1972). This theoretical intricacy is echoed in dogged challenges students come across when learning the concept of probability (Shaughnessy, 1992). An important source of challenge lies in the linguistic context embodying probability concepts. Textbooks and classroom discourse in probability present many specialized technical terminologies—such as mutually exclusive, independent, fair, likely, and random—that have twin or several connotations. In plain linguistic context, these terminologies convey informal or traditionally rooted elucidations that often deviate from prescribed scientific definitions (Watson & Moritz, 2003; Batanero et al., 2014). For example, while random in statistics depicts results created by a distinct probabilistic procedure, in everyday plain conversation, it might mean disorganized, erratic, or influenced by chance or fate events.

Equally, fair can imply moral equality or social justice rather than the equiprobable nature of outcomes in probability education.

This language vagueness is a source of semantic interference, where students hold on to their everyday connotations even after formal education, obstructing complete conceptual understanding (Gal, 2005). Students may have excellent response to probability problems procedurally, yet their elucidations or casual reasoning show mixed contexts uniting subjective beliefs, moralistic, and deterministic views (Batanero et al., 2016). Such twin connotations and everyday extrapolations produce blockades to deep understanding of probability concepts. This challenge of probability vocabulary is further compounded in polyglot didactic settings. In some countries, together with Nigeria, students are often taught mathematics in a language different from their mother tongue, thereby heightening the intricacy of language mediation (Watson & Moritz, 2003). Nigeria is culturally and linguistically diverse, with English as the lingua franca alongside numerous dominant mother-tongues such as Hausa, Igbo, and Yoruba, which are default languages in students' communities and homes (Federal Ministry of Education, Nigeria, 2013). The multilingual nature of mathematics classrooms in Nigeria may present translation challenges or variable elucidations formed by homegrown cultural tales and beliefs about fairness, luck, and chance (Fischbein & Schnarch, 1997). These cultural beliefs may intensely impact probabilistic reasoning among Nigerian students. In many societies in Nigeria, events may be professed as ruled by divine will, destiny, or fate—a deterministic worldview that contradicts the probabilistic reasoning needed in mathematics. In addition, moral elucidations of justice and fairness often interweave with the statistical construct of "fairness" in probability, obscuring students' capability to extricate informal connotations from prescribed characterizations (Gal, 2005).

Research on probability misconceptions has largely focused on routine mistakes, intellectual preconceptions, or conceptual misinterpretations gleaned from cultural and linguistic dimensions (Fischbein, 1975; Konold & Pollatsek, 2002). Although a rising body of literature recognizes the importance of language in teaching and learning of probability concepts (Batanero et al., 2014; Watson & Moritz, 2003), very few studies have meticulously investigated how probability terms or vocabularies are construed in polyglot, customarily varied African settings. This dearth of empirical evidence is particularly more pronounced in Nigeria, where the intersection of cognition, culture, and language needs cautious pragmatic examination to inform effective teaching and learning. Comprehending students' elucidations of probability terminology in this setting is important for fashioning educational pedagogies that promote real conceptual change rather than superficially shallow learning. In the absence of clear attention to the cultural narratives and language nuances students bring to the teaching space, mathematics instruction risks strengthening misconstructions concealed in superficial accuracy (Jones et al., 2007). Teachers often assume common denotations of probability vocabularies, which may be acceptable in similar language sceneries but not in polyglot teaching space where word connotations are exchanged and disputed (Gal, 2005). This study is theoretically grounded in the Framework Theory of Conceptual Change (Vosniadou, 1994; 2007), which postulates that students unify knowledge into lucid but often inexperienced cognitive models that contradict simple replacement by official constructs. Conceptual change encompasses the addition of new facts and the reorganization of existing frameworks through accommodation, synthesis, and assimilation. Applying this theory to probability vocabulary, predicts that students' linguistic preference shows their causal conceptual frameworks—whether they genuinely restructure their understanding to accommodate mathematical concepts, create hybrid models blending old and

new ideas, or retain everyday meanings (Vosniadou et al., 2001). Supplementing this mental viewpoint is the theory of sociocultural learning (Vygotsky, 1986), which postulates language as a tool of mediation. Teaching and learning of probability terminology in a polyglot context includes circumnavigating not only mental mathematical characterizations but also translation procedures and social connotation-making. Traditional beliefs about causality, fairness, and chance shape how students understand constructs and engage with instruction in formal setting (Batanero et al., 2016). Incorporating these frameworks shows how linguistic and conceptual factors are intertwined in the teaching and learning process of mathematics. Therefore, this study investigated how Nigerian secondary school students construe key probability vocabularies through mixed-methods explanatory sequential research design.

Research Questions

The following research questions were answered in this study:

1. What meanings do students attribute to probability vocabularies like fair, independent, likely, and random, and how do these vary by gender and grade?
2. How do students' explanations reflect conceptual frameworks of chance and uncertainty according to the Framework Theory of Conceptual Change?
3. What cultural and linguistic factors influence students' ability to differentiate mathematical and everyday connotations of probability terminologies?

Methodology

Participants

The study population comprised 22,832 senior secondary school (SS1–SS3) students enrolled in 28 public senior secondary schools within the Ikorodu Local Government Area of Lagos State, Nigeria. This locale was selected due to its representative linguistic and cultural diversity, encompassing urban, suburban, and rural communities, thus providing a varied sociolinguistic context for studying probability vocabulary learning. A purposive stratified sampling strategy was used to recruit participants to ensure representation by school type (urban public, rural public), grade level (SS1, SS2, SS3), gender (male, female), and language background (Yoruba, Igbo, and Hausa) from one senior secondary school. The total sample consisted of 120 students (40 per grade level), for the quantitative phase balanced for gender and linguistic diversity, including students who spoke English as a second language alongside Yoruba, Igbo, or other indigenous languages at home. For the qualitative phase, a subsample of 24 students was selected using maximum variation sampling based on PVMT performance (high, medium, low scorers), gender, and language background to provide a rich cross-section of students for semi-structured interviews. This nested sampling enhanced methodological rigor by aligning qualitative inquiry closely with quantitative patterns (Creswell & Plano Clark, 2018).

Research Design

This study adopted an explanatory sequential mixed methods design to investigate how Nigerian secondary school students interpret and use probability vocabulary terms such as random, likely, independent, and fair. The rationale for employing a mixed-methods approach stems from the need to obtain both breadth and depth of understanding about students' conceptual frameworks as well as the linguistic and cultural factors shaping their interpretations. Mixed methods research combines quantitative and qualitative techniques to allow for triangulation and complementarity (Creswell & Plano Clark, 2018; Dawadi & Giri, 2021). This approach enhances interpretive validity by cross-verifying findings from different data sources

and methods. The exploratory design is particularly suited to uncovering nuanced interpretations embedded in students' everyday language and cultural contexts, which purely quantitative measures alone cannot reveal (Batanero et al., 2016). Similarly, the qualitative strand gains strength and generalizability by being embedded within a larger quantitative assessment framework. This design aligns well with the study's guiding framework, the Framework Theory of Conceptual Change, which implies that student ideas are complex and organized within coherent but naïve frameworks requiring deep investigation (Vosniadou, 1994).

Instruments

Two instruments were used for data collection in this study. They were Probability Vocabulary Meaning Test (PVMT) and Semi-Structured Interview Protocol. The PVMT is a researcher-developed diagnostic tool designed to quantitatively assess students' understanding of key probability vocabulary terms within contextually relevant scenarios. The instrument consists of 15 items combining multiple-choice and open-ended questions, constructed to elicit definitions, explanations, and applied reasoning for terms such as random, likely, fair, independent, and mutually exclusive. The PVMT was developed based on a literature review, curriculum analysis, and consultation with mathematics education experts. Care was taken to embed vocabulary items within realistic probabilistic contexts familiar to Nigerian students (e.g., coin toss, dice rolls, spinners). The instrument was piloted with 30 students from a non-participating school to evaluate clarity, cultural appropriateness, and psychometric properties. Item analysis led to refinements that improved internal consistency, with the final version attaining a Kuder-Richardson 20 reliability coefficient of 0.86, indicating good reliability for research purposes. The multiple-choice items provided objective measures of vocabulary comprehension, scored dichotomously (1 = correct, 0 = incorrect). Open-ended questions complemented these by allowing expression of reasoning and identification of the semantic models used.

Semi-structured Interview Protocol

To deepen insight into the quantitative findings, semi-structured interviews were conducted with 24 students selected for diverse performance profiles and backgrounds. The interview protocol was developed after preliminary analysis of PVMT responses and was aligned conceptually with the Framework Theory of Conceptual Change. Open-ended questions probed students' interpretations of probability terms in their own words, experiences with probability concepts in and outside the classroom, perceived differences between every day and mathematical meanings, and cultural beliefs influencing their understanding. Interview questions were piloted and revised to ensure clarity and cultural sensitivity. Interviews were conducted individually during school hours in English, with students permitted to use local languages for explanations where necessary. This bilingual flexibility helped capture authentic linguistic reasoning. Interviews averaged 30-45 minutes, were audio-recorded, transcribed verbatim, and translations incorporated during transcription where needed.

Data Collection Procedure

Data collection was strategically staged to align with mixed-methods integration principles (Fetters et al., 2013). Ethical approval was obtained from the relevant Institutional Review Board and the State Ministry of Education. Permission was secured from school authorities, and parental consent and student assent were obtained prior to data collection. The PVMT was administered in classrooms under standardized conditions during scheduled mathematics lessons. Instructions emphasized honest and thoughtful responses, particularly for open-ended items. Students were given 60 minutes to complete the test to allow adequate time for reflection.

Immediately after PVMT administration, item scoring and descriptive statistics informed the selection of interview participants to represent performance and demographic diversity. Interviews were conducted within two weeks following PVMT upon participant availability. Researchers established rapport, ensured confidentiality, and clarified that there were no "right" or "wrong" answers to encourage candid discussion. All data were anonymized using pseudonyms. Digital files were password-protected, and transcripts were stored securely. Only authorized researchers had access to identifiable data.

Data Analysis

PVMT data were entered and analyzed using SPSS (version 27). Initial descriptive statistics (frequencies, percentages, means, and standard deviations) assessed overall vocabulary comprehension levels. Inferential statistics of one-way ANOVA and independent samples t-test tested for differences in vocabulary understanding across grades and genders respectively. Interview transcripts were analyzed thematically. The coding framework was developed deductively from the Framework Theory of Conceptual Change constructs (assimilation, synthesis, accommodation) (Vosniadou, 1994) and inductively from emergent linguistic and cultural themes. Two researchers independently coded a subset of transcripts to establish intercoder reliability, obtaining Cohen's kappa of 0.87, considered high agreement. Discrepancies were discussed and resolved through consensus. Coding continued iteratively with emerging themes refined accordingly. Major themes included semantic interference patterns, cultural beliefs influencing vocabulary interpretations, negotiation of everyday versus school meanings, and evidence of conceptual reshaping.

Results

Research Question 1

What meanings do students attribute to probability vocabularies like random, likely, independent, and fair, and how do these vary by grade and gender?

Table 1: Percentage of Students Selecting Correct Definitions by Term and Grade Level

Probability Term	% Correct (SS1)	% Correct (SS2)	% Correct (SS3)	Overall % Correct
Random	30	42	55	42
Fair	46	61	70	59
Likely	40	55	65	53
Unlikely	38	49	58	48
Certain	62	74	81	72
Independent events	20	33	45	33
Mutually exclusive events	18	31	42	30

Table 1 displays the percentage of students choosing the correct mathematical meanings for each target vocabulary term across grades SS1, SS2, SS3, and overall. Statistical analyses (one-way ANOVA) confirmed significant grade-level progression for all terms ($p < 0.01$), indicating that older students demonstrated better mastery of technical vocabulary. However, even at SS3, less than half correctly identified independent and mutually exclusive terms. Gender differences were not statistically significant ($p > 0.05$).

In the qualitative phase, interview responses revealed that students frequently used every day and culturally informed meanings for vocabulary, particularly at lower grade levels. On random, Ada (SS1) said, "Random means something that just happens anyhow without reason, like when someone suddenly shouts in class," reflecting everyday notions of spontaneity and chaos rather than mathematical randomness. For fair, Chika (SS2) explained, "A fair game is when everybody agrees on the rules, and nobody cheats." This social justice interpretation was common, overshadowing the equiprobable meaning. Regarding this, Mary (SS2) stated, "It is likely that my team will win because they are the best." This subjective, belief-based interpretation contrasts with probabilistic likelihood. On independent, Musa (SS2) noted, "Two events are independent when they don't know each other, like two friends living far apart," revealing a misinterpretation equating independence with causal or social unrelatedness rather than probabilistic independence. This qualitative data illustrates the semantic interference and everyday conceptual frameworks that underlie students' vocabulary use.

Research Question 2

How do students' explanations reveal conceptual frameworks of chance and uncertainty according to the Framework Theory of Conceptual Change?

Table 2: Quantitative Summary Coding

Conceptual Category	% of Interviewees
Assimilation	58
Synthetic models	30
Accommodation	12

Using Vosniadou's conceptual categories, students' responses were coded (Table 2) into assimilation (retaining everyday meanings), synthetic models (hybrid interpretations), and accommodation (scientifically accurate understanding). Most students exhibited assimilation, using probability vocabulary with everyday meanings without restructuring underlying concepts. Synthetic models involved partial accommodation but unstable blends of formal and informal ideas. Only a minority achieved full accommodation. This is supported by qualitative analysis. For Assimilation: Sola (SS1) said, "Random is when something happens without planning, like my brother surprising me." The term retained everyday unpredictability without probabilistic depth. For Synthetic Model: Tunde (SS3) on random stated, "Random means every outcome has the same chance, but sometimes it feels like luck controls it too." This hybrid view blends formal equiprobability with intuition about fate. For Accommodation: Funmi (SS3) explained, "Random means all outcomes are equally likely; for example, a fair die roll where each face has a 1/6 chance independently." This reflects a restructured probabilistic framework. These patterns confirm the difficulty in achieving true conceptual change, as predicted by framework theory, and underscore the linguistic and cognitive complexity of probability learning.

Research Question 3

What linguistic and cultural factors influence students' ability to distinguish every day and mathematical meanings of probability terms?

Qualitative thematic analysis identified several recurrent themes explaining semantic interference. First is the linguistic translation and polysemy. Many students struggled with translating the English probability terms into their home languages, which often lacked precise equivalents or introduced additional meanings. Kehinde (SS2) remarked, "In math class, random

means like dice and numbers, but outside it just means something weird or unexpected." This highlights the challenge of parallel semantic systems where students fail to connect formal definitions with everyday language. Second is the cultural beliefs and deterministic frameworks. Cultural narratives about fate, luck, and divine control infused students' interpretations of chance. Nnamdi (SS3) said, "Some things are random because God decides them; that's why people have luck." This spiritual attribution inhibits the accommodation of mathematical randomness, anchoring students in deterministic schemas. Third is the social and moral reasoning on fairness. Students often infused social fairness into the concept of equiprobability. Chika (SS2) noted, "A game is fair if everyone agrees and no one is cheated," blending moral and mathematical notions.

Discussion

This section interprets the key findings of the study in relation to the three research questions, framed within the Framework Theory of Conceptual Change (Vosniadou, 1994; 2013) and informed by sociocultural perspectives on language and cognition (Vygotsky, 1986). The discussion highlights how linguistic ambiguity, cultural beliefs, and cognitive frameworks interact to shape Nigerian secondary school students' understanding of probability vocabulary.

For research question one, the quantitative results revealed moderate overall comprehension of basic probability terms, with higher mastery for certain (72% correct) and much lower accuracy for technical terms like independent (33%) and mutually exclusive (30%). Grade-level progression was significant, indicating that exposure and maturation positively influence vocabulary acquisition, though challenges persist even at the upper secondary level. Gender differences were statistically negligible, suggesting similar struggles across male and female learners. The qualitative data offers critical insights into the nature of these misunderstandings. Students predominantly employed everyday language and culturally grounded interpretations rather than formal probabilistic definitions. For example, the term random was commonly associated with unpredictability, chaos, or spontaneity ("something that just happens anyhow"—Ada, SS1), consistent with findings by Fischbein and Schnarch (1997) and Batanero et al. (2014). Similarly, fairness was more often interpreted through a moral or social lens ("everyone agrees and nobody cheats"—Chika, SS2) than as equiprobable outcomes, corroborating previous research highlighting social justice connotations as obstacles to mathematical fairness comprehension (Gal, 2005). Interpretations of likely reflected subjective belief and judgment rather than quantified probability ("likely means my team will win because they are the best"—Mary, SS2) align with Childers and Viswanathan's (2000) observations of verbal quantifier vagueness. The conceptually complex vocabulary, such as independent and mutually exclusive, was the least understood, with students conflating stochastic independence with causal or social unrelatedness. Musa's (SS2) analogy of "events being independent when they don't know each other" typifies this misinterpretation, similar to Konold's (1989) findings. From a theoretical standpoint, these findings exemplify the dominance of naïve deterministic and social frameworks over probabilistic ones in student reasoning. The progression with grade level indicates increasing, but incomplete, accommodation of formal vocabulary meanings, underscoring the challenge of deeply restructuring conceptual frameworks embedded in everyday experience and language.

For research question two, applying Vosniadou's framework theory, students' responses were categorized to reveal the dominant cognitive positioning towards the target vocabulary. Over half of the participants demonstrated assimilation, fitting new probabilistic vocabulary into pre-existing everyday conceptual systems without significant restructuring. For example, Sola's

explanation of random as “something happens without planning” retains the colloquial notion of spontaneity without internalizing the formal equiprobability concept. This reflects the resistance of established naïve frameworks to replacement (Vosniadou, 1994). A substantial portion exhibited synthetic models, blending formal and informal meanings inconsistently. Tunde’s simultaneous description of random as “every outcome having the same chance" and being “controlled by luck” illustrates the unstable hybrid conceptualization typical of partial accommodation. Only a minority, predominantly among older students, achieved accommodation, restructuring their conceptual frameworks to adopt normative mathematical meanings. Funmi’s articulate explanation of random as “equal chance in a fair die roll” exemplifies this big conceptual change. This cognitive distribution aligns with the complexities of achieving accommodation described by Vosniadou et al. (2001) and the findings of Batanero et al. (2014), who emphasized the challenges posed by entrenched intuitive beliefs. The prevalence of assimilation suggests that vocabulary teaching in probability often leads to surface-level learning unless explicitly linked to conceptual restructuring. This also highlights the importance of recognizing that conceptual change is gradual and nonlinear. Students negotiate meanings across contexts and languages, consistent with Vygotsky’s model of language mediating thought development (1986). The hybrid conceptions indicate the dynamic interplay of linguistic, cultural, and cognitive factors in learning probabilistic language.

For research question three, linguistic challenges emerged as a primary factor contributing to semantic interference. Students often failed to reconcile the dual meanings of probability vocabulary in English and their mother tongues. Kehinde’s comment that random “means dice and numbers in math class, but outside class it just means something weird” encapsulates this dichotomy. This linguistic split mirrors findings by Watson and Moritz (2003) on translation dilemmas in multilingual classrooms. Moreover, the lack of precise equivalents in indigenous languages and the explanatory burden placed on English as a second language intensified cognitive load, impairing concept internalization (Cummins, 2001). Instructional language itself—often informal and unstandardized—added another complexity layer, as vocabulary was inconsistently linked to formal definitions during teaching. Cultural beliefs infused students’ understandings with deterministic and moralistic interpretations. Many participants invoked notions of divine intervention, fate, or luck to explain randomness (“God decides; that is why people have luck”—Nnamdi, SS3), reinforcing non-probabilistic frameworks. These culturally anchored beliefs presented conceptual obstacles to adopting probabilistic thinking. Similarly, fairness was largely conceptualized in social and moral terms, blending equity and justice with the mathematical idea of equiprobability. This conflation reflects Fischbein and Schnarch’s (1997) insights into cultural influences on probability vocabulary and underscores the necessity for culturally sensitive pedagogies. Together, linguistic ambiguity and cultural determinism inhibit clear differentiation between everyday and mathematical meanings and consequently hinder accommodation. Addressing these requires explicit, scaffolded instruction which clarifies linguistic nuances and respectfully integrates cultural narratives, as advocated by Batanero et al. (2016) and Gal (2005).

This paper presents a moment-by-moment analysis of a series of interactions between Kamden, an undergraduate engineering student, and ChatGPT as he solved an unfamiliar statistics problem. Kamden spoke aloud during this episode, which gave us insights about how he interpreted what the task was asking, how he drew upon his prior knowledge to make sense of the task, and his knowledge of ChatGPT. We analyzed each interaction turn between Kamden, the task, and ChatGPT to explain how he connected the expected value of a discrete probability distribution (a concept he did not know) to his knowledge of Riemann sum approximations (a familiar concept). We offer fine-grained insights about how students think and reason mathematically with AI and the role that their own expertise plays in the process.

Keywords: Statistics, Probability, Cognition, Technology

Today's students are expected, even encouraged, to learn with AI tools (OECD, 2026). Yet there is little consensus on what thinking with AI means or looks like in practice, including how we might identify episodes of joint student-AI cognition from instances where students use AI without thinking deeply about the subject-matter they are reasoning about. It seems imperative that the field distinguish between *AI use* to accomplish a task versus *thinking and reasoning with AI* in service of gaining new knowledge, as clarifying this distinction could delineate what human-AI arrangements are conducive for learning. Bastani and colleagues' randomized control trial (2025) illustrated the consequences of AI *using versus thinking*, as students who did math with chatbots experienced a 17% decline in assessment scores after the chatbots were taken away. If students are expected to *use AI* while in school, but do not show robust evidence of *thinking with AI,* this invites larger questions about the purpose of school (Labaree, 1997).

This work attempts to draw such a distinction with empirical data on a statistics task. While video-recording 36 undergraduates who were asked to solve a probability task and use AI if desired, we encountered Kamden, who used ChatGPT to reason about an unknown statistics concept. During roughly 6 minutes of AI-mediated interactions, Kamden linked ideas about the expected value of a discrete probability distribution (previously unknown) to Riemann sum approximations for the area under a function curve. His case is atypical because most other students in the study did not use AI to build new conceptual connections. We present his case to illustrate processes of Kamden's thinking, interactions with ChatGPT, and knowledge that may have helped these conceptual connections to form. We ask: *What knowledge of (a) mathematics and statistics, and (b) AI tools appear to support student thinking in AI-mediated interactions?*

Conceptual Framework

We frame our work within the broader notion of thinking and reasoning as a function of students' own highly interconnected networks of knowledge. Hiebert and Carpenter, who unpacked the notion of what "mathematical understanding" means from a cognitive perspective, suggest that students demonstrate mathematical understanding when facts, concepts, ideas, and procedures are more strongly linked with one another through networks of mental representations (1992, pg. 67). Practically speaking, this suggests that students' mathematical

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

thinking and reasoning should encompass (a) what they understand to be the goal state of the problem, as related to their prior knowledge, and (b) how their prior knowledge is structured and organized in memory to support their mathematical thinking. Chi and Glaser refer to these ideas as *representations* and *schema*, respectively (1985).

An open question is how and to what extent AI-mediation impacts students' representations and schema when they are still building skill and expertise. Since AI tools are designed to procure instantaneous, probabilistically-produced information in response to a student query, we hypothesized that AI-mediated thinking may depend less on students' highly developed schema and more on their ability to monitor their conception of tasks' representations while triangulating them with features of AI-generated reasoning. In short, this means that students should ask, "What facts, procedures, ideas, or concepts is AI giving me, how do I know they are correct, and to what extent do they help me think and reason about what the task is asking?"

To ask such a question, students must develop additional knowledge about AI tools: how they work, what their affordances are, and in what ways they can support or undermine thinking processes. Vérillon and Rabardel refer to such knowledge of tools' affordances as *instrumental genesis* (1995), and Drijvers et al. expanded their conception to include math-specific uses (2010). For instance, a student with high instrumental genesis would know that their TI-84 calculator can accept inputs for a two-sided t-test and calculate the respective *p*-value, but would realize that the TI-84 calculator cannot interpret what the *p*-value means in the context of the statistical test itself. We hypothesize that students must develop instrumental genesis of AI tools, but suggest that developing this expertise may depend more on their awareness of what they prompt and how their prior knowledge is embodied within it.

To date, research on AI-mediated mathematical thinking is emerging and leaves the field with open questions (Pepin et al., 2025; Walkington, 2025). Early empirical work has shown that AI tools can aid students' mathematical thinking in modeling and proof tasks, depending on how students consider and adopt AI solutions (Yoon et al., 2024). In addition to the Bastani et al.'s randomized control trial mentioned earlier (2025), Wu et al. demonstrated that when students reasoned about statistics only with AI tools (and disregarded non-stochastic resources, like class notes), they forfeited epistemic agency because they did not appear to fully understand how information from AI related to their prior knowledge (2025). Relatedly, Schorcht et al. (2024) demonstrated that the contents of students' prompts affected the mathematical quality of AI output, implying that students' ability to articulate their thinking to an AI may impact their subsequent reasoning. We contribute these findings by illustrating how AI-mediated thinking processes unfold with attention to students' knowledge and instrumental genesis.

Methods

Our goals were to examine with immaculate, temporal detail students' thinking and reasoning processes with AI tools. At no point did we require students to use AI. We conducted this study throughout spring 2025, after students at our (large, U.S., mostly-undergraduate) university were given ChatGPT-Edu subscriptions. Our university was an early adopter of AI tools and we wished to learn how students might use them (Delaney et al., 2025).

Study Design

The first author and three graduate research assistants constructed a 90-minute task-based interview (Goldin, 2000). We selected tasks with features that we believed would give students opportunities to decide whether and how to use ChatGPT. They contained algebra, probability, and calculus topics and were designed by curriculum professionals. Here we focus solely on the probability task, named "The ATM Task" by its authors from The College Board (Figure 1).

ATM

A shopping mall has three automated teller machines (ATMs). Because the machines receive heavy use, they sometimes stop working and need to be repaired. Let the random variable X represent the number of ATMs that are working when the mall opens on a randomly selected day. The table shows the probability distribution of X.

X = Number of ATMs working when the mall opens	0	1	2	3
Probability	0.143	0.286	0.429	0.143

Column names and first row of the second table

Day Index	Num. ATM repairs 2023	Num. ATM repairs 2022	Num Mechanics working per day	Daily ATM Usage	Num Working ATMs (beginning of day)
Day 1	2	1	5	43	2

Subtasks

1. What is the probability that at least one ATM is working when the mall opens?
2. On average, how many ATMs will be working on any given day?
3. The data table on the next page contains information about ATMs at the mall. What information from the table do you think was used to create the probability table, and how?
4. What is the probability that all three ATMs are working when the mall opens, given that at least one ATM is working?
5. Given that at least one ATM is working when the mall opens, would the average number of ATMs working on any given day be less than, the same, or greater than the average you found in question 2? Explain.

Figure 1: The ATM Task. Kamden's Analysis Focuses Solely on the Second Question

All researchers held at least three years of collegiate math and statistics teaching experience at the time of this study and were familiar with undergraduates' problem-solving skills. The first author holds a graduate degree in machine learning, experience in clinical interviewing methodologies, and over a decade of experience teaching statistics and mathematics. Our discipline-specific expertise enabled us to conduct this work with high fidelity (Bourke, 2014).

Each interview was conducted as follows: the student was invited into a quiet room with the first author and one graduate research assistant, who led the interview. The interviewer followed a semi-structured protocol designed to inquire about students' uses of AI, and during the tasks, encouraged them to "think aloud" without providing any additional help or hints. For the first 10 minutes, the interviewer asked students about their AI uses and beliefs. Then the student was invited to solve each task (algebra, probability, and calculus, in that order) for up to 20 minutes, and use ChatGPT however they wished. If and when students used ChatGPT, the interview asked why and what they were hoping to learn. After all three tasks were complete, the interviewer debriefed with the student for 10 minutes and paid them $50 for their time. The first author served in a supporting role by video-recording each problem-solving episode, keeping time, and asking clarification questions as needed.

Recruitment, Sample, and Case Selection

We invited undergraduate students who had taken at least one collegiate (or high school equivalent of collegiate) statistics or mathematics course in the past 12 months to participate. It was not a requirement that students needed to have used an AI tool for school before partaking in our study. We recruited students across majors by posting recruitment flyers around the physical campus. Students filled out a brief screening survey, detailing their prior math courses, before we invited them to the study. 36 total students participated in our study from March to May 2025.

Of these 36 participants, we selected a student whom we will refer to as "Kamden" for a fine-grained analysis because his interactions with ChatGPT helped him to begin to connect novel statistics topics to his prior knowledge. This was not the case for the vast majority of other participants. Kamden was a sophomore mechanical engineering major at the time of his interview. He had recently completed Calculus 3 and was currently enrolled in an aerospace course whose description includes "ordinary differential equations, the Laplace Transform, Fourier Series, and linear algebra, with engineering applications" (San Diego State University, n.d.). He also reported that he used AI tools "for just about everything," including mathematics coursework, and described in detail the limitations of AI tools in advanced mathematics due to a lack of training data on those topics. During his interview, Kamden reported that he never took a statistics course (including high school). Thus, Kamden represents a unique case among our sample of relatively high mathematics domain knowledge, relatively high knowledge about AI tools as related to solving mathematics problems in school curricula, and a knowledge gap in probability and statistics, which we appraised from his articulation of prior statistics experience.

Data Collection and Analysis

Kamden was audio, video, and screen-recorded while solving the task, and his ChatGPT log was saved. The video camera was placed behind him to maximize privacy and capture details of his ChatGPT interactions; for instance, where within its output he attended to at any given time. The first author transcribed each task segment first with otter.ai, then by hand, including interactional details about when Kamden interacted with AI between the transcript and his ChatGPT log (Jordan & Henderson, 1995). These types of details helped us to identify which segments of Kamden's episode were enacted with AI-mediation.

The first author and a graduate student who was not one of the three study designers analyzed Kamden's case, which began around 57 seconds into the ATM task and lasted approximately six minutes. We use microanalytic knowledge analysis to examine moment-by-moment what Kamden appeared to know (diSessa et al., 2016). Knowledge analysis stems from the Piagetian tradition of knowledge construction (Piaget, 1972), is context-specific, treats knowledge as a medium that can take on diverse (and sometimes unstable) forms, and requires nuanced interpretation. Our microanalytic episode was selected from the larger corpus for a short time scale where Kamden's prior knowledge about calculus may have been cued by features of the ATM task and the ChatGPT environment/interactions (Sherin, 2001). In analyzing this episode, our goal was to generate ideas about how Kamden's interactions with ChatGPT impacted his knowledge of the ATM problem representation and how this knowledge was generated.

The first author segmented the episode into phases by ChatGPT prompts or interviewer questions that elicited additional clarification from Kamden. Then each researcher analyzed Kamden's interactions individually and iteratively. While watching, re-watching, and memoing about the episode, researchers observed how Kamden's problem representation changed over time, how his schema appeared to support his problem representation, and how his interactions with ChatGPT's information appeared to influence his representation, including his evolving conceptions about what the "average" means in a discrete probability distribution. We also hypothesized connections between elements of Kamden's knowledge at various time points via sketched graphs. Then both researchers met and discussed our interpretations of Kamden's evolving knowledge. We referred back to transcripts and collected artifacts until we reached agreement on what Kamden appeared to know, grounded in evidence of what he stated aloud. For instance, we needed to affirm in several cases what Kamden knew about the meaning of probability distributions, as opposed to instances where he was simply re-reading portions of the task aloud. We discussed until we reached intersubjective agreement about Kamden's representations and schema (Krippendorff, 2018). We reduced the data to findings that highlight interactions with and without ChatGPT that appeared to influence changes in his knowledge.

Findings

We present the findings by phases to present a descriptive narrative of how Kamden's new statistics knowledge emerged and the interactions with ChatGPT that may have cued it.

Phase 1: Initial Representation

Kamden read the second ATM task question and almost immediately stated, "I don't know what question to ask, so I'm just going to ask ChatGPT." Asking ChatGPT, in this context, meant typing the question into the prompt and including all information from the probability table, which Kamden explained aloud. Figure 2 shows his prompt and ChatGPT's response. At this point, it was not yet clear to us what Kamden wanted to learn from ChatGPT, as his prompt contained only the task and its corresponding information, and omitted language that would have

signaled a request for a particular form of response. His spoken utterance suggests that he has not yet formed an initial representation ("I don't know what question to ask").

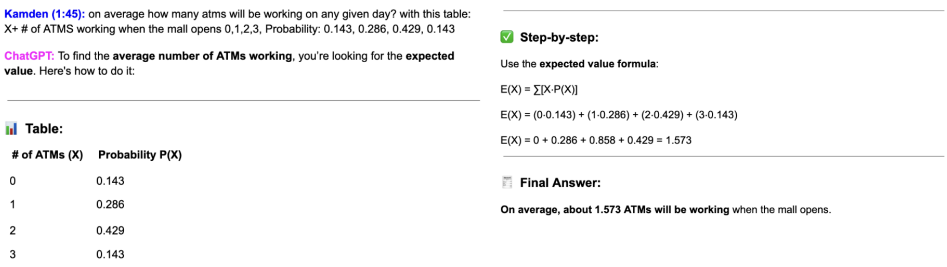

Figure 2: Kamden's First ChatGPT Interaction

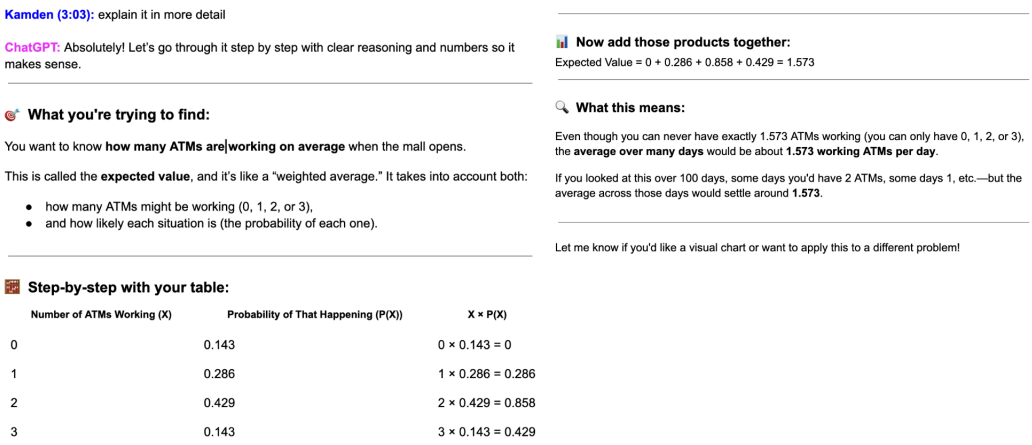
Phase 2: Representation After First ChatGPT Prompt

We observed that ChatGPT's output immediately inferred a representation: "to find the average number of ATMs working, you're looking for the expected value." It further provided a tabular and symbolic schema for calculating the expected value. Kamden, interestingly, did not attend to its representation, nor did he mention "expected value" at any point. He did notice the table and appeared to connect it to prior knowledge about *x*-*y* table representations: "My probability's the *y*-axis, the number of ATMs is the *x*-axis, so from the table I got that. And then I figured it was an average of them, or some sort of average … so the answer is 1.573."



Some sort of average suggested that Kamden may have held a prior belief about what "average" is, such as the arithmetic mean as it is often presented to middle school students as a measure of centrality. Furthermore, it suggests that ChatGPT's table did not present "average" as Kamden may have known it, because he does not associate it with a centering feature within the table, or more broadly, any mathematical characteristic of averages. At this point, Kamden has processed ChatGPT's representation, read information that ChatGPT has (stochastically) determined to be associated with his query, and is connecting it to ideas that he remembers.

Phase 3: Representation After Second ChatGPT Prompt

Kamden then realizes that he still does not understand the question and states: "I'll just ask [ChatGPT] to explain it … honestly just what the question is asking." "What the question is asking" (in other words, a more specific request for a representation) is what Kamden means when he says "explain it in more detail" in his second prompt (Figure 3).

Again, Kamden appeared to ignore the portions of ChatGPT's output that explained the expected value concept ("the expected value [is] like a "weighted average") and instead focused on the table and computations associated with the table. He reacted to the information aloud:

Kamden:	There's a specific probability for each one, and there's a specific number of ATMs for each *x*-axis. It just did the computations … that's (gestures to screen) when there's zero, that's the probability that they're working when it's one. That's the probability that they're working when it's two. That's the probability that it's working when it's three. So, it just did some sort of function, and it solved it, and that's how many ATMs there would be.
Lead Int.:	Have you seen this function before?
Kamden:	I mean, it's just a sum of the *x* times the *y*. So, it's the number of ATMs times the probability of there being an ATM working, and then just added them all together to get the total number of ATMs.

Kamden (3:03): explain it in more detail

ChatGPT: Absolutely! Let's go through it step by step with clear reasoning and numbers so it makes sense.

What you're trying to find:

You want to know **how many ATMs are working on average** when the mall opens.

This is called the **expected value**, and it's like a "weighted average." It takes into account both:

- how many ATMs might be working (0, 1, 2, or 3),
- and how likely each situation is (the probability of each one).

Step-by-step with your table:

Number of ATMs Working (X)	Probability of That Happening (P(X))	X × P(X)
0	0.143	0 × 0.143 = 0
1	0.286	1 × 0.286 = 0.286
2	0.429	2 × 0.429 = 0.858
3	0.143	3 × 0.143 = 0.429

Now add those products together:

Expected Value = 0 + 0.286 + 0.858 + 0.429 = 1.573

What this means:

Even though you can never have exactly 1.573 ATMs working (you can only have 0, 1, 2, or 3), the **average over many days** would be about **1.573 working ATMs per day**.

If you looked at this over 100 days, some days you'd have 2 ATMs, some days 1, etc.—but the average across those days would settle around **1.573**.

Let me know if you'd like a visual chart or want to apply this to a different problem!

Figure 3: Kamden's Second ChatGPT Interaction

In making sense of this information, Kamden connected how the value of 1.573 was obtained by viewing the $X * P(X)$ calculations per row in the output. He attributed these calculations to ChatGPT "doing some sort of function." We note that there was no function given in this AI interaction and that Kamden associated the series of calculations with function behavior either in the prior ChatGPT interaction or his prior knowledge. He interpreted the function in the context of the problem, however it was still not apparent that Kamden knew how the "total number of ATMs" was related to the concept of average or centrality. By this point, Kamden had associated a particular algorithm for computing "some sort of average" with his prior knowledge of bivariate relationships and function relationships. It was not yet clear if he knew what the task was asking, why the computation made sense, or how it was related to the notion of "average."

Phase 4: Clarifying the Meaning of "Average"

Realizing this discrepancy, the supporting interviewer (Supporting Int.) engaged in the following dialogue with Kamden where he appeared to make connections between "average" and his prior knowledge. This time, he referred to the probability table in the task while making the connections:

Supporting Int.: Can you say…why that explanation makes sense?
Kamden: The answer makes sense that there would be 1.573 [ATMs]. Because, if we're only looking at these four specific [columns of data] … half of the data is over two, half of the data is under two. The average was 1.573 because the probability of it not working goes up with two [to 0.429].

This clarified the value of 1.573 as the approximate "center" of the data table for Kamden (relating to the centering aspect of "average") and may have explained why he trusted the value 1.573 even though he did not appear to know why the expected value formula yielded "some sort of average." The supporting interviewer pressed once more to attempt to understand how Kamden made sense of this:

Supporting Int.: How did you come to trust ChatGPT's expected value formula … because I think you'd said you have never taken a statistics course?
Kamden: No yeah, it was new. But I've seen stuff like that, the sum part … so calculating the average looked similar to a right Riemann sum or left

> Riemann sum … so the number of ATMs times the probability and adding those together to get a total average probability. So that made sense.

At last, we observed that Kamden's mental model of average in this context combines his knowledge of bivariate relationships, functions, calculations of and with Riemann sums, and what Riemann sums represent (a "total" approximation). Kamden explained that he linked ChatGPT's calculations for "some sort of average" to calculations for how right or left Riemann sums are calculated. Both contain computations of the form *quantity 1 multiplied by quantity 2* repeated over a fixed interval. This in turn led Kamden to construct a notion of "total average probability" (his phrasing) akin to approximations through Riemann sums as an accumulation of a function. More specifically, Kamden's task representation is a conception of "total average probability" as related to algebraic and geometric ideas of accumulation over an interval, and measures of center as the "midpoint" between the interval of x-values in the given probability table. ChatGPT appeared to support his conception by illustrating how "average" calculations over this interval could be constructed and how those calculations were related to mathematical ideas (e.g., summation functions and bivariate relations) that were, by chance, part of his schema.

Discussion

Our analysis presents an unfolding of Kamden's mathematical thinking with ChatGPT about a statistical concept that he did not appear to have prior knowledge about before the ATM task. By the end, Kamden connected the expected value of a discrete probability distribution ("some sort of average") to his prior knowledge of summations, functions, bivariate relationships, and calculus approximations. We attempt to model changes in his knowledge network in Figure 4, noting that our representation is naturally limited by its inferential and interpretive properties.

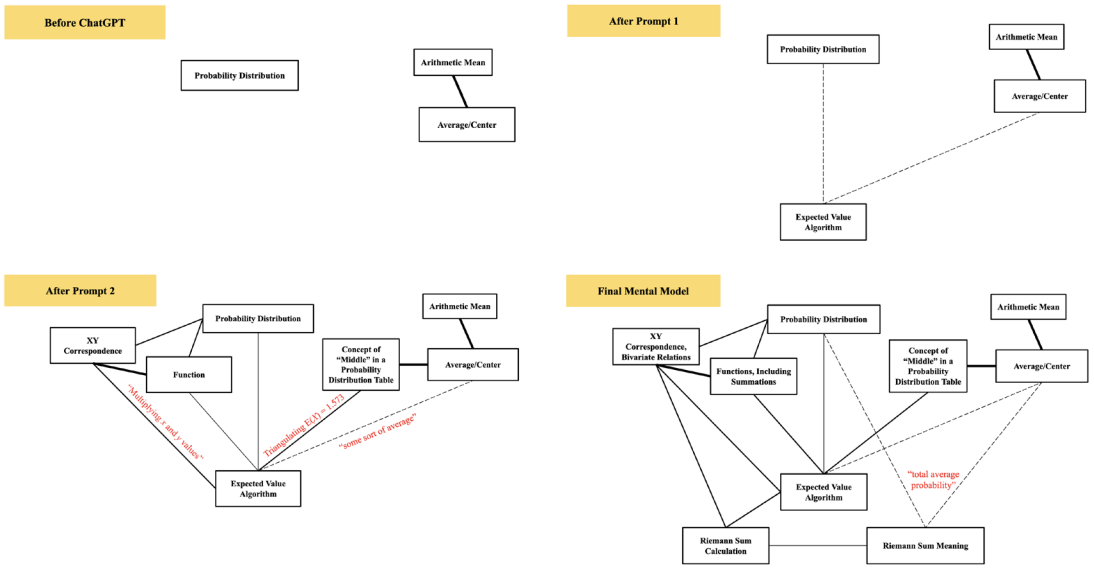


Figure 4: Hypothesis of Kamden's Evolving Knowledge During This Episode

We discuss features of Kamden's AI interactions that may interest education researchers and teachers. First, Kamden spent much of the episode iteratively reasoning about the task representation. Upon reading ChatGPT's first output, he made a few conceptual connections to

bivariate distributions and functions, but these connections alone were not enough for him to make an assessment about the task's goal. Rather, he knew that he did not have enough prior knowledge about averages derived from a probability table, and prompted AI again. This interaction combined his knowledge of mathematics and statistics, showed evidence of progress monitoring, and revealed his instrumental genesis about AI tools, because he appeared to know that there was no discernable disadvantage to re-prompting ChatGPT for a different explanation.

Second, we observe that Kamden's progress monitoring of the task representation had limitations from the perspective of the interviewers, who were mathematics teachers. While Kamden stated, "it makes sense" after ChatGPT's second output (Figure 3), the interviewer was unclear *what* made sense because they had not yet heard evidence of how Kamden connected "average" to his prior knowledge. It was only after Phase 4 that it became apparent how Kamden organized "average" with his schema of Riemann sums: he associated the center of an accumulated probability with the idea of accumulated area of a function, as approximated by rectangle areas over a fixed interval, which he appeared to infer from the $X * P(X)$ calculations given by ChatGPT. We took this to be a mathematically legitimate construction, although it likely shares instability properties described by diSessa et al. (2016).

It is unclear if Kamden would have reached his conceptual connection without the interviewer. He appeared ready to move on before the interviewer requested him to re-articulate what made sense. The substance of the interviewer's questioning suggests that Kamden's knowledge in Phase 4 was co-constructed between himself and the interviewer (Koichu & Harel, 2007). This points toward a broader finding that students' own progress monitoring and metacognition (Flavell, 1979) may only extend so far in tasks containing unfamiliar mathematics or statistics. Because Kamden may have had less of a sense about how to organize the expected value "average" in his schema of algebraically-cued ideas, he did not appear to know where or how to organize this average within his mathematical knowledge network (Hiebert & Carpenter, 1992), and likely still does not understand this "average" in a statistically-rigorous sense.

We view this finding as important for teachers. It reveals that even a student who has taken advanced mathematics courses and maintains (relatively) high instrumental genesis of AI can struggle to independently configure new statistics and/or mathematics ideas into their schema. Part of this struggle may be a function of human attention, as ChatGPT (Phase 3) gave output that explained a notion of "weighted average" that Kamden did not attend to, which could have aided him. Research on high-quality math teaching shows that teachers direct students' attention toward mathematically salient concepts, procedures, and connections, and orchestrate instruction that makes mathematical connections stronger (Stein et al., 2008). Our study shows that while AI tools can jumpstart the process of building mathematics connections, students may not exhibit follow-up behaviors to strengthen connections on their own (or at least, not in the short-term).

There are limitations that should impact how the results are interpreted. This study took place in a clinical setting, and Kamden's interactions with AI tools may differ in classrooms, where his learning goals and orientations toward mathematics tasks are likely different. Yet this setting was necessary in order for Kamden to explain his uses of ChatGPT, and as such, we view our study ecology as a necessary tradeoff for what we wanted to learn. Additionally, the remaining 35 students in our sample did not tend to think and reason as deeply as Kamden did with ChatGPT. We encourage the reader to view his interactions with AI as one instantiation of possible AI-mediated reasoning, not as what most students typically do when they use AI for statistics or mathematics. This also suggests that much more research is needed to illustrate the range of possibilities that may occur during thinking processes between students and intelligent agents.

USING PEIRCE'S CASE-RULE-RESULT FRAMEWORK TO CHARACTERIZE STUDENTS' REASONING ABOUT SAMPLING DISTRIBUTIONS

Claire Miller
University of Georgia
clairemiller@uga.edu

I used Charles S. Peirce's three classic forms of inferential reasoning—deduction, induction, and abduction—defined by case, rule, and result to examine 11 undergraduate students' understanding of sampling distributions. In this paper, I report on a subset of these findings. During one clinical interview, I engaged each student in a task designed to investigate their reasoning when estimating an unknown population parameter. Although all three forms of reasoning were present, abductive reasoning was particularly useful in drawing conclusions from sample data to the population with an unknown parameter.

Keywords: Data Analysis and Statistics, Cognition, Undergraduate Education

Data are everywhere. Developing statistical reasoning is essential for students to evaluate data-based claims and become well-informed citizens (Bargagliotti et al., 2020). A critical component of statistical reasoning is inferential reasoning, or drawing conclusions from data. Described as a "fundamental skill for participation in a global, technological, and data-driven society" (Noll & Hancock, 2015, p. 362), inferential reasoning involves multiple ideas, such as repeated sampling, variability, and randomness. Understanding these ideas is important for improving students' statistical literacy and productive citizenship (Franklin et al., 2007). Despite its importance, research indicates that reasoning inferentially is complex for students (e.g., Sotos et al., 2007). Although many students can perform calculations for formal statistical inference procedures, they have difficulty understanding the underlying logic (Chance et al., 2004). Part of this difficulty stems from the complex and abstract nature of sampling distributions, which requires coordinating multiple ideas such as sample, population, distribution, and variability (Noll & Shaughnessy, 2012; Saldanha & Thompson, 2002; 2007). Furthermore, statistical reasoning requires reasoning with uncertainty. This type of reasoning differs from students' many and varied experiences in mathematics classes, which include an emphasis on deterministic reasoning.

Theoretical Framework

Definitions of reasoning include some process for arriving at a conclusion or making an inference (National Council of Teachers of Mathematics, 2009). Deduction, induction, and abduction are three classic forms of inferential reasoning. I adopt definitions from Peirce (1878) and others (e.g., Reid & Knipping, 2010). *Deductive reasoning* is the process of drawing logically valid conclusions based on stated assumptions or rules and is thought to be the only form of reasoning that establishes a conclusion with certainty. *Inductive reasoning* involves generalizing a rule from several observations. *Abductive reasoning* starts with an observation and involves hypothesizing what rule might lead to that particular observation. Peirce (1878) defined deduction, induction, and abduction in terms of a triadic structure involving a *case*, *rule*, and *result* that are linked in a particular order. Interpreting Peirce's definitions, Reid & Knipping (2010) defined a *case* as a specific observation that a condition holds. A condition describes an attribute of something, or a relation between things. A *rule* is a general proposition that states that if one condition occurs then another one will also occur. A *result* is a specific observation,

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

similar to a case, but referring to a condition that depends on another condition linked to it by a rule. The order in which one links a case, rule, and result determines the kind of inference needed to gain more knowledge about the situation. In deductive reasoning, a rule and a case conclude a result. In inductive reasoning, a case and a result (or often, many cases and many results) lead to a rule. In abductive reasoning, a result and a rule infer a case.

Reasoning about data involves reasoning under uncertainty. This kind of reasoning is different from what is expected and highlighted in mathematics, such as deductive reasoning and proof. Although deduction, induction, and abduction are seen in both mathematics and statistics, deduction is privileged in mathematics whereas induction and abduction should be emphasized in statistics because these forms of reasoning include uncertain conclusions. More specifically, reasoning abductively is a productive way to reason when drawing conclusions from sample data because abductive reasoning shares aspects of inferential reasoning. Abductive reasoning is the inference of a case from a rule and result: We start with an initial observation, or result. This result could be explained by the supposition that it is a case of some general rule. Therefore, we adopt that supposition (Peirce, 1878). Similarly, in statistical inference, we start with the outcome of a sample (result). By considering the probability of the sample outcome under multiple hypothetical parameters, we conclude the sample outcome could be explained by (is a case of) the supposition that it was drawn from a population whose parameter is equal to p (general rule). Therefore, we adopt that supposition. This paper reports on a subset of findings from a larger project in which I investigated novice statistics students' understanding of sampling distributions. For this paper, I studied the research question: When given a population with an unknown parameter, what forms of reasoning (i.e., deduction, induction, and abduction) do students employ when making inferences from one sample outcome to the population from which it was drawn, and what do these forms of reasoning reveal about their understanding of sampling distributions?

Methods

Participants for the larger study were 11 undergraduate students who had recently completed an introductory statistics course. I engaged each student in two clinical interviews, each 60-75 minutes in length, in which students worked through a series of statistical tasks related to sampling distributions. The context of the tasks across both interviews was about the proportion of intended business majors at two large universities: North University's website states that 20% of their undergraduate students are intended business majors while South University's website does not have this information posted. In the first interview, students reasoned about sample outcomes from North University, a population with a known parameter. They made predictions for sample outcomes, physically drew samples from a large box of beads with proportions corresponding to the population of interest, simulated drawing many samples using a web-based applet (Rossman & Chance, 2021), and continually updated their estimates of sampling variability. In the second interview, students reasoned about the unknown parameter at South University. They drew one sample from a large box of beads that modeled the South University context, made an initial prediction for the unknown parameter, tested and refined one or more predictions using the web-based applet, and provided a range of values they believed captured the unknown parameter. This paper reports on data collected from the second interview.

After checking and timestamping interview transcripts against audio and video recordings, I adapted Simon's (2019) three-level approach to analyzing qualitative data. In the first level, I analyzed the transcripts line-by-line and identified segments of data in which students provided an explanation or a justification. Taking a convergent approach (Clement, 2000) in the second

level of analysis, I applied Peirce's (1878) case-rule-result framework to each segment to infer the form of reasoning students used. This involved identifying what the student used as a rule and how they applied the rule to a case (deductive reasoning), developed the rule from multiple cases (inductive reasoning), or hypothesized a rule to explain a case (abductive reasoning). In the third level of analysis, I identified emergent themes that provided additional insight into students' understanding of sampling distributions beyond the three broader forms of reasoning.

Results

All three forms of reasoning were evident across the participant pool: three students reasoned abductively, one student reasoned inductively, and five students reasoned deductively. Two students did not show evidence of these three broader forms of reasoning. Due to limited space, the idiosyncratic nature of these two students' reasoning, and the focus of the research question, I describe and compare the reasoning of a subset of nine participants who engaged in abductive, inductive, and deductive reasoning. For complete results, see Miller (2024).

Nine students engaged in repeated patterns of reasoning as they engaged with the box of beads and the web-based applet. Although students were tasked with estimating the unknown population parameter based on one sample they drew from the large box of beads, not all students used this information. Seven students repeatedly referred to the outcome of their single sample as they engaged with the task. Of these seven students, three reasoned abductively and four reasoned deductively. Other than making an initial prediction for the unknown population parameter, two of the nine students did not use the information from their single sample to estimate the unknown parameter. Of these two students, one reasoned deductively and the other reasoned inductively. Beyond these three broader forms, I identified four components that were important in understanding differences in students' reasoning:

1. Students related one or more sampling distributions to a hypothetical population;
2. Students assessed the plausibility of one or more values for the unknown parameter by considering the likelihood of one sample outcome;
3. Students assessed the plausibility of multiple values for the unknown parameter by considering visual characteristics of the graph (e.g., shape, highest peak) of one or more sampling distributions;
4. Students provided a range of values for the unknown population parameter based on the outcome of multiple random samples.

I first describe and compare the abductive and deductive reasoning of the seven students who repeatedly used their sample outcome in their reasoning. Then I describe the deductive and inductive reasoning of the two students who did not use the result of their sample to determine their range of values for the unknown parameter. Throughout both sections, I support the major findings by identifying what the broader forms of reasoning and the more nuanced differences in reasoning revealed across the student pool.

Drawing Inferences About a Population Using the Result of One Random Sample

Seven students used the likelihood of their sample outcome to assess the plausibility of multiple values for the population parameter (Component 2). However, the form of reasoning the students employed revealed a subtle yet critical component of their understanding of sampling distribution. Those who reasoned abductively showed evidence of coordinating at least two levels of distribution—population distribution and sampling distribution—indicating they understood that each sampling distribution they constructed represented a collection of sample

outcomes that could have been produced by some hypothetical population (Component 1). Those who reasoned deductively showed evidence of understanding that each sampling distribution represented a collection of sample outcomes, but they did not relate the collection to the population that could have produced the collection—a critical understanding in drawing inferences from sample data to the population from which it was drawn.

Abducing plausible values for the unknown population parameter. Three students related one or more sampling distributions that they constructed using the applet to a hypothetical population that could have produced the collection of samples outcomes (Component 1). These students abduced a range of values based on the likelihood of the outcome of their one random sample that they drew from the box of beads that modeled the South University context. They repeatedly predicted and tested multiple values for the unknown parameter and assessed the plausibility of each value by considering how often their sample occurred in the many samples they drew using the web-based applet (Component 2). Each time they determined that a hypothesized value was plausible, they abduced a case from a result and a rule. Starting with their one sample outcome (result), they hypothesized a value for the unknown population parameter, then constructed a sampling distribution with the probability of success equal to the hypothesized value and drew many samples. Because their sample outcome was likely to have occurred under the hypothesized value (rule), they abduced that their sample could have been drawn from a population whose parameter was equal to the hypothesized value (case).

For example, when Eric (pseudonym) tested his prediction of 40% for the unknown population parameter, he used the applet to simulate 500 random samples of size 100 using a probability of success of 0.4. Figure 1 shows the results of his simulation. He explained that the 40% represented "the assumption that if South University had their proportion online…that proportion is 40%," thus relating the sampling distribution he constructed to a hypothetical population whose true parameter was equal to 40% (Component 1). To assess the plausibility of his prediction, he considered the likelihood of his sample outcome of 50% (Component 2) under this assumption. He said, "If you say it's 40, then 50 could be a possibility," pointed to a sample outcome of 50 on the dot plot, and said, "So we could say, oh, that one [sample] that I drew was that one." Given his sample outcome of 50% (result), Eric assessed the likelihood of his sample outcome, determining his sample outcome "could be a possibility" if the true parameter were 40% (rule). He abduced that his sample outcome could have come from a population whose true parameter was 40% (case) and included 40% in his range of values for the unknown parameter. Eric, Lorraine, and Lyla repeatedly used the applet in this way to abduce multiple values that were plausible for the true percentage of undergraduates at South University who were intended business majors, ultimately providing a range of plausible values for the unknown parameter.

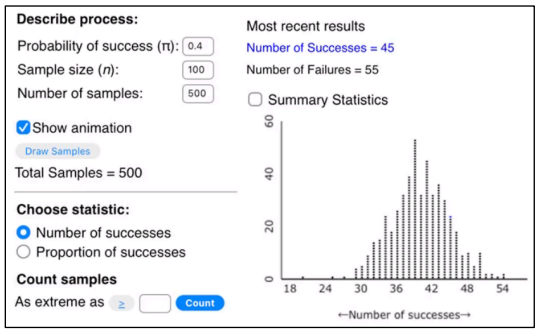

Figure 1: The Results of Eric's Simulation When Testing 40%

The conclusion of this abductive inference is that the random sample these students drew could have been drawn from a population with some parameter, *p*. Without connecting a collection of sample outcomes to the population from which they were drawn, this conclusion is not possible. Without this connection, considering the likelihood of the outcome of the one sample drawn from the box of beads can be used as a procedure to deduce a range of values for the unknown population parameter. This was the case for Tami, Tyra, Mindy, and Corrina.

Deducing plausible values for the unknown population parameter. Four students used the likelihood of their sample outcome to assess the plausibility of multiple values for the unknown parameter (Component 2) and applied a general rule (rule) to each of their predictions for the unknown parameter (case) to deduce whether they should include the prediction in their final range of plausible values (result). These students reasoned that if their sample outcome occurred often when the probability of success was equal to *p*, then *p* should be included in their range of values, without connecting the collection of sample outcomes to a population whose parameter is equal to *p*. This connection is the subtle yet critical distinction between an abductive inference and deductive inference in this context.

Corrina's reasoning is representative of the group. When testing her prediction of 40%, Corrina considered the likelihood of her sample outcome of 51. She said, "It's kind of on the higher end. It's not as likely, but it totally could happen" and included 40% in her range at the end of Task D (see
Figure 2a). When she tested 60%, she said, "Yeah, so that 51, again, is kind of on the lower end, but still likely, so I think it could be 60" (see
Figure 2b) and, again, included 60% in her final range of 38% to 62% for the unknown parameter.

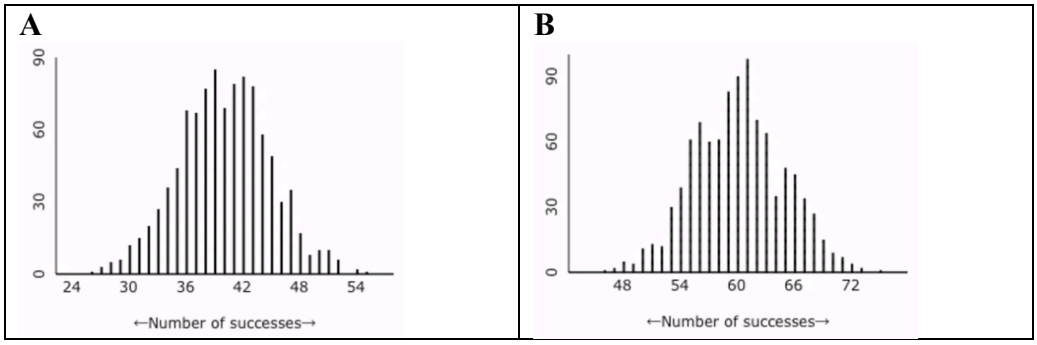

Figure 2: The Results of Corrina's Simulations When Testing 40% and 60%

Corrina applied a general rule to each of her predictions to deduce whether she should include the prediction in her range of values for the unknown parameter at South University: If my sample outcome occurred in a large collection of outcomes when the probability of success is equal to *p*, then *p* should be included in my range of values. She applied her rule to her prediction of 40% and reasoned that because her sample outcome of 51 "could totally happen" when the probability of success was equal to 40% (case), then 40% was a plausible value for the unknown parameter (result). Similarly, because her sample outcome of 51 was "on the lower end, but still likely" when the probability of success was 60% (case), then 60% was a plausible value for the unknown parameter (result).

Drawing Inferences About a Population Without Using the Result of One Random Sample

Other than in their initial prediction for the unknown parameter, two students did not use the result of their one sample to determine a range of values for the unknown parameter. Instead, Julie used the shape and highest peak of each sampling distribution she constructed using the web-based applet (Component 3) and Jess used the results of five random samples she drew from the box of beads (Component 4). Although both students understood that random samples will produce outcomes that vary from the population parameter, they did not apply this understanding to a new context—one in which the parameter was unknown—to determine the likelihood of their sample outcome under multiple hypothesized values for the unknown parameter.

Using visual characteristics of a graph: Julie's deductive reasoning. Julie estimated the unknown parameter by considering visual characteristics of the dot plots she constructed using the applet (Component 3). She constructed multiple sampling distributions, identified the "highest peak," and included her prediction in her final range if the "highest peak" was close to her predicted value. Julie's initial prediction for the unknown parameter was 55% because it was close to her sample outcome of 60%. To test her initial prediction, Julie input 0.55 as the probability of success and drew 525 samples (see Figure 3). After asking Julie if any of the samples she drew resulted in samples like the one she drew from the box of beads, she said, "I definitely had at least five were at 0.6" and explained this meant her initial prediction of 55% was "more accurate" than her sample outcome because there were "more near 0.55 than 0.6."

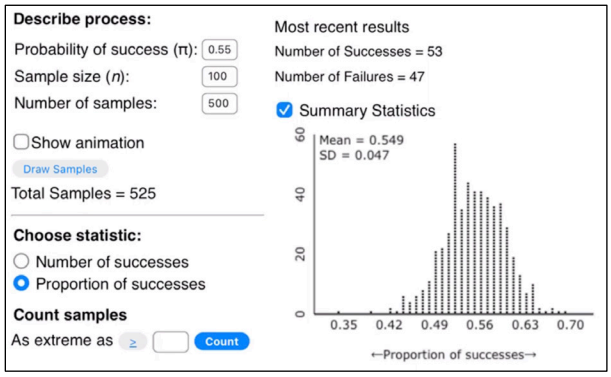

Figure 3: The Results of Julie's Simulation When Testing 55%

Because there were more sample outcomes that resulted in 0.55 than 0.6, Julie reasoned that her initial prediction of 0.55 was a better estimate for the unknown parameter than her sample result of 0.6. This is evidence she may have viewed the sampling distribution as a collection of sample outcomes from the actual South University. As I tried to understand Julie's thinking, I asked her to interpret the 0.55 she input in the applet. She explained, "So, essentially if the university had reported the statistic and how many they believed were intended business majors, that's what the 0.55 is. If they had reported it, but right now it's what my prediction was." During the interview, I interpreted Julie's explanation to mean she understood she used the applet to draw 525 samples from South University, *if* South University's true percentage of intended business majors was 55%. However, only through retrospective analysis did I gain a different understanding of Julie's thinking; I hypothesize she viewed each sampling distribution she constructed as a collection of sample outcomes from the actual South University. This would explain why Julie based her subsequent predictions on the mode, or what she called the "highest peak," of one or more

distributions she constructed. For example, after Julie tested her initial prediction of 55%, she chose to test 52%, which was the mode of the distribution shown in Figure 3. Julie tested multiple predictions, such as 52%, 60%, and 47%, among others. Each time she input a new prediction in the applet and drew 500 or more samples, she identified the mode(s) of the distribution and used this information to make future predictions and to determine whether she should include her predicted value in her interval estimate for the unknown parameter. Julie ultimately provided a range of 47% to 63% and summarized her process and justified her confidence by explaining, "Every time we do in the range of 47 to 63, it starts to centralize around that number. So that's why I am pretty confident it would be in that range."

Julie's repeated reasoning indicates she deduced her range of values from a rule involving the mode, or "highest peak," of each distribution: If the mode is approximately equal to the probability of success, p, then p is a good estimate for the true parameter (rule). When testing her prediction of 47%, she identified 0.47 as being "tied for the highest" (case), so she deduced that 47% should be included in her range (result). Based on her understanding of how samples vary from the population parameter, if Julie viewed each sampling distribution as a collection of sample outcomes from South University, she would identify the center of the distribution as the parameter. Throughout her predicting and testing, Julie identified the outcome with the "highest peak" as a plausible value for the true parameter, supporting my hypothesis that she viewed each sampling distribution she constructed as a collection of sample outcomes from the actual South University, rather than from a hypothetical population whose parameter was equal to the probability of success she input.

Using the result of multiple samples: Jess's inductive reasoning. Like Julie, Jess initially identified the mode of each distribution and used this information to make future predictions. However, Jess was perturbed when she noticed that each time she changed the probability of success in the applet, the center of the distribution shifted. She said,

> I think in my head, the probability of success, it's like whatever number I'm going to change it to, it's going to kind of situate it around that. So, if I put it to 0.7, it's going to shift it to 0.7…Because I'm telling it there's a 70% chance of success, therefore it's more likely to be situated around 70…So, I guess thinking about that now, I feel like maybe there is a way using this graph to determine the proper prediction, but I wouldn't know how based on just one thing (points to her sample) because I'm telling it this is the prediction or this is how many business majors there are at the school.

Jess explained multiple times that she was not confident in any value she tested using the applet and said, "I think for me to give a range and feel more confident, I would want to scoop out a couple more and see truly how many I get each time." Although this was not the intent of the task, I allowed Jess to draw more samples. Jess drew five random samples from the box of beads (cases), observed that her sample outcomes were in the "high fifties and low sixties" (results), so she induced a range of 57 to 62 for the unknown parameter at South University (rule). Jess was the only student to draw multiple samples from the box of beads and use these sample outcomes to induce a range of values she thought was plausible for the unknown population parameter. Reasoning inductively in this way is productive, but unrealistic. In other words, Jess could easily draw multiple samples and estimate where they clustered because the samples she drew came from a box of beads representing South University undergraduates. However, it is not feasible or cost-effective to draw multiple samples from a population of interest to estimate the unknown parameter.

Discussion

When given a population with an unknown parameter, students employed all three forms of reasoning when making inferences from one sample outcome to the population from which it was drawn. However, students who reasoned abductively showed evidence of having a more sophisticated and flexible understanding of sampling distributions than those who reasoned deductively or inductively.

I identified a subtle yet critical distinction in students' reasoning across the two groups who used the likelihood of a sample outcome to determine a range of plausible values. Although the reasoning in both groups initially appeared similar, additional analysis and comparisons of students' explanations and justifications revealed that students who reasoned abductively explicitly hypothesized multiple populations that could have produced their sample outcome. These three students reasoned about the multi-tiered repeated sampling process (Saldanha & Thompson, 2002) and coordinated at least two levels of distribution—population distribution and sampling distribution. In contrast, students who reasoned deductively included the likelihood of their sample outcome in their rule for determining whether to include a particular prediction in their range of values for the unknown parameter but did not connect a hypothetical population with the resulting sampling distribution.

Following Peirce's (1878) definitions, I argue that statistical inference is an abductive process: concluding the sample (result) could have been drawn from (is a case of) a population with some parameter *p* (rule). This requires the student to connect a collection of sample outcomes back to a hypothetical population. Only those who reasoned abductively made this connection explicit, treating each applet-generated sampling distribution as a collection of outcomes from a population with a specific hypothetical parameter. This result brings up an important question about the causal mechanism between coordinating multiple levels of distribution and reasoning abductively: Were students able to reason abductively *because* they understood the relationship between the hypothetical population and the sampling distribution, or did they understand the relationship between the hypothetical population and the sampling distribution *because* they reasoned abductively? My initial hypothesis was that these students were able to reason in this way because they understood the relationship between the hypothetical population and the sampling distribution. However, Lyla's final remarks suggest the latter. She said,

> That was just really cool. I don't know. It was cool to go backwards from, you just know when you take stat, it's like, oh, we have this confidence that this number is going to fall in this population because of blah, blah, blah, blah. But working backwards shows the logic behind it even more. I thought it made sense to me before, it made perfect sense, our rationale for drawing these conclusions. But going backwards, it's another level of understanding.

Lyla described the process of "working backwards" from a sample to a population as "another level of understanding" compared to the traditional calculation-based procedures of confidence intervals taught in introductory statistics courses like the one she had recently taken. Her reflection on her own understanding suggests that tasks requiring students to repeatedly predict and test parameters support the complex coordination of different levels of distribution.

Surprisingly, not all students used their sample outcome to inform their inferences. These students appeared to view the applet-generated sampling distributions as collections of outcomes from the *actual* population rather than a *hypothetical* one. Although they understood that samples vary and cluster around the population parameter, they did not apply this understanding to a

context where the parameter was unknown. They likely interpreted the probability entered into the applet as a "true" value rather than a testable hypothesis. It is possible that these students' existing meanings did not enable them to productively engage with the applet to further their understanding. This suggests that while simulation tools are intended to support students in visualizing abstract concepts (e.g., Garfield et al., 2012; Saldanha & Thompson, 2014), they do not automatically produce the intended meanings. More research is needed to understand how students' existing meanings influence their engagement with simulation tools.

MAPPING EQUITY: THE IMPACT OF PLACE-BASED DATA USE IN SYSTEMS ENGINEERING CLASSROOMS

Ian Thacker
University of Texas, San Antonio, USA
ian.thacker@utsa.edu

Francisco Benita
Tecnologico de Monterrey, Monterrey, MX
francisco_benita@tec.mx

Many entrepreneurship and systems-engineering programs prioritize profit over social responsibility when teaching location-based decision-making. This study explored means of fostering data-informed, other-oriented purpose and motivation among systems-engineering undergraduates using place-based data visualizations. Industrial and Systems Engineering students in Mexico (N = 63) participated in a quasi-experimental study with a pre-post-followup control group design. Participants in the treatment classroom engaged with geospatial data visualization software to select a location for a hypothetical restaurant in ways that balanced profit with social responsibility for providing accessible services to the community. Compared to a business-as-usual comparison classroom, students demonstrated lower levels of self-oriented motives and cost perceptions, but shared that the technology was difficult to use.

Keywords: Data Literacy, Data Visualizations, Motivation, Purpose, Systems Engineering

In engineering economics education, students learn to make fiscally sound decisions. However, courses often emphasize profit maximization without sufficiently addressing social and environmental responsibilities, such as ensuring community accessibility when choosing a business location (Neal, 2017). For instance, when proposing a new food and beverage venture, entrepreneurs may consult geospatial visualization data (represented in maps) to gain an understanding of quantities such as population density, income levels, and traffic patterns. Engaging with such representations requires learners to interpret distributions, compare data layers, and weigh tradeoffs across multiple quantitative indicators—core practices in statistics and data science. While these metrics can guide profit-driven decisions, they can also inform more socially responsible choices. To help students navigate the tensions between profit and accessibility, this study introduces a place-based learning experience using Google Earth Pro—an open-source geospatial data visualization platform—to engage future entrepreneurs with the ethical dimensions of data- and location-based decision-making. The purpose of this project is to investigate how place-based learning with open-source geospatial visualization software (Google Earth Pro) can help systems engineering students consider more socially responsible goals and adopt "other-oriented" self-transcendent motives as well as their value for learning.

Theoretical Framework

To investigate how data visualization tools influence students' motivation and socially responsible decision-making, we integrate four theoretical perspectives: Data Literacy, Place-Based Education, Self-Transcendent Purpose, and Expectancy Value Theory.

Data Literacy

Data literacy can be defined as the statistical competencies, methods, and techniques that facilitate decision-making (Gould, 2017). These include: acquiring, managing, visualizing, interpreting, evaluating, reading, and using data (Börner et al., 2019; Carlson & Johnston, 2014; Prado & Marzal, 2013; Ridsdale et al., 2015); dimensions that are critical to advancements in science and engineering (Qiao et al., 2024). Competencies that are central to data interpretation

and decision-making is *translating* real world problems into data problems and using results to *advocate* and argue for social benefits (Thacker & Herrick, 2025; Börner et al., 2019; Weiland, 2017; Rubel et al., 2021). In this study, we aimed to offer students opportunities to translate pressing social issues into place-based geospatial data and develop and apply their data literacy skills to select a location of a hypothetical restaurant.

Place-Based Education

A useful framework for contextualizing map data and creating personally relevant data experiences for students is to connect to their "sense of place" (Semken et al., 2017; Semken & Freeman, 2008; Sobel, 2004). A sense of place refers to the emotional, cultural, ecological, historical connections that students develop associated with a geographical location. Map data can tap into one's sense of place because maps can represent one's lived environment, both cartographically and culturally (Duxbury et al., 2018). Further, connecting content to learners' sense of place has the potential to expand learners' attention beyond their own self-interest, and connect to something larger than oneself.

Self-Transcendent Purpose

Self-transcendent purpose refers to the motivation to pursue goals that contribute to the well-being of others or society at large, beyond one's own self-interest (Yeager et al., 2014). In educational contexts, interventions that emphasize self-transcendent goals have been shown to enhance persistence, engagement, and deeper learning—particularly in STEM domains where students may not immediately see the societal relevance of the material (Yeager et al., 2014). Self-transcendent purpose is particularly relevant for future entrepreneurs and systems engineers, where students in these domains are often encouraged to prioritize personal gain or market efficiency.

Expectancy Value Theory

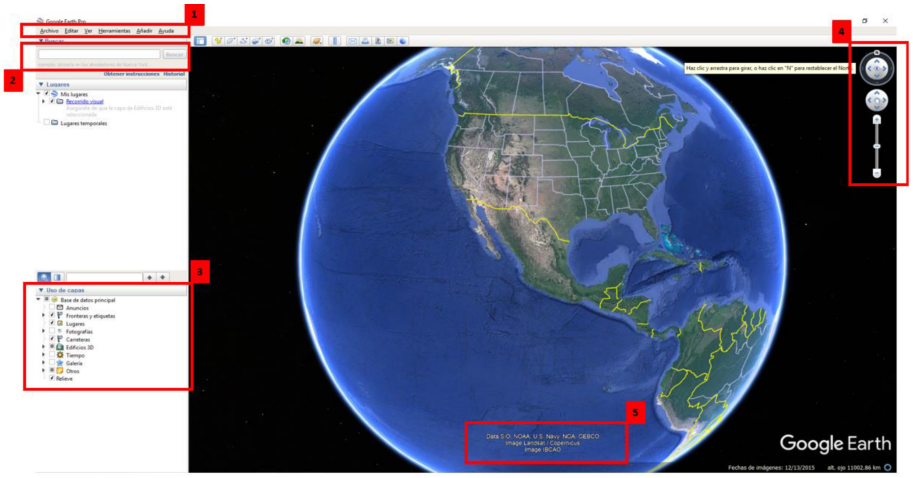
We also draw from *Expectancy Value Theory* (EVT), which proposes that student motivation is driven by learners' expectancy for success and task value (Eccles et al., 1983; Wigfield et al., 2017). According to EVT, there are four different types of task value: *intrinsic value* is when a learner values a task because they find the activity enjoyable for its own sake, *attainment value* is perceived personal importance of a task as it relates to one's identity, *utility value* refers to perceptions that a task may be useful to a learner to achieve their present or future goals, and *cost* is the extent of time and effort that is perceived to complete a task. Evidence suggests that higher value and lower cost perceptions are associated with student persistence, engagement, and achievement STEM (Thacker, 2024, Flake et al., 2015; Wigfield et al., 2017). In this study, we investigate students' the effect of implementing place-based learning visualizations to explore equity issues on students' expectancies for success, value of learning, and cost perceptions.

Gaps in the Literature

Though there are several studies of place-based approaches to science education at the undergraduate level, particularly in biology, geoscience, chemistry, and physics (Thacker et al., 2025, Deringer, 2017; Gosselin et al., 2016; Semken & Freeman, 2008), to our knowledge there are no studies that investigate its effectiveness in systems engineering classrooms nor for promoting self-transcendent motives. Further, the implementation of place-based approaches in diverse cultural contexts remains understudied (Semken et al., 2017). In this project, we address these research gaps by addressing the following research questions: *(1) To what extent does using geospatial data visualizations in a systems-engineering course influence undergraduate students' perceptions of: self-transcendent purpose, expectancy, value, and cost compared to a comparison group? (2) To what extent are these outcomes retained after 5 months?*

Methods

Data & Analysis



To address our research question, we conducted a quasi-experimental study at Tecnológico de Monterrey, a large university in Northwestern Mexico. A total of $N = 63$ undergraduate students in Industrial and Systems Engineering were recruited from three sections of a five-week course, *Economic Evaluation of Projects* (see Table 1 for participant characteristics and descriptive statistics for all analytic variables). A sensitivity analysis using G*Power revealed that this sample size is capable of detecting an effect size of $f^2 = 0.13$ using an F test with two predictors, power of .80, and alpha level of .05 (Faul et al., 2009). The course culminated in a final project where students applied engineering economic principles to propose a new food and beverage venture. This study was embedded within a one-week module focused on market feasibility analysis, where students selected a strategic location for their proposed restaurant. During this week, one of the three courses continued with instruction as usual and selected a restaurant location without using map software (control group; $n = 22$), while the other two courses made use of geospatial visualization tools in selecting a restaurant location (treatment groups; $n = 39$). The study received approval by the *Comité Institucional de Ética en la Investigación*, Tecnológico de Monterrey (P-EIC-202505-001).

Table 1: Descriptive Statistics by Condition

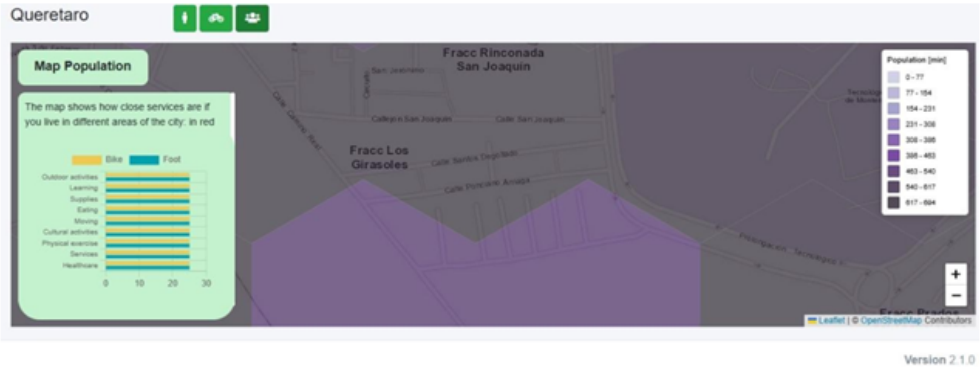
Figure 1 provides a summary of the activities in the treatment condition with screenshots of the visualizations. Students in the treatment groups received a tutorial on using Google Earth Pro to conduct their analysis. They learned to import and overlay shapefile data onto the map, specifically focusing on the Social Backwardness Index (*Grado de Rezago Social*, GRS) at the census-tract level. This enabled them to visualize socioeconomic disparities across the city. They were prompted with guiding questions to analyze this data, challenging them to identify a location that not only promised profitability but also served a community need. To supplement their analysis, students also used the 15-Minute City Web App (Bruno et al., 2024) to explore additional data layers, such as population density and walkability. The assessment was the justification for their final restaurant location, which was a key deliverable in their final project.

Figure 1: Examples of the Place-Based Learning Activity Guiding Students Through Socially Responsible Restaurant Site Selection, In Chronological Order

(A) An In-Class Tutorial for Google Earth Pro



(B) Social Backwardness Index (GRS), Where Darker Colors Indicate Greater Social Disadvantage

Strategic location: Querétaro, Tec de Monterrey Zone

After some research and using some tools like google earth and the 15 minutes city web app, we were able to ascertain that the area of Prolongación Tecnologico and Plaza San Pablo has the following benefits:

- High foot traffic of students and office workers.
- Existing successful taquerias (providing customer demands)
- A constant mix of daytime and nighttime consumers.
- Good population and economic growth.

(Screenshot from the 15 minutes city web app of the maps and its population near Tec de Monterrey)

(Screenshot from the google earth app of the economic level found in the area near Tec de Monterrey)

(C) Example of a Map Produced by a Student Team for Their Restaurant Location Proposal

In contrast, students in the control group did not receive training in geospatial tools or access to the 15-Minute City Web App. Instead, they spent the time brainstorming possible restaurant locations based on general knowledge and intuition. During these sessions, the instructor provided comments to steer their thinking toward customer demand and market potential, but without the structured data-driven approach available to the treatment group.

Materials

Prior to engaging in the restaurant project, students completed a survey of their self-transcendent motives (Yeager et al., 2014), expectancy, value, and cost (Kosovich et al., 2015), and a demographics questionnaire. Immediately after the project, as well as five months later, students completed all items other than the expectancy measure. The *Self-Transcendent Motives Scale* was adapted from Yeager et al., (2014) and consisted of six items across two subscales: Self-transcendant motives (motivation derived from improving the well-being of others; three items) and self-oriented motives (that prioritize personal needs and interests; three items). The *Expectancy Value Cost Scale* was adapted from Kosovich et al., (2015) and included ten items across three subscales (expectancy for success, task value, and cost perceptions). Both scales required participants to respond to statements using a five-point scale ranging from 1 = *not at all true* to 5 = *completely true.* Further, we included five items from the *Systems Usability Scale* (Lewis et al.; 2018) to assess the extent that students' liked using the technology. Internal reliability for all scales at pretest and posttest were judged using Cronbach's alpha, and are reported in Table 1; all items are reported in the Supplemental Materials, Appendices A–C.

Prior to analyses, we assessed if student characteristics differed by condition. Chi-Squared and t-test analyses showed that student gender, comfort speaking English, and STEM major status were independent of condition (all $p > .564$). However, students' year of study was significantly higher in the control group ($p < .039$; namely there were fourth-year students in the control group than in the treatment). Thus, we included "year of study" as a covariate in all analyses. See Table 1 for descriptive statistics for all analytic variables by condition.

Analytic Strategy

We used two-level multilevel models with time nested within individuals to examine treatment effects on each outcome. Models included fixed effects of time, condition, and their interaction, with random intercepts for participants, and year of study as a covariate. Model assumptions were evaluated by inspecting residual distributions and residual-versus-fitted plots to assess normality and homoscedasticity, and no substantial violations were observed. Multilevel modeling was used to accommodate the dependence of repeated measures and to retain cases with incomplete data under a missing-at-random assumption. The reduced-form model can be described by:

$$\begin{aligned} Y_{ti} = {} & \gamma_{00} + \gamma_{10}(Posttest_{ti}) + \gamma_{20}(Followup_{ti}) + \gamma_{01}(Treatment_i) + \\ & \gamma_{11}(Posttest_{ti} \times Treatment_i) + \gamma_{21}(Followup_{ti} \times Treatment_i) + \\ & \gamma_{02}(Year) + r_{0i} + e_{ti}, \end{aligned}$$

where subscripts t and i denote time points nested within individuals. The coefficients γ_{10} and γ_{20} represent the main effects of time, γ_{01} the baseline group difference, and γ_{11} and γ_{21} the primary interaction effects of interest. r_{0i} accounts for participant-specific random intercepts, while e_{ti} represents the residual error.

Expectancies and usability outcomes were only measured at posttest, and were thus analyzed using linear regression models. In these models, the treatment condition was the main predictor, and covariates were year of study, and for expectancies, pretest scores.

Results

Intervention effects across three time points are presented in Table 2. Compared to pretest scores, we found significant main effects of time in self transcendent purpose, self-oriented purpose, and cost at posttest and follow-up. Self-oriented purpose was higher in the treatment

group compared to the control at pretest, but at posttest and follow-up, significantly lower—suggesting that the intervention inhibited self-oriented purpose over time. We also found lower cost perceptions in the treatment group at posttest, though this effect was not retained at the follow-up measurement. There was no significant effect of time or condition on value.

Students also reported significantly lower levels of technology usability in the treatment compared to the control condition (b = –0.448, SE = 0.192, p = 0.024). We found no significant treatment effects on expectancy.

Significance

Findings from this research contribute to both theory and practice in data-oriented STEM and entrepreneurship education, and place-based pedagogy. Theoretically, our study provides novel empirical support for the idea that place-based, geospatial data visualization activities centered on social issues can shape self-oriented motives and cost perceptions, two motivational constructs that have been shown to predict persistence, meaningful engagement, and achievement in STEM fields (Flake et al., 2015; Yeager et al., 2014). Prior research on place-based education and self-transcendent motives has largely focused on U.S.-based student populations and science disciplines (e.g., biology, chemistry, physics; Deringer, 2017; Gosselin et al., 2016; Semken et al., 2017); our findings expand this work by demonstrating similar benefits in systems engineering education and within a Latin American cultural context.

Practically, this study provides a model and lesson structure for integrating free and open-source data-visualization software (Google Earth Pro) into systems engineering coursework to support socially responsible entrepreneurship and equity-mindedness. Rather than positioning business decision-making as solely profit-driven, this approach encourages students to consider trade-offs between economic gain and social impact, such as the placement of businesses in areas

with fewer resources or higher need. Our results suggest that this kind of spatial, ethically informed, data-focused decision-making task may reduce students' self-focused motives and perceived task costs—two barriers to sustained engagement in STEM and entrepreneurship coursework (Flake et al., 2015; Yeager et al., 2014).

Finally, by highlighting the usability challenges students experienced with the technology, our study underscores the need for scaffolded instruction when introducing geospatial tools in undergraduate settings. As interest in place-based and data-informed education grows, especially in applied disciplines like engineering and social sciences, educators must strike a balance between cognitive demand and accessibility to ensure that such tools enhance rather than inhibit learning and motivation.

INVESTIGATING HIGH SCHOOL STUDENTS' EMERGENT PROBABILISTIC REASONING USING A DIE SIMULATION ACTIVITY

Nina G. Bailey
Montclair State University
baileyn@montclair.edu

Traditional probability instruction often emphasizes rote, formulaic procedures over conceptual reasoning, leaving students with persistent misconceptions such as equiprobability bias and confusion between empirical and theoretical probability. This multiple case study examined high school students' probabilistic thinking during a simulation-based dice activity. We used a priori theoretical coding to assess how students' reasoning evolved across the activity. Our analytical framework distinguished between local and global resources, with each category further characterized as either compatible or incompatible. Findings revealed that all students demonstrated some understanding of the law of large numbers by the end of the activity, though some misconceptions persisted. Results suggest that probabilistic reasoning is nonlinear since students shifted between compatible and incompatible thinking throughout.

Keywords: Probability, High School Education, Simulation-Based Learning

In our data-driven world, understanding probability is essential for equipping students with the tools to make informed decisions, interpret information critically, and recognize patterns. Despite its importance, probability is often taught in isolation, reduced to rote calculations and formulae memorization. When instruction focuses primarily on symbolic manipulation and procedural tasks, research suggests students struggle to reason probabilistically beyond textbook scenarios (Fischbein & Schnarch, 1997; Konold et al., 2011). As a result, they are left with an incomplete understanding of probability and find it difficult to connect intuitive ideas with formal representations, limiting their grasp of foundational concepts such as randomness, variability, and uncertainty.

Attending to students' misconceptions about probability is crucial for designing instructional materials that address and mitigate these misunderstandings. In this study, we drew from work of Groth et al. (2021) and Pratt (2000) to develop a framework for assessing students' thinking about probability as they engaged in a simulation-based probability activity. The framework captures how students' reasoning evolves, from short term probability events, to understanding of the law of large numbers. We aimed to understand how students build connections between empirical evidence and theoretical probability.

Background Literature

Decades of research highlight persistent challenges in how students reason about probability. Despite formal instruction, students rely on flawed, intuitive ideas, leading to errors in reasoning (Fischbein & Schnarch, 1997; Groth et al., 2021; Konold et al., 2011). One common misconception is equiprobability bias, which is the tendency to assume all outcomes in a probability situation are equally likely, even when evidence suggests otherwise. This bias becomes more pronounced with age (Fischbein & Schnarch, 1997), suggesting that without targeted instruction, incorrect probabilistic reasoning becomes more deeply entrenched over time. Some students struggle to differentiate between empirical and theoretical probability. They often generalize based on very small datasets, not noticing that experimental results get closer to theoretical ones as the number of trials increases (Konold et al., 2011). Simulations, while

promising as instructional tools to represent theoretical probabilities, present their own challenges. Some students view simulations as perfect representations of theoretical probability, discounting the role of chance and randomness. They may struggle to articulate what the simulation represents or how it relates to theoretical models (Lee et al., 2016). Without opportunities to explore simulations, interpret distributions, and practice application in real-world scenarios, research suggests that students: (a) fail to develop an intuitive understanding of randomness and variability, (b) over trust small samples, (c) struggle to reconcile empirical probability with theoretical models, (d) remain stuck at procedural fluency, and (e) do not internalize the Law of Large Numbers (Fischbein & Schnarch; 1997; Konold et al., 2011).

Framework

The aim of this study is to understand and characterize students' probabilistic thinking through simulation-based learning (SBL). SBL is a pedagogical approach that replicates key features of real-world scenarios, enabling learners to engage in authentic practices while bypassing real-world constraints such as time, safety risk, cost, or replicability (Chernikova et al., 2020). The SBL activity used in this study recreates the context of rolling a die multiple times to facilitate the exploration of probability concepts and is grounded in constructivist views of learning, in which students build upon and strengthen their existing knowledge of probability through active engagement with meaningful tasks (Piaget, 1964).

Pratt (2000) argued that learners often hold multiple, and sometimes contradictory, intuitions simultaneously when making sense of probability concepts. For instance, a student may understand that each number on a fair six-sided die is equally probable (1/6 chance), but simultaneously expect even numbers to be more probable. Drawing on situated cognition (Lave, 1988; Nunes et al., 1993), Pratt (2000) suggested that these conflicting, yet coexisting intuitions can be understood as products of participation in different learning environments, where the development of knowledge is constructed by the tools, people, and affordances specific to that environment. Groth et al. (2021), suggested that early probabilistic thinking unfolds in cycles where children move back and forth between different conceptions and forms of reasoning as contexts change. Thus, students' intuitions may change when the problems they encounter feature slight variations in wording, question structure, and the type of reasoning required. These subtle contextual changes can trigger inconsistent, or even contradictory, ideas as students figure out how to apply new concepts across tasks.

Additionally, students' thinking develops over time in ways that can be described by developmental theories. Piaget's theory of development (1964) conceptualizes learning as a gradual progression through different stages as a child ages, with each stage characterized by distinct forms of reasoning. From this perspective, formal probabilistic thinking emerges gradually. A Neo-Piagetian elaboration of this perspective is described by Biggs and Collis' (1991) Structure of the Observed Learning Outcome (SOLO) taxonomy, which models five cognitive modes: sensorimotor, ikonic, concrete-symbolic, formal, and post-formal. Groth et al. (2021) drew on the SOLO taxonomy to frame early probabilistic thinking within the ikonic mode. Within this mode, children often rely on mental images, stories, their imagination, and prior experiences to make sense of probability concepts. Groth et al. (2021) argued for an important distinction between two types of ikonic reasoning in probability, that is, normative-compatible and normative-incompatible; the former describes children's informal, early conceptions that are productive when further developed, and the latter describes conceptions that are unproductive and unaligned with probabilistic principles. In the next section, we describe

how we adapted these frameworks and stages of thinking to develop a novel codebook that characterizes students' thinking as they progressed through our SBL activity.

To frame our work, we drew from Pratt's (2000) local and global resources and Groth et al.'s (2021) types of reasoning, and Fishbein and Schnarch's (1997) research on misconceptions. Pratt (2000) introduced local and global resources. Local resources (i.e., unpredictability, irregularity, unsteerability, and fairness) capture intuitions developed from experience with short term probability, while global resources (i.e., probability, large numbers, and distribution) reflect more formal concepts grounded in long-term probability.. *Unpredictability* captures the recognition that the next outcome is unknown. *Irregularity* refers to the absence of an obvious pattern in the sequence of outcomes. *Unsteerability* reflects the understanding that outcomes cannot be controlled. *Fairness* describes a perception that outcomes are balanced or equal, without talking about probability (e.g., when rolling a die six times, assuming each number must appear once, as this is fair). *Probability* refers to students' recognition that the proportion of outcomes for each possibility is predictable. *Large numbers* captures the understanding that while short-term results are unpredictable, frequencies stabilize and converge as the number of trials increases. *Distribution* refers to the idea that outcomes can be controlled by how you represent the possibilities.

Groth and colleague's (2021) study focused on proposing a theoretical framework called the Structure of Early Probabilistic Thinking (SEPT) to guide curricular decisions and characterize young children's learning. The appeal of Groth et al.'s work is the distinction between compatible and incompatible reasoning. Since we are focused on secondary students' probabilistic reasoning, we drew from Fischbein and Schnarch (1997) who described the evolution of misconceptions that arise when students engage with probability tasks from grades 5–11. Their hypothesis was that misconceptions would dissipate as students learned more formally about probability. They found that to be partially true, while some misconceptions grew weaker, others grew stronger. To operationalize compatible and incompatible reasoning for the context of this study, we drew from Fishbein and Schnarch (1997) and decided to categorize incompatible reasoning by the persistent use of misconceptions and personal beliefs (e.g., consistently ignoring sample size when estimating probability, believing one can influence random events). While Fishbein and Schnarch (1997) did not explicitly address compatible reasoning, we operationalized compatible reasoning as the capacity to engage with a probability task without the interference of intuitive-based misconceptions.

Methods

In this exploratory multiple case study (Yin, 2018), we aimed to answer the research questions: (1) How do high school students utilize probabilistic resources and reasoning when engaging in an SBL probability activity? (2) How do their resource use and reasoning change throughout the course of the activity? In the subsequent sections we will describe the cases (e.g., participants), the SBL activity, data collection, and analysis.

Cases

Each of the four cases features a rising high school senior. Three of the four cases were female students: Juliana, Annie, and Hannah. One case was male, Michael (all names are pseudonyms). The participants all attended a large urban high school in the Northeast U.S. at the time of the study. The cases were bound by time and context. All participants were enrolled in a program in which they were dually enrolled in high school and a large university. To be part of this program, the students had to apply and meet G.P.A. requirements. They took an introductory

statistics course at the university with a college professor during the Summer 2025 semester. The SBL activity took place after the students completed a unit on descriptive statistics.

The SBL Activity

The activity began with a prompt that asks students to predict and sketch the outcome of 10 die rolls, and were asked to respond to the prompt: What do you think will happen if you roll a die 10 times? Then, they ran a 10-roll simulation and were asked: What did you observe in your 10 rolls?. In the second phase of the activity, students were asked: If we rolled this die 60 times, what would you expect to see? Then they ran 50 more rolls using the simulation for a total of 60 rolls (see Figure 1 for sample output), and were asked to compare their expectations with the simulated outcomes by responding to the prompt: What actually happened when you rolled the die 60 times? Then they were directed to compare their results from 60 simulated rolls with a neighbor. In the final phase of the activity, students simulated 240 rolls (see Figure 2) observing how the results converge toward the theoretical probability and a more uniform distribution, despite some residual variation. Students were given the following prompt: Now compare your charts with your group. How different are your results from others? Why do you think these differences occurred? Although students completed the activity independently in Amplify, certain prompts required brief comparisons with nearby peers to discuss similarities and differences. Mentions of peers in the findings reflect how each student individually described or interpreted discussion with a peer.

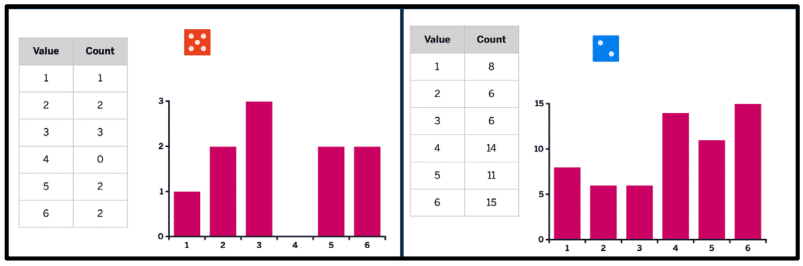

Figure 1: Sample Output after 10 and 60 Simulated Rolls

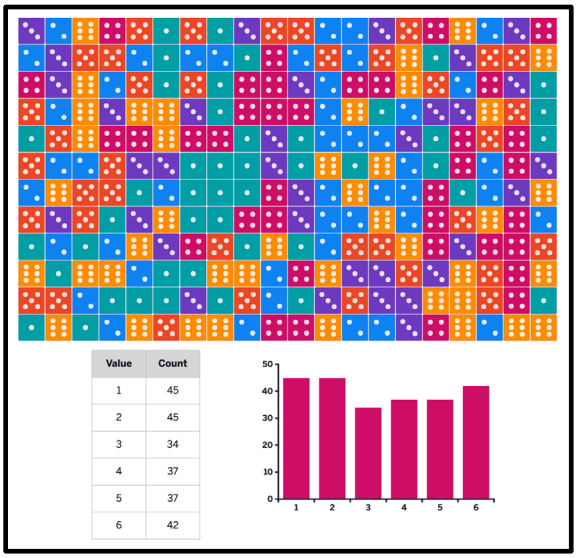

Figure 2: Sample Output after 240 Simulated Rolls

Data Collection

Each student individually completed the *Die Hard* task in Amplify during class (movie and misconception puns intended). Amplify saves student responses and simulation results. The data was extracted from Amplify after final grades posted to adhere with IRB. Data included the students' simulated and written work from the *Die Hard* Amplify task. Screenshots of each page of the activity were blinded for analysis.

Analysis

Blinded screenshots of the students' written responses to each prompt were coded using a priori theoretical coding using an analytic framework based on Pratt's (2000) global and local resources layered with Groth et al.'s (2021) compatible and incompatible reasoning. In total, the analytical framework included codes for six resources (e.g., large numbers), each paired with reasoning classifications (e.g., compatible). For most resources, responses were categorized as either compatible or incompatible, resulting in 14 initial codes. For the *large numbers* global resource, we introduced a third code, *pre*, thus resulting in three possible classifications (pre-compatible, compatible, incompatible) for that resource, and 15 codes overall. Coding proceeded in two stages. First we coded for the presence of local and global resources (e.g., *irregularity*). Second, we coded for compatible or incompatible reasoning (e.g., *irregularity-compatible*). The codebook was refined using the protocol developed by DeCuir-Gunby et al. (2011). After independently coding a random subset of the data, we reviewed all responses we initially coded as *other* to identify any potential new themes. This process led to the addition of a *language* code to capture moments when the students were using words like *chance* or *random* in ways where it was not clear if they meant the colloquial use or the probabilistic use of the word. While Groth et al.'s (2021) compatible and incompatible reasoning was helpful to tease out levels of Pratt's (2000) resource codes, we found that we needed a third level for the global resource, *large numbers.* There were several instances where students did not demonstrate enough evidence to support a compatible code, but did demonstrate some evidence of moving toward such reasoning. These instances led to the development of a *pre-compatible* code that captured instances of partial or emergent reasoning about *large numbers* that did not meet the criteria for *compatible* reasoning, but indicated movement in that direction. For example, a student who noted that as the sample size increases the counts of each outcome begin to level would be coded as *large numbers-compatible*. A student who notices that each outcome is more likely with larger samples, and that each value is not necessarily going to occur in a small sample would be coded *large numbers-pre* to indicate that they are noting ideas that move them toward an understanding of the law of large numbers. After consistency was achieved on a random subset of data, all three authors independently coded all data and discussed discrepancies until consensus was achieved.

Findings

The *Die Hard* Amplify activity was structured around three phases: (1) short term probability; (2) stabilizing, where empirical results begin to approach the theoretical probabilities; and (3) convergence to theoretical probability or the Law of Large Numbers (LLN). We will summarize the findings for each case by activity phase followed by the cross-case analysis.

Case 1: Julianna

In phase one, Julianna demonstrated *unpredictability compatible* and *probability compatible* reasoning when she noted: "You never know what number you get on a die since there is a 1 in 6 chance on getting any number," acknowledging both the equal likelihood of each face and not having a way to know what the next outcome will be. She also predicted "some numbers will be

coming up more than others" and was coded for *unpredictability incompatible*, since short term outcomes can show uneven frequencies. Julianna was later asked to compare her prediction to the 10-roll simulation outcome, she wondered, "why there wasn't only one number that had the most rolls," we coded her response as *irregular incompatible* because she assumed that there was a way to predict an outcome and that it would favor a specific value.

In phase two, her reasoning shifted toward *large numbers compatible* when she predicted that with 60 rolls, "many different number[s] would have the same amount of rolls," and that one or more values "would have the same amount or the most amount of rolls," recognizing that the counts for each outcome/face would get closer to equal as the rolls increased. She also showed *unpredictability compatible* reasoning when comparing the results of her simulation with her peer, "since all of the sides of the die have the same chance it is randomized and there will be a different output for everyone."

In phase three, Julianna showed *irregular incompatible* reasoning when predicting that "three of the same numbers were going to have the same amount of rolls" when rolling the die 240 times, because she tried to predict a pattern and arbitrarily chose three. Finally, when simulating thousands of rolls, she noted, "when I increased the number of rolls the amount of rolls for each side kind of became equal," reflecting *large numbers compatible* reasoning as she recognized that frequencies stabilize with more trials.

Case 2: Annie

In the first phase of the activity, Annie stated that she believed that certain numbers, like 5 or 6, would appear more often, due to the "randomizing formula" which we coded as *irregular incompatible*. She assumed a pattern (i.e., expecting to see 5's or 6's) where no obvious pattern should exist. Annie wondered "[if] there is a way to find out what number will be next for sure" which was indicative of *unpredictability incompatible* reasoning since there is no way to know or predict the next outcome.

In the second phase, Annie assumed higher or lower numbers would show more frequently because "extremes are more common," thus assuming a pattern in a sequence of outcomes where one should not exist. She was also coded for *language* because we could not discern the meaning of "extremes." Later, Annie shifted to *probability compatible* reasoning when she simulated 60 rolls, recognizing that "every number has an equal chance." Her prediction that increasing rolls "would show an even greater difference between the most common rolls and the least common rolls" was coded as *large numbers* and *distribution incompatible* because she assumed that difference would be persistent and noticeable even after we increase the number of rolls significantly.

By the final phase with 240 rolls, Annie noticed that "the graph begins to even out and have no extremes," reflecting *distribution* and *large numbers compatible* reasoning as she recognized that frequencies stabilize with more trials and that the graph is uniformly distributed.

Case 3: Hannah

In phase one, Hannah showed *probability incompatible* reasoning when she assumed numbers 3 and 4 "have a higher probability [of] being rolled" because they appeared more frequently in the simulation. When asked to predict 10 rolls, she demonstrated *unpredictability compatible* reasoning, noting that "I think I will get the same numbers more than once and some won't be rolled at all," demonstrating awareness that the next outcome cannot be known.

In phase two, when comparing her 60-roll simulation with peers, Hannah said, "I think these differences occurred because the probabilities of a number being rolled vary a lot." Her response was coded for *language* as use of "probabilities" and "vary a lot" was unclear. When predicting

the effect of increasing rolls, she showed *large numbers compatible* reasoning, expecting "all numbers showing up more than once as there are more trials and therefore more chances of them being rolled."

In the final phase, after simulating 240 rolls of the die Hannah noted "all of us [are] noticing a more even graph … these differences occurred because the probability of the numbers showing up increases as we add more trials," this was coded as *distribution compatible* since she noticed that graphs are getting more even, and *language* for unclear use of the word "probability." When simulating as many rolls as possible she described the graph as "almost a straight line with only small bumps or peaks" which we coded as *distribution compatible*. Her final reflection that "increasing the number of rolls also increases the probability of the numbers showing up, which makes the graph more even" was coded as *large numbers compatible* since she recognized that frequencies stabilize as the trials increase, and *distribution compatible*.

Case 4: Michael

In phase one, Michael showed *unsteerability incompatible* reasoning when he assumed that number four appeared the most due to "the strength that you roll the die at," because he assumed other unrelated elements (i.e., strength or force) would influence the outcome. When predicting 10 rolls, he wrote, "it'll give me a random assortment of numbers that may or not repeat," and this was coded as *unpredictability compatible*. In comparing his prediction to the simulation, he wrote, "my prediction was completely different from my outcome since the odds of the die are made to be random." We coded his response as *language* since the use of the word "odds" was unclear and we could not determine if he meant the odds of faces or the odds of the theoretical probability.

In phase two, after simulating 60 rolls, Michael wrote, "every outcome is equally possible and no one outcome will be the same," and we gave his response three codes: (a) *probability compatible*–he recognized that each face is equally probably, (b) *language*–it is unclear what "outcome" he is referring to, and (c) unpredictable compatible–he sees there is no way to predict the outcomes of his group members. When predicting 240 rolls; he expected "more variety in the graph." We coded his response as (a) *large numbers compatible* because he describes the count of each face increasing as the number of rolls increases and (b) *language* because we could not discern what kind of "variety" he was anticipating.

In phase three when simulating thousands of rolls, Michael wrote, "increasing the rolls increases the odds that all the numbers will roll an equal amount of times," we coded this as (a) *large numbers compatible* since he acknowledged that the counts for each face stabilize as the number of rolls increases, and (b) *language* since we are not clear what "odds" he is referring to.

Cross-Case Analysis

As the activity progressed, students started showing evidence of the *language code* as they began to grapple with more complex concepts and terminology. It was unclear if the students were confusing colloquial and probabilistic definitions for their word choices (e.g., chance, odd, vary) or just using more informal colloquial language when they felt challenged. Simultaneously, they started to show more nuanced understanding of evening distributions, and convergence to theoretical probability concurrently with some incompatible reasoning. By phase three, each student evidenced *large numbers compatible*, which is indicative of some movement toward understanding of LLN. Every student alternated between various compatible and incompatible probabilistic reasoning, indicating at least for these students probabilistic reasoning develops non-linearly.

Discussion

In the first phase we mostly saw instances of *unpredictable compatible*, indicative of the students' awareness that we can't know what happens in the short term, and *irregular incompatible* thinking, where some students assumed that the patterns that emerge in the short term are a basis for making assumptions about the theoretical probability. Together this is indicative of what previous research pointed to, that probability is challenging, or in Pratt's words "probability is hard" (2000, p. 602).

In the second and third phases, most participants were coded for *language* which potentially indicates that students lean on informal or colloquial language when they are challenged. It is possible that some students were aware of the differing definitions between the colloquial and probabilistic uses of terms, such as odds, vary, and chance. In those instances, it is possible that students move back and forth between colloquial and probabilistic definitions. Just as students move in a non-linear, sometimes contradictory fashion when engaging in probabilistic reasoning (Pratt, 2000), the language they use to communicate such understandings is also likely to be unstable. Future research is needed to understand the role of how students navigate using probabilistic terms that are used in different manners colloquially.

By the end of the activity, every student exhibited some form of large numbers compatible thinking. Students moved from inconsistent or incompatible reasoning, to reasoning that aligned with the idea of the law of large numbers. Regardless of how some students began thinking (compatible or incompatible) they all shifted back and forth throughout the activity in their own ways. All students concluded the activity with varying levels of compatible LLN thinking. This highlights how the students can hold both compatible and incompatible ideas as they work through new concepts. This finding corroborates Pratt's (2000) finding that students navigate probabilistic reasoning by moving between local and global resources such that compatible and incompatible reasoning coexist throughout the learning process rather than following a linear progression. Our findings are also consistent with findings by Fischbein and Schnarch (1997) who demonstrated how some misconceptions remain persistent or even grow stronger as students gain formal probability instruction (e.g., ignoring sample size).

This study adds to a growing body of research affirming that probabilistic thinking develops in a nonlinear way. For K–12 education, this means that probability cannot be confined to the upper-level grade bands only. All K–12 students need the opportunity to refine their probabilistic reasoning, especially as it grows nonlinearly. Prior research has persistently shown that the intuitions students form early shape how they engage with probabilistic thinking for years to come (e.g., Pratt, 2000). We added nuance to existing frameworks for probabilistic reasoning by showing how compatible and incompatible reasoning can coexist. Future research should examine how patterns of probabilistic thinking manifest across more diverse student populations and educational contexts.

Machine learning (ML) remains absent from high school math classrooms, due to its perceived technical complexity and reliance on coding. Google's Teachable Machine makes core ML processes accessible through data-driven, sensor-based approaches without programming. We examined high school students' (n = 51) perceptions of website usability, perceived ML understanding, and performance on a multiple-choice assessment following two interventions: image-based and sound-based model training. Students in both conditions reported similarly positive experiences, with no statistically significant differences in usability or perceived understanding. Although image-based students scored higher on the assessment, the difference was not statistically significant. Item analyses showed stronger data and training performance in the image condition, with similar understanding of behavior and generalization across groups.

Keywords: Machine Learning, High School, Data Science

Machine learning (ML), a subset of data science, involves training computational models on prior data to generate predictions or classifications (Alpaydin, 2020). ML concepts such as feature selection, training and testing data, generalization, and model accuracy are becoming important components of K–12 data science education (Touretzky et al., 2025), yet ML remains absent from secondary math classrooms. This gap persists for several reasons: ML is inherently technical and code-intensive, obscuring students' access to core conceptual ideas (Sanusi et al., 2022); classroom-appropriate tools and visualization supports are limited; and teacher preparation in ML content and pedagogy remains inadequate (Amaniampong & Oyelere, 2024).

Web-based ML tools that require no coding foreground data practices (e.g., collecting, labeling, training, and evaluating) while making model behavior visible. Less is known, however, about how different data representations shape students' understanding of these processes. Image-based training foregrounds visual features (patterns in space), whereas sound-based training highlights temporal patterns and signal variation (patterns over time)—differences that may influence how students conceptualize features, interpret performance, and reason about generalization. In this study, we examine students' experiences with a web-based ML environment (Google, n.d.) implemented through a data-driven instructional approach (Morales-Navarro & Kafai, 2024) across two conditions: image-based and sound-based model training. This study addresses two questions: (RQ1) How do students' perceptions of website usability and ML understanding differ between image- and sound-based interventions? (RQ2) To what extent do students demonstrate understanding of core ML processes (e.g., data preparation, training, classification), and does this differ by condition?

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Literature Review

Hands-on image recognition tasks can support students' understanding of core ML concepts while surfacing important conceptual tensions (Morales-Navarro & Kafai, 2024). Through structured image-classification activities, middle schoolers demonstrated mastery of image representations, feature maps, kernels, and matrix-based computations (Rajarajan & Martin, 2026), and students in Živković et al. (2025) deliberately added samples for underrepresented categories, adjusted lighting, and retrained models to improve performance. Such engagements can also reshape how students conceptualize ML itself: when high schoolers worked with simplified tools foregrounding features, labels, and training–test distinctions, they began framing ML as a human-assisted, data-dependent process rather than an autonomous system (Kaspersen et al., 2022). For example, students using a one-feature image-recognition model saw that a long fish and a tall giraffe could be misclassified as similar, and that adding a second feature improved accuracy (Toivonen et al., 2022).

Students' conceptions of ML also remain varied and sometimes unstable. Surveying 155 students, Mertala et al. (2024) identified three dominant conceptions—ML as "teaching machines" (34.0%), as coding (7.6%), and as machines learning from data (37.1%)—and found that misconceptions about automation, agency, and human decision-making persisted even among partially accurate definitions. Kaspersen et al. (2022) similarly reported that some students distanced themselves from ML as "very complex," while others recognized human responsibility in feature selection and bias, noting that machines only examine what they are directed to. Toivonen et al. (2022) likewise found that students initially attributed classification errors to their own deficiencies (e.g., drawing ability) before recognizing that performance depends on model structure and training data quality.

The recent work has explored sound-based ML environments that foreground temporal data and signal variation, positioning students not merely as users but as designers who curate, label, and iteratively refine training data (Tedre et al., 2021). Speech recognition and sensor-based tools offer "low-floor, high-ceiling" entry points that make core ML processes visible. Hsu and Chen (2022), for example, had undergraduates train spectrogram-based voice-recognition models to control robotic cars in a computational thinking board game, yielding gains in learning effectiveness and engagement. Such findings suggest sound-based contexts may surface different aspects of data reasoning than image-based environments, warranting closer examination of how representational modality shapes students' understanding of ML.

Method

We introduced ML concepts in three high school classrooms across two southern U.S. districts in Fall 2025; approximately 95% of students identified as African American. One classroom implemented the sound-based condition and two the image-based condition. Each 90–120-minute lesson occurred during regular instruction and followed the same learning objectives, instructional sequence, and design challenges using a web-based ML platform (Google, n.d.). Of 59 survey completers, eight responses were excluded for missing data or uniform response patterns (six image-based, two sound-based), yielding final samples of 34 image-based and 17 sound-based students. A post-intervention survey and assessment compared students' perceptions and conceptual understanding of core ML processes across conditions. The survey included 39 six-point Likert-scale items (strongly disagree to strongly agree); we focus here on website usability, perceived ML understanding, and multiple-choice outcomes. Survey constructs showed strong reliability ($\alpha = .80–.95$), and the 19-item multiple-choice assessment demonstrated good internal consistency (KR-20 $\alpha = .83$), with item difficulty ranging from .28 to .80.

Results

RQ1: Website Usability and Perceived ML Understanding

We compared the image-based and sound-based instructional conditions on students' perceptions of website usability and perceived ML understanding using Welch independent-samples t-tests (Table 1). Mean scores were numerically higher in the image-based condition for both website usability and perceived ML understanding. However, these differences were not statistically significant ($p > .05$).

Table 1: Comparison of Image-Based and Sound-Based Conditions

Construct	Image M (SD)	Sound M (SD)	Mean Difference [95% CI]	Effect Size *d* [95% CI]	*t*	*p*
Website Usability	4.63 (0.66)	4.29 (0.72)	0.34 [–0.09, 0.76]	0.49 [–0.10, 1.08]	1.62	.117
Perceived ML Understanding	5.04 (0.84)	4.71 (0.99)	0.33 [–0.24, 0.91]	0.37 [–0.22, 0.95]	1.18	.249

Perceived ML understanding was moderately correlated with website usability ($r = .59$, $p < .001$). These findings indicate no statistically reliable differences in students' perceptions across conditions, though effect sizes suggest a possible advantage for the image-based condition.

RQ2: Understanding of Machine Learning Process

We compared total scores on the 19-item multiple-choice assessment using Welch's t-test (Table 2). Students in the image-based condition scored higher, though the difference did not reach conventional significance, $t(41.4) = 1.80$, $p = .079$, Mean Difference = 2.26 items, 95% CI [–0.27, 4.80]. The small-to-moderate effect size ($d = 0.49$) suggests a possible but inconclusive advantage for the image-based condition.

Table 2. Comparison of Multiple-Choice Assessment Scores by Condition

Image	Sound-Based	Mean Difference	95% CI	*t* (df)	*p*	Effect Size
11.85 (5.04)	9.59 (3.76)	2.26	[–0.27, 4.80]	1.80 (41.4)	.079	0.49

Subscale analyses showed image-based students outperforming sound-based peers overall (62.4% vs. 50.5%), with the largest gaps in Data and Representation and Training and Model Improvement—particularly data variation, training/test splits, and iterative improvement. Differences were smaller in Model Behavior and Evaluation and minimal in Generalization and Conceptual Understanding, where both groups scored lower. Notably, sound-based students slightly outperformed image-based peers in pattern-based classification and responding to poor results, suggesting domain-specific strengths.

Table 3: Subscale Performance on the Multiple-Choice Assessment by Condition

Scale	Image-Based *M* (SD)	Sound-Based *M* (SD)	Mean Difference	95% CI	Effect Size (d)	*t*	df	*p*	Holm-Adjusted *p*
Overall (19 items)	11.85 (5.04)	9.59 (3.76)	2.26	[–0.27, 4.80]	0.49	1.80	41.4	.079	—
Data	0.58 (0.27)	0.40 (0.17)	0.18	[0.05, 0.30]	0.74	2.83	45.8	.0068	.027

Scale	Image-Based *M* (SD)	Sound-Based *M* (SD)	Mean Difference	95% CI	Effect Size (d)	*t*	df	*p*	Holm-Adjusted *p*
Training	0.75 (0.31)	0.53 (0.35)	0.22	[0.01, 0.42]	0.66	2.13	29.2	.042	.126
Model Behavior	0.70 (0.29)	0.61 (0.26)	0.09	[–0.07, 0.26]	0.34	1.17	34.8	.252	.504
Generalization	0.47 (0.32)	0.43 (0.23)	0.03	[–0.13, 0.19]	0.11	0.42	43.0	.675	.675

Discussions

This study examined how image-based versus sound-based model training shapes students' perceptions and demonstrates understanding of core machine learning processes. Although overall differences between conditions were not statistically significant, the pattern shows that representational modality may influence which aspects of ML reasoning become salient during instruction.

Perceptions of Website Usability and Perceived Understanding of Machine Learning

We found no statistically reliable differences emerged between image- and sound-based conditions in reported website usability or perceived ML understanding. However, mean scores were consistently higher in the image-based condition, with small to approaching moderate effect sizes. We also found that perceived ML understanding was moderately correlated with website usability, suggesting that students who felt they understood the underlying ML processes found the interface more accessible. This relationship reinforces prior work indicating that interpretability and transparency of tools play a central role in shaping students' engagement with ML systems (Kaspersen et al., 2022; Morales-Navarro & Kafai, 2024). These findings suggest that perceptions of usability may be intertwined with conceptual understanding.

Core Understanding of Machine Learning Processes

Students in the image-based condition outperformed those in the sound-based condition on the overall assessment, though this difference was not statistically significant. The moderate effect size and positive mean difference suggest a possible advantage for image-based training.

Subscale analyses revealed a more nuanced pattern. Differences were most pronounced in the Data and Training domains, where image-based students demonstrated a stronger understanding of data variation, training/test splits, and iterative model improvement. After adjustment for multiple comparisons, only the Data subscale remained statistically reliable. In contrast, differences in Model Behavior and Generalization were small, and both groups demonstrated comparatively lower performance in Generalization and Conceptual Understanding.

This pattern suggests that data modality may shape students' reasoning about data practices more than their understanding of abstract model behavior or generalization principles. Image-based intervention, which foregrounds visible spatial features and class distinctions, may make issues of data diversity, feature salience, and misclassification more immediately observable. In contrast, sound-based environments rely on temporal and spectral variation, which may be less perceptually transparent without additional scaffolding. As a result, differences in feature interpretability could influence how readily students reason about the quality of training data and the refinement of models.

These results suggest that the representational format may influence which aspects of the ML pipeline become cognitively salient. Image-based tasks may support reasoning about data composition and feature differentiation, whereas both modalities appear to leave persistent challenges in reasoning about generalization. This aligns with prior findings that students often struggle to move from procedural engagement with ML tools to deeper conceptual understanding of how models abstract patterns from data (Mertala et al., 2024; Toivonen et al., 2022).

This study has several limitations: the sample was modest and uneven across conditions, limiting statistical power; the subscale analyses were exploratory, warranting caution in interpreting domain-specific differences; and the multiple-choice assessment may not fully capture students' ML reasoning processes. Future research should examine modality effects in larger, balanced samples and use qualitative analyses to explore how students articulate feature selection, generalization, and evaluation across representational contexts.

Prospective secondary teachers (PSTs) should have opportunities to analyze student work and construct "second-order models" of student thinking—that is, the PSTs' conceptions of students' thinking as informed by their observations of student work and verbalizations. We detail a qualitative analysis of group discussions from a teaching experiment in a curriculum course for PSTs, where PSTs constructed second-order models of student thinking in response to two hypothetical students' statements about the sampling distribution. Results indicate that PSTs can build diverse types of second-order models of students' statistical thinking but need support to identify a range of evidence of students' knowledge as embedded within their thinking.

Keywords: Sampling Distributions, Prospective Teachers, Second-Order Modeling

Research in teacher education shows that analyzing student work can help pre-service teachers (PSTs) refine their views of what counts as developing mathematical knowledge (Crockett, 2002), recognize students' assets (Krebs, 2005), and use students' thinking in instruction (Crespo, 2000). Given their future role in supporting students' learning of statistics concepts, this raises questions and extends these research directions to how PSTs develop skills in interpreting and responding to students' *statistical* thinking.

We investigate how statistics PSTs interpret and respond to students' thinking, components of teaching noticing (Jacobs et al., 2010), about sampling distributions, a statistical topic known to be challenging for learners (Sharma, 2005; Noll & Shaughnessy, 2012; Ajao et al., 2023). Sampling distributions are central to developing students' understanding of statistical inference (Bargagliotti et al., 2020). Consequently, programs serving PSTs have been encouraged to incorporate sampling distribution pedagogy into their coursework (Lovett & Lee, 2017; Franklin et al., 2015). Research on PSTs and sampling distributions has shown that they attend to some of their statistical properties, like sample representativeness, and not others, like sampling variability (Begué et al., 2023). We combine insights from PSTs' learning of sampling distributions with their ability to notice and respond to student work containing ideas about sampling distributions. We frame our inquiry with Steffe & Thompson's (2000) formulation of first- and second-order models and ask: *In what ways do PSTs model students' statistical thinking in a task designed to elicit teacher noticing about student thinking?*

Theoretical and Analytical Frameworks

According to Steffe and Thompson (2000), *first-order models* are interconnected bodies of knowledge students construct as they make sense of their mathematical and statistical activity. As teachers do not have direct access to this knowledge, they must observe students' thinking through their work to build *second-order models* that aim to approximate students' first-order models. We view PSTs' processes of reviewing student work, hypothesizing about student thinking, and planning responses to that thinking as enactments of second-order model building.

As an analytical framework, we used Wilson et al. (2011) framing of processes that PSTs use to develop second-order models while watching students work on statistics tasks. In *describing*, PSTs state what students did or said without conjecturing about their thinking. In *comparing*,

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

PSTs identify similarities and differences between students' work or verbalizations and their own work or thinking on the task (Didis et al., 2016). In *inferring*, PSTs generate hypotheses about students' thinking and understanding of the relevant concept. Through *restructuring*, they use these inferences to extend their own subject matter and pedagogical knowledge. Following Didis et al., we also include *questioning* about any aspect of students' work or thinking.

Methods

We conducted a teaching experiment (Brown, 1992) as part of a statistics unit of a PST curriculum course at a large, Western U.S. public university, with the featured lesson focusing on sampling distributions. We introduced the sampling distribution of sample means as the distribution of means from repeated samples of a fixed size drawn from a population, engaging in group and whole-class discussions about its center at the population mean and the reduced variability that results from averaging. They then analyzed a dataset of 777 institutions reporting estimated annual personal expenses per student, denoted *EAP spending values* (James et al., 2021), and examined histograms of the population distribution and an approximate sampling distribution generated by simulating 1,000 sample means from samples of 15 colleges (Figure 1).

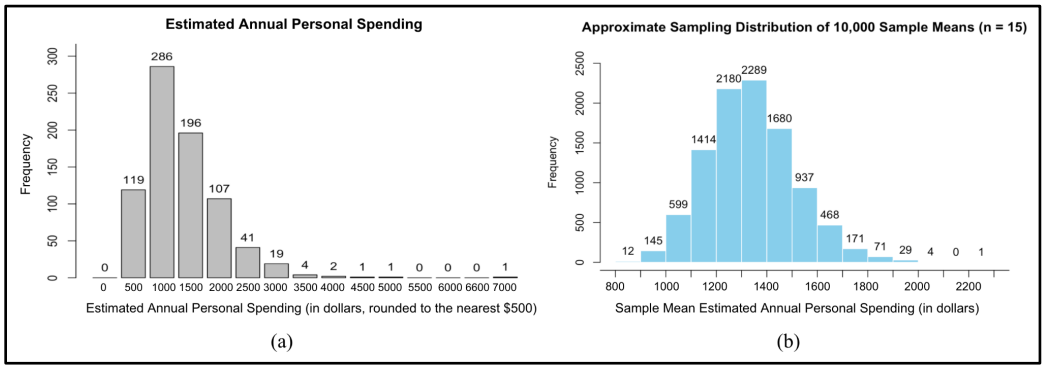

Figure 1: Graphs Given to PSTs

The PSTs were then shown statements from "Lynette" and "Alberto," designed by the first author to reflect common misconceptions about sampling distributions identified by Chance et al. (2004). Alberto's statement read: "*The approximate sampling distribution tells us that (12 + 145 + 599 + 1414)/1000 · 100 ≈ 21.7 percent of colleges in the population have EAPS values greater than $1,200*." Lynette's statement read: "*I don't think these graphs make sense together. I don't understand how there are so many values in between $0 and $1000 in the first histogram, but so few values in between the amounts $0 and $1000 in the second histogram*." We asked PSTs to identify what each student understood or misunderstood and to craft questions they could ask the student to learn more about their thinking. We intended for the PSTs to notice that Alberto calculates a valid percentage from the sampling distribution but references the wrong tail and frames it as a proportion of individual colleges rather than sample means, conflating the population and sampling distributions. For Lynette, we aimed for PSTs to notice that she correctly identifies the difference in proportions within [0, 1000] across the two distributions, yet overlooks that this difference reflects what each distribution measures. PSTs could then build on her observation by acknowledging how averaging reduces the variability of sample means.

Automated transcripts (verified and cleaned by the authors) from four groups of two to four PSTs each served as the primary source of analysis for this study. The data was condensed to

include only on-topic discussion and analyzed at the level of the talk turn. The first and second authors coded two group transcripts (46 of 81 talk turns) using a codebook that defined criteria for the five types of second-order model building described above or *NA* if the PST did not appear to be interpreting the statements. When multiple codes could apply to a single talk turn, we assigned one code according to the hierarchy *describing* < *comparing* < *inferring* < *restructuring*. The first two authors obtained agreement on 85% of the 46 turns. After the first two authors resolved discrepancies through discussion, the first author coded the remaining transcripts. We inductively coded each PST talk turn for its focal statistical idea to identify which aspects of the sampling distribution were emphasized. Examples included "*reading a histogram*" and "*identifying an interval a calculated proportion represents*." Through pattern coding (Miles et al., 2014), we noted connections we observed between the deductive (i.e., the codes describing second-order model-building) and inductive codes (i.e., the codes describing statistical ideas). This allowed us to report the relationship between the content of Alberto's and Lynette's statements, the PSTs' focal statistical ideas, and their second-order model building.

Findings

Figure 2 provides details on PSTs' second-order model-building in talk turns aggregated by groups and statements. For Alberto's statement, PSTs' second-order model-building varied, but most often centered around *describing* and *comparing*. Lynette's statement, in contrast, largely centered on *inferring*. We elaborate more on these patterns with PSTs' responses below.

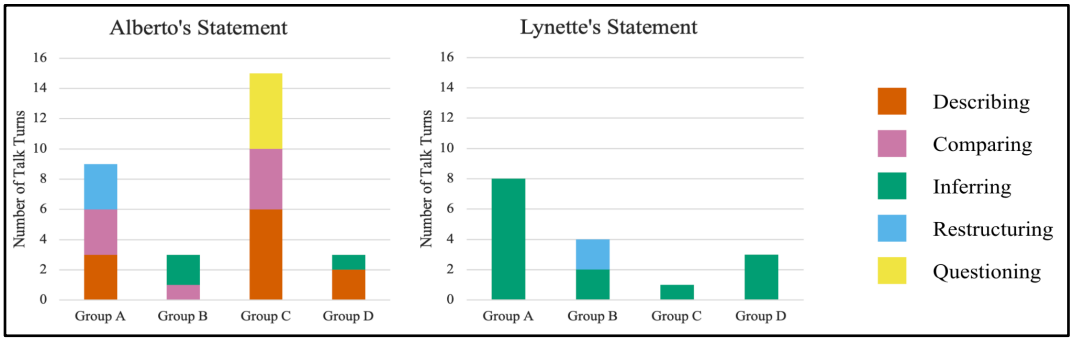

Figure 2: Distribution of Second-Order Model-Building Types Across PSTs' Groups

Responding to Alberto's Statement

The PSTs were attentive to the calculation embedded in Alberto's statement and the tail of the histogram that his proportion, 21.7%, represents (Figure 1(b)). More than half of the talk turns were coded as *describing* and *comparing* in Groups A, C, and D, with many PSTs parsing out and evaluating the steps Alberto completed to obtain 21.7%. For example, Kaylee (Group C) stated, "It's not greater than 1200… It's the ones that fall between 800 and 1200," *comparing* implicitly between Alberto's statement and her own statistical conclusion. Interestingly, none of the PSTs recognized that Alberto did not distinguish that the unit represents a sample mean from a group of colleges rather than a single college's observation.

Some of the talk turns for Alberto's statement did emulate *inferring* and *restructuring*. For instance, Rodney (Group A) engaged in *restructuring* by suggesting the question "Does the right side of 1200 look like 20% of the graph?" and following up with, "There definitely is a nicer way to ask that, but that's what I would ask." Here, Ryder considered how Alberto could benefit from making sense of his calculation and how percentage values might appear on a histogram.

Responding to Lynette's Statement

Unlike their discussion of Alberto's statement, the PSTs explicitly discussed the difference in the type of data the population and sampling distributions illustrate. This knowledge, combined with the ambiguity of Lynette's statement compared to Alberto's, seemed to motivate PSTs toward *inferring* as they constructed second-order models of Lynette's statistical thinking. For instance, Ilyas (Group D) *inferred* from Lynette's thinking and argued that "she understands that this range shows where the center, or majority, of student spending is, but she doesn't get that this isn't what we're measuring. It's a different picture." However, we noticed that while we intentionally designed Lynette's statement to be more ambiguous, we were surprised to see that the PSTs did not engage in *questioning* to inquire about and address these ambiguities.

Additionally, we observed that PSTs primarily focused on how Lynette did not distinguish between the population and sampling distributions, without elaborating on what this difference implies about Lynette's observations—namely, that the averaging process is precisely what produces the reduced variability in the sampling distribution she is observing. Although this point was explicitly discussed prior to the activity, students did not take up this point during their analysis of Lynette's thinking. We hypothesize that PSTs may have still been developing their understanding of sampling distributions while also choosing to examine one facet of Lynette's thinking in depth, rather than extending their analysis to other aspects of her reasoning.

Discussion

Exposure to multiple statements appeared to be productive for facilitating different kinds of model-building activity. Alberto's statement appeared to orient students toward all of Wilson et al.'s (2011) second-order model-building types, whereas Lynette's statement was dominantly followed by PSTs *inferring* about her thinking. However, the PSTs' discussions of Lynette's work highlighted how PSTs may not immediately *question* aspects of work they may need to inquire about. Additionally, we found that the PSTs often did not *restructure* their statistical knowledge for teaching, despite the activity inviting the PSTs to pose questions in response to the statements. These results suggest that PSTs may need further support to inquire about and reflect on the breadth of evidence of student thinking they have access to, so that they may in turn learn how to apply responsive pedagogies characteristic of *restructuring* more consistently.

Moreover, analyzing student statements with distinct conceptions of sampling distributions appeared to cue different statistical ideas in PSTs' discussions. However, we noticed that although PSTs sometimes correctly identify students' struggles with interpreting sampling distributions, they often focused on only one component of those misconceptions. For example, most groups *described* or *compared* Alberto's computational mistake but overlooked his incorrect meaning of a sampling distribution. These observations highlight how PSTs may need support to consider multiple ways that students can (mis)interpret statistical information, visualizations, etc., as statistics is a discipline that relies heavily on interpretation.

These findings should be interpreted considering the study context. First, PSTs in this course regularly practiced interpreting and responding to student thinking (Jacobs et al., 2010), which likely impacted PSTs' discussions. The lesson focused on sampling distributions, a topic PSTs were likely less familiar with, given their limited statistics coursework. Because subject matter knowledge shapes teachers' analyses of student work (Heritage, 2022), results may have differed with more familiar topics, such as algebraic reasoning. This raises an interesting concern, as the PSTs, even with multiple opportunities to build second- order models of the course, experienced challenges in accounting for the multi-dimensional nature of students' statistical thinking.

Consequently, teacher educators may need to draw more attention to the distinctions between teaching mathematics and statistics (Groth, 2007).

In this study, we investigated how undergraduate students' attitudes and perceptions towards mathematics changed over a semester in a data science-focused Quantitative Literacy course. We combined quantitative and qualitative approaches to understand changes in students' attitudes from the beginning to the end of the course. Data sources for the study consisted of undergraduate students' ($n = 39$) responses to the Mathematics Attitudes and Perceptions Survey (MAPS), administered at the start and end of the semester, and pre-/post-interviews with selected students ($n = 14$) to explain the observed patterns. We conducted statistical analyses to examine changes in attitudes, together with a case study analysis to examine how changes in attitudes occurred. The results indicated a statistically significant increase in students' overall attitudes and perceptions toward mathematics.

Keywords: Mathematics Attitudes, Student Perceptions, Quantitative Literacy, Data Science Education

Introduction

Quantitative literacy (QL) refers to developing habits, dispositions, and skills needed to interpret quantitative data in ways that support one's daily responsibilities (e.g., Gillman, 2006; Steen, 2004). Clearly, QL serves an important purpose in today's society, where interpreting quantitative data affects one's voting choices, personal finance, and health management, among other daily decisions. Because of its importance, the broader community has long recognized the significance of QL for postsecondary education. About 30 years ago, organizations such as the Mathematical Association of America (MAA) and the National Numeracy Network (NNN) created focused efforts to promote quantitative literacy in college students (e.g., Sons, 2006). These efforts eventually led to the creation of quantitative literacy requirements at most colleges and universities, where all students were required to fulfill a certain number of quantitative credits to complete their degree.

Since the united effort to require QL courses for college completion was initiated nearly three decades ago, colleges and universities have used various QL curricula. One of the more mainstream approaches was to require traditional mathematics courses, such as college algebra and introductory statistics, to fulfill the QL requirement. Yet these approaches have been met with criticism; for instance, Agustin et al. (2012) provided empirical evidence suggesting that traditional mathematics courses alone do not foster meaningful gains in quantitative reasoning because students failed to demonstrate adequate quantitative reasoning skills. Consistent with this concern, Tunstall (2018) argued that college algebra, even in modified formats, is not inherently designed to develop quantitative literacy. These courses tend to heavily emphasize analytical techniques that are at odds with the very purpose of QL in this modernized era—to

support learners to develop quantitative skills, including computational skills, needed for practical decision making. Further, courses like college algebra and introductory statistics often require intense remediation for learners who do not have the abstract prerequisite knowledge for success. Such remediation has been shown to increase costs for many students and delay graduation (Jiminez et al., 2016; Logue et al., 2019).

More recently, some postsecondary institutions have modernized the QL curriculum to focus on real-world phenomena. These courses have included data science, mathematical modeling, problem-solving, and other curricula that centralize application (e.g., Anderson, 2006; Hartman et al., 2025; Small, 2006; Tunstall et al., 2016). While such courses are clearly consistent with the overall aim to support students in developing quantitative skills for the real world, the modern QL curriculum has been critiqued for its potential to become a remedial enterprise (Steen, 2004). In other words, there is concern that modernized QL courses could become non-rigorous and unsuitable for collegiate education.

Furthermore, notwithstanding the importance of QL to postsecondary education, there has been relatively little empirical research examining students' QL course experiences. Student experiences are vital for understanding the curricula that support learners' skills, attitudes, and dispositions toward quantitative information. Despite growing efforts to modernize quantitative literacy curricula, empirical research has not adequately examined the attitudinal consequences of data science–focused QL courses. Existing studies either emphasize traditional mathematics pathways or rely primarily on quantitative measures without investigating the underlying processes of attitudinal change. Students' attitudes towards quantitative literacy, particularly mathematical attitudes, play an important role in both their mathematics performance and their persistence in STEM (Cohen & Kelly, 2020). Therefore, studying how a modernized QL course shapes students' mathematics related attitudes can offer important insights into its impact on the STEM pipeline—a concern raised by the community.

In light of this, in this study, we share results from students' experiences in *one* data science QL course that focused on developing data skills relevant to students' personal, civic, and professional lives while simultaneously having no pre-requisite requirements. We specifically focus on learners' attitudinal shifts toward mathematics within the course because attitudes are a dispositional dimension of QL (Steen, 2001) and hence a critical component of QL development. Our purpose is not to argue for the supremacy of modern approaches to QL—rather, we aim to show that modern approaches to QL *can* support students' QL development. The following research question guides the overall goal of the research: *How do undergraduates' attitudes and perceptions about mathematics change over one semester in a data science-focused QL course?*

Background

Data Science as a Mathematical Practice

Data science is an interdisciplinary field that connects mathematics, statistics, computer science, and realistic contexts (Conway, 2010; Hazzan & Mike, 2023). Engaging with data science implies conducting analysis on data that emerged as a consequence of a real-world occurrence, to describe, interpret, and predict the behavior of that phenomenon. In doing so, data scientists typically formulate investigative questions about the real-world domain, collect, consider, and retrieve data, perform computational analysis on the data, and make inferences connecting the results to the real-world domain (Bargagliotti et al., 2020; Baumer, 2015). These investigative processes reflect the mathematical and statistical practice standards emphasized in policy documents and by professional organizations (e.g., Bargagliotti et al., 2020; Common

Core State Standards Initiative, 2010), positioning data science as a modern mathematical practice.

Mathematics Attitudes and Perceptions

A growing body of research identifies students' attitudes toward mathematics as an important determinant of academic performance and broader educational outcomes (e.g., Gonzales et al., 2008; Gjicali & Lipnevich, 2021; Mazana et al., 2019; Wakhata et al., 2024). In general, attitudes (understood broadly) have a reciprocal relationship with students' achievement—attitudes support achievement and achievement supports attitudes (e.g., Bayaga & Wadesango, 2014; Ma, 1997). Given the significant role of mathematics attitudes in learning and achievement, researchers have extensively examined the factors that influence their development. For example, students' attitudes toward mathematics have been linked to factors such as perceived value of mathematics (Peixoto et al., 2016), confidence (Barkatsas et al., 2009), self-concept (Stankov et al., 2012), enjoyment (Ahmed et al., 2013), and anxiety (Ashcraft & Faust, 1994), all of which shape how students engage with and respond to mathematical learning experiences. Consequently, across the literature, many researchers have defined attitudes towards mathematics in different dimensions, incorporating affective, cognitive, and behavioral components (Di Martino & Zan, 2011; Haladanya et al., 1983; Hemmings et al., 2010; Koyuncu & Dönmez, 2018; Moyer et al., 2018; Stampoltzis & Giannoulas, 2021; Wen & Dubé, 2022).

In this study, we adopt a multi-dimensional view of mathematical attitudes and beliefs as proposed by Code et al. (2016). In Code et al.'s (2016) framework, mathematical attitudes and perceptions consist of *Confidence* (perceived ability to successfully engage in mathematical task), *Persistence* (Keep going when its challenging), *Growth Mindset* (belief about whether mathematical ability is innate or can be developed), *Interest* (active willingness to engage in mathematical situation), *Real World* (transference of domain-specific knowledge to novel situations), *Sense Making* (students' perspectives on the nature of their personal mathematical knowledge), and *Answers*, hereafter Nature of Mathematics, (views on the ontological nature of mathematics and nature of solutions to mathematics problems), each of which reflects the extent to which students hold *expert-like views* about learning and doing mathematics. For this study, to measure students' mathematical attitudes, we adopted Code et al.'s (2016) Mathematics Attitudes and Perceptions Survey (MAPS) because the instrument was designed and validated with undergraduate students who resembled our target population, and the MAPS framework explicitly treats attitudes as a multidimensional attribute, aligning with our theoretical stance.

Methods

We employed a multiple-method research design (Creswell, 2003) to examine the changes in students' attitudes and perceptions towards mathematics over the course of one semester.

Study Setting and Participants

Our study's context is situated within a data science-focused QL course (STAT 1080) at a midsize research university in the Western United States. The STAT 1080 course was inspired by the success of the University of California Berkeley Data Science curriculum (Adhikari et al., 2022) and teaches select topics from Irizary (2019). The course provided students with a contemporary introduction to foundational statistical ideas through computational practice rather than manual calculation. The curriculum emphasized relevance, real-world inquiry, and the use of R programming to analyze, visualize, and interpret data. Major concepts included data exploration and visualization, correlation vs causation, randomness and simulation, and hypothesis testing and prediction. A total of 77 students were enrolled and completed the course, which met twice per week. The fourth author served as the instructor. A typical class session

began with an introduction to a real-world example (e.g., election polls), after which students learned how to use R programming to explore similar types of data and worked collaboratively to explore data and interpret their results.

The participants were students enrolled in STAT 1080 during Fall 2025. A total of 63 students completed the pre-survey at the beginning of the semester, and 39 completed the pre- and post-survey, resulting in a retention rate of 62%. For the qualitative data collection, 14 students participated in interviews from the pool of 39 students at the beginning and end of the semester.

Data Collection and Analysis

Quantitative data were collected using MAPS, developed and validated by Code et al. (2016). In MAPS, students respond to 32 questions using a 5-point Likert format: 'Strongly Disagree' (1), 'Disagree' (2), 'Neutral' (3), 'Agree' (4), and 'Strongly Agree' (5). The survey was administered online twice during the semester through the web-based Qualtrics system, once at the start of the course and other at the end, to evaluate changes in undergraduate students' attitudes and perceptions. Qualitative data were collected through semi-structured interviews conducted via Zoom. An interview protocol was developed to guide the interview process. Each interview lasted for 30–35 minutes and was recorded with the participants' consent. All recordings were transcribed through the Zoom transcription service.

Data analysis was conducted in two phases. We first conducted a quantitative analysis of the survey data using descriptive and inferential statistics. Descriptive statistics provided the magnitude and direction of attitudinal change across participants. The paired sample t-test was used to determine whether the change in students' pre- and post-survey scores was statistically significant. These quantitative results guided the selection of a potential case for deeper qualitative analysis by highlighting a student who demonstrated meaningful shifts in attitudes across multiple MAPS dimensions. For qualitative analysis, for this preliminary stage, we analyzed the pre- and post-interviews of three participants using the deductive coding approach, applying the seven MAPS categories as *a priori* codes. Three researchers collaboratively coded all interviews through iterative cycles in which each independently coded the transcripts and then met to discuss and resolve any disagreements. Next, we selected a case (Sophia) that enabled detailed descriptions of changes in attitudes, allowing for a nuanced examination of how attitudes evolved across all seven MAPS dimensions. We selected Sophia's case because she exhibited alignment between quantitative change and qualitative evidence, enabling us to illustrate not only *that* attitudes changed but also *how* and *why* they shifted.

Findings

We first provide a summary of the quantitative results showing how our participants' attitudes changed across the seven MAPS dimensions. Building on these patterns, next we present Sophia's in-depth qualitative changes in attitudes across the same seven categories.

Quantifying Changes in Students' Mathematical Attitudes Using MAPS

As suggested by Code et al. (2016), the overall attitudes and perceptions was computed by averaging the scores for all items, excluding Items 19, 22, and 31, while the subscales were calculated based on the set of question items that belonged to each category. The instrument was assessed for internal consistency for the seven subscales and overall instrument using Cronbach's alpha (α). For the subscales, Cronbach's α values for the pre- and post-surveys ranged from 0.35 to 0.81, indicating acceptable internal consistency due to the small number of items in most categories (Code et al., 2016). For the overall instrument, Cronbach's α was 0.89 for the pre-

survey and 0.87 for the post-survey, consistent with the reliability of Code et al.'s (2016) validation study.

As shown in Table 1, Pre-survey means ranged from 2.54 (Interest) to 3.69 (Growth Mindset), indicating a neutral to slightly positive disposition towards mathematics. Post-survey scores showed shifts, with notable positive gains across all subscales, as well as the overall score, and a slight decline in the Sense Making subscale (see Figure 1). These descriptive trends were followed by an inferential analysis to examine whether the observed differences from pre- to post-survey were statistically significant.

Table 1: Descriptive and Inferential (t-test) Statistics for MAPS ($N = 39$)

	Pre-Survey			Post-Survey				
MAPS Categories	Mean	SD	Cronbach α	Mean	SD	Cronbach α	t	p-value
Growth Mindset	3.69	0.69	0.81	3.82	0.53	0.48	–1.15	0.255
Real World	3.48	0.63	0.56	3.81	0.51	0.35	–3.23	0.003*
Confidence	2.66	0.84	0.80	2.97	0.61	0.62	–3.34	0.002*
Interest	2.54	0.94	0.80	2.68	0.90	0.77	–1.14	0.260
Persistence	2.55	0.84	0.78	2.93	0.73	0.71	–3.34	0.002*
Sense Making	3.17	0.61	0.69	3.04	0.51	0.61	1.15	0.255
Nature of Mathematics	3.02	0.60	0.69	3.21	0.56	0.60	–2.07	0.045*
Overall Attitudes and Perceptions	2.98	0.47	0.89	3.17	0.42	0.87	–2.84	0.007*

Note. *p-value < 0.05

A paired sample t-test was used to examine pre-post differences in students' mathematical attitudes and perceptions. Results indicated significant positive differences in the MAPS categories of Real World, Confidence, Persistence, Nature of Mathematics, and Overall Attitudes and Perceptions ($p < 0.05$). No significant differences were found for Growth Mindset, Interest, and Sense Making as shown in Table 1. Thus, the results showed positive changes in students' attitudes and perceptions toward mathematics from the beginning to the end of the course.

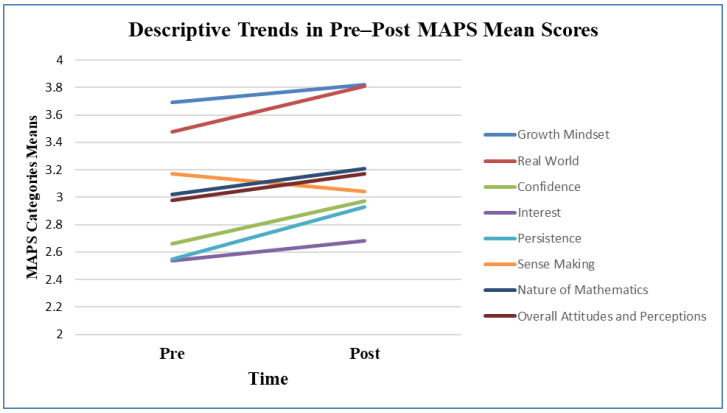

Figure 1: Pre and Post MAPS Categories Mean Scores

Qualitative Changes in Sophia's Mathematical Attitudes and Perceptions

Confidence. Sophia entered the course with low confidence in mathematics, shaped by years of feeling unsuccessful. She reflected that "Growing up, I never wanted to do math, I was never good at math, I've always found it hard to start a problem, or fully grasp the concept of it," a statement that captures both her early avoidance and the deficit-based views she internalized. Despite dedicating "numerous hours" to studying, she still felt that her work "didn't really get to the point that [she] wanted it to," interpreting her struggles as evidence of limited innate ability. Mathematics, for her, "takes a lot of practice, trial and error," and it "is not something that comes easy to her," signifying deeply rooted doubt about her mathematical capacity. After completing the course, however, Sophia's framing of her competence began to shift. Although she continued to acknowledge challenges, she described a growing belief in her ability to make progress, stating, "I feel more confident; I still feel like I'm not the best in it, but I do have that confidence of working through it still." This reflects an important development toward increased confidence and trust in her ability to learn.

Growth mindset. Before the course, she expressed a fixed mindset rooted in comparison to peers who she believed grasped concepts easily. She explained, "I'm not one of those people that look at a problem and know exactly what to do. I always need reteaching," viewing her need for additional time as a lack of mathematical ability. After the course, she articulated a more growth-oriented stance. Although she acknowledged that her challenges had not disappeared, she described a deeper motivation, noting, "I think it's a little bit the same, but I think I'm more motivated to, no matter what math I'm in, to continue to work hard, and not be like, 'oh, I just suck at it'… continue to have the mindset that it is gonna help me, it is gonna be useful, it'll just help me in the future." She now sees mathematics as something worth investing in because of its long-term utility, signaling a meaningful transformation in her mindset.

Persistence. Sophia's persistence has long been apparent. Even before the course, she described pushing herself academically despite negative experiences with mathematics, saying, "I always took the honors classes, because I wanted to push myself, and for that GPA boost." Her persistence, however, was often driven by external motivators such as grades rather than by confidence or internal factors. After the course, her persistence became more intrinsic. She emphasized her motivation to continue working hard regardless of perceived difficulty, because "it is gonna be useful." Her persistence began to stem from a sense of relevance, indicating a shift toward more resilience.

Real-world relevance. In the pre-interview, Sophia made no direct references to mathematics being relevant to real life, and her comments provided little evidence that she viewed math as meaningful beyond the classroom. This changed after the course. She repeatedly emphasized how statistics and mathematics connected to her daily life, her major, and her future career, stating, "Never once have I felt like 'why am I even taking this? I can apply it to my daily life." She identified the concepts learned in class as both familiar and academically important and described course projects as making mathematics personally meaningful. This realization represented a major shift from seeing no real-world relevance to understanding mathematics as applicable, useful, and strongly connected to her future.

Interest. Sophia's interest in mathematics also evolved. Growing up, she "never wanted to do math" and often "hated" it when she did not understand a concept. Although she experienced a slight increase in interest over the year prior to taking the course, her interest remained fragile and heavily tied to her perceptions of success. After the course, however, she expressed more consistent and positive interest, stating, "I've appreciated math more through this course." She

attributed this shift to the instructor, course content, and especially the real-world applications embedded in the curriculum. Her interest moved from conditional and negative toward s appreciation.

Sense making. Before the course, Sophia did not describe how mathematics made sense to her personally; instead, she focused on procedural fluency and the ability to produce solutions quickly as indicators of mathematical competence. After the course, she described mathematics as more meaningful, often emphasizing the role of visuals and context. She explained that although the course incorporated familiar ideas, it used them "in a way that kind of made more sense to [her]; it uses it in a way that has meaning." Visual representations helped her shift away from seeing math as "just numbers," and she contrasted her prior understanding as "surface level" with more technical comprehension. She described analyzing problems, breaking them down, and recognizing multiple solution pathways, as well as improved fluency in interpreting graphs as all part of understanding mathematics.

Nature of mathematics. Finally, Sophia's conception of the nature of mathematics broadened. Before the course, she described mathematics primarily as numbers and patterns, noting that "math is everywhere" and can help people "understand things in a different way." While true, this perspective was relatively limited. After the course, she described mathematics as more visual, interpretive, multifaceted, and connected to computational analysis. She emphasized that the course presented a kind of mathematics she had never encountered before: "It's not like any math that I've taken … it looks at math at a different view." She recognized the discipline as flexible, offering multiple approaches and strategies, and generalized that the course could help others "realize the importance of math."

Taken together, Sophia's journey reflects a strong qualitative shift in mathematical attitudes and perceptions characterized by struggle, self-doubt, and negative emotions to a position defined by motivation, relevance, appreciation, and broadened understanding. Sophia developed confidence, sense-making, and interest that was supported by the course instructor, real-world applications of course content, visual and computational tools, and an expanded view of the nature of mathematics. These illustrate a shift towards positive mathematical attitudes and perceptions. Although she still experiences mathematics as challenging, she increasingly views those challenges as workable, worthwhile, and meaningfully connected to her life.

Discussion and Conclusions

Our study has three major contributions. *First*, our findings confirm that a data science-focused QL course, which differs from conventional mathematics coursework, has the capacity to shift undergraduates' mathematical attitudes and perceptions. Although undergraduates' overall mathematical attitudes and perceptions increased significantly, one striking finding was the decline observed in the *Sense-Making* subscale, which captures "students' perspectives on the nature of their personal mathematical knowledge." However, this decrease was not statistically significant. A plausible explanation for the decrease in sensemaking is that students may not have readily associated the core concepts they learned in STAT 1080 with what they traditionally recognize as "mathematics." As a result, they may have underreported their own sense-making in relation to mathematics, even though they engaged in data-centered reasoning, a core mathematical practice. That is, this behavior could be attributed to students assessing their abilities more conservatively than their actual level of understanding (León et al., 2021). However, despite this decline, the *Nature of Mathematics* subscale showed a statistically significant improvement, suggesting that while students' self-perceptions about sense-making shifted negatively, their conceptualization of what mathematics *is* expanded in productive ways.

The case of Sophia illustrates the ways in which a student's mathematical attitudes can change as a result of engaging in a data science-focused QL course. Notably, Sophia's mathematical confidence grew from initial self-doubt to a stronger sense of self-efficacy, a critical factor for influencing STEM persistence (Lin et al., 2018). Literature notes persistence as also influential for performance in mathematics and overall persistence in STEM (Cohen & Kelly, 2020). For Sophia, although she described herself as an individual with persistence before the course, it was driven by external factors such as grades. After engaging in the course, Sophia developed a sense of persistence shaped by intrinsic factors, such as genuine engagement with the course activities. Although externally driven persistence can motivate students to perform in the short term, it is generally not sustainable. Long-term persistence requires intrinsic motivation (Deci & Ryan, 2012). For Sophia, this course enabled the development of persistence shaped by intrinsic factors. Sophia's reflections on real-world relevance further reinforced this point. Sophia noted that "never once have I felt like 'why am I even taking this?'" highlighting how the authenticity of the course context supported her engagement.

Second, our study promotes a potential novel pathway to STEM persistence for undergraduate learners. Research has shown that positive mathematical attitudes can shape an individual's mathematical well-being (an individual's desire) and STEM persistence (a societal desire). While there exist various research documenting the factors that support learners' mathematical attitudes (e.g., Barkatsas et al., 2009; Stankov et al., 2012; Ahmed et al., 2013), those studies have not focused on quantitative literacy requirements at college, which is a promising avenue for recruiting and retaining students in STEM. Through this study, we have demonstrated that a data-science focused course, that emphasizes computational skills, data literacy, and quantitative competencies, all rooted in real-world applications, can shape students' mathematical attitudes positively. Together with prior research showing the connection between attitudes and STEM persistence, our study implies a potential connection between modernized QL and STEM persistence.

Third, our study contributes to educational research in undergraduate data science education. Although the movement to revolutionize undergraduate mathematics curriculum through the integration of data science was initiated in 2015 (Cassel & Topi, 2016), the educational research to improve undergraduate students' experiences in data science is scarce. That is, within the body of data science education scholarship at the undergraduate level, "there is lack of empirical data and identifiable research questions" and therefore empirical studies in data science education must be prioritized (Dogucu et al., 2025, p. 467). By documenting shifts in undergraduates' mathematical attitudes within a data science learning environment, our study offers an initial response to this pressing research need.

In conclusion, our study shows that a data science-focused QL course, which focuses on engagement with real-world phenomena and computational skills, can support undergraduates' development in mathematics, at least along the attitudinal dimension. It is imperative that the field continues to conduct concurrent research alongside novel curriculum efforts in QL to discern how to best support college learners to develop QL competencies. QL is becoming increasingly more important in today's data-driven society, and the present study contributes to the need for empirically grounded QL curriculum.

This study investigates how image-based versus sound-based data modalities shape high school students' core understanding of machine learning (ML). Using a teaching intervention, students participated in either an image- or a sound-based ML intervention. Data sources included post-survey assessments (n = 51) and follow-up interviews (n = 2). We report findings from a thematic qualitative analysis of an open-response survey item and interviews. Findings revealed modality-based differences in conceptualization: students in the image-based condition more frequently referenced variation, accuracy, and classification, while those in the sound-based condition emphasized variation and the learning process. The image-based focal student recognized classification limits due to overlapping features, whereas the sound-based student viewed ML as a human-driven "feeding" process and believed that enough data would result in perfect accuracy.

Keywords: Machine Learning, Image-Based, Sound-Based, High School

Machine learning (ML) is positioned as an important component of the K–12 curriculum (Touretzky et al., 2019) and is closely linked to pattern recognition and problem-solving practices (Lee et al., 2024; Susanti et al., 2019; Wu & Yang, 2022). Defined as computational techniques that build and refine models to generate data-driven predictions or classifications from prior examples (Alpaydin, 2020), ML holds promise for cultivating students' interest and preparing them for data-intensive futures (Oh et al., 2024). Yet in practice, ML integration in mathematics classrooms remains limited and often superficial. Teachers frequently lack accessible tools and pedagogical support that make core processes conceptually visible to students (Sanusi et al., 2023a; Yue et al., 2022). One overlooked potential factor is the data modality used in teaching ML. Because images and sounds represent information in fundamentally different ways and require distinct forms of interpretation (Adhegaonkar et al., 2026; Kwak et al., 2023), the modality itself may shape how students conceptualize model learning and accuracy. However, little empirical research has examined how different classroom data modalities influence students' developing understandings of ML processes. This study examined students' definition of ML, the role of data in model performance, and expectations of machine effectiveness.

Literature Review

Research on K-12 ML education has grown considerably, with studies showing that students can engage with ML concepts through structured and hands-on experiences even without prior knowledge or strong STEM interest (Sanusi et al., 2023b). Participation in activities such as data labeling, model training, and evaluation supports students' understanding of foundational ML

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

principles (Hitron et al., 2019). In image-based contexts, students recognized how dataset size and balance affect model accuracy and demonstrated early awareness of responsible AI practices (Živković et al., 2025), while also developing understanding of image representation and feature maps (Rajarajan & Martin, 2026). Sound-based experiences similarly produced gains in learning effectiveness, creativity, and engagement when students trained audio classifiers to recognize speech (Hsu & Chen, 2022). Beyond hands-on skills, research suggests that ML learning experiences shape how students conceptualize intelligent systems, with youths recognizing that ML learns from training data and identifies patterns, though their explanations of how learning occurs often remained underdeveloped (Morales-Navarro & Kafai, 2024). As students begin to understand how machines learn, they become more motivated to build mental models for interpreting technology in everyday life (Lin et al., 2020). However, attitudinal and logistical barriers, including disengagement when tasks felt demanding and limited instructional resources, can hinder participation (Karalekas et al., 2023; Alvarez et al., 2022). Collectively, students' understanding tends to remain focused on observable system behavior rather than on the underlying learning processes, and limited empirical work has examined how the type of data used in ML environments shapes students' conceptualizations of how models learn and make classifications.

Method

This study employed a teaching experiment design (Steffe & Thompson, 2000) in which students participated in either an image-based or sound-based instructional condition using Google's Teachable Machine (Google, n.d.), with both conditions sharing identical learning objectives and instructional sequences. Approximately 95% of participants identified as African American, recruited from two high school classrooms open to Grades 9–12. Of 59 survey completions, eight were excluded due to missing or uniform response patterns, yielding 34 image-based and 17 sound-based participants. Eight students were invited for semi-structured post-intervention interviews; two consented, resulting in STUDENT_A (9th grade, image-based) and STUDENT_B (11th grade, sound-based) completing 26 questions covering ML concepts, model learning, accuracy, and ML understanding. Interviews were video recorded, transcribed, and analyzed alongside survey data using thematic analysis (Ahmed et al., 2025), with codes capturing students' ideas about ML processes, data use, and model behavior, which were then grouped into broader themes.

Figure 1: Student Data Collection Procedures for Image- and Sound-Based Machine Learning Model Training

Results

Student Responses on "Why Should We Give the Model Many Pictures/Recordings Instead of Just One?"

The students exposed to the image-based intervention most frequently referenced variation/multiple perspectives (n = 7; 20.6%), followed by accuracy improvement and classification/decision-making (n = 6, 17.6%) (Figure 2). In contrast, most of the students in sound-based intervention either had unclear or no response (n = 5, 29.4%), with the learning process and variation (n = 3, 17.6% each) the next referenced. Overall, image-based intervention elicited more responses related to variation, accuracy, and classification, whereas sound-based intervention elicited more responses reflecting the learning process and variation, while providing limited elaboration.

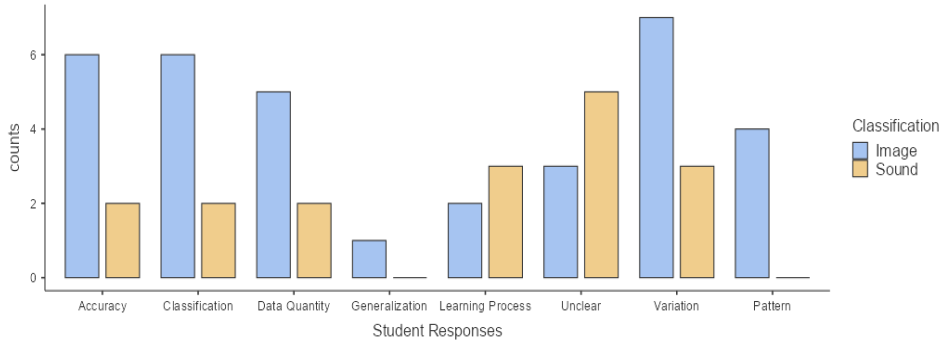

Figure 2: Distribution of Coded Student Responses by Teaching Intervention

Comparative Case Analysis

To further examine how students conceptualized ML across modalities, we analyzed interviews from two focal students: STUDENT_A (image-based) and STUDENT_B (sound-based)

Students' Definition of Machine Learning

STUDENT_A, who was trained on image-based classification, had no prior experience with ML before the intervention. He stated, "*I've never learned about teachable machines before.*" STUDENT_A defined ML as a system for interpreting and "classifying data into various categories. In explaining what ML is, STUDENT_A stated "*ML is basically, uh, how machines, uh, interpret the data we have.*" He continued talking about features of the data that "*a category could be their appearance, their color, based on that, and then we can just, like, sort them, and then we can classify them.*"

On the other hand, STUDENT_B has little experience with ML, having played with a tool while growing up. She said, "*I had a little robot when I was little that we used, and I could teach it how to do things.*" In describing what ML is, the student emphasized repeated "feeding" of the model until it starts to learn by saying, "*you feed it information and it basically gives you information back, and you basically keep feeding it and feeding it until it starts learning.*" The description of the student is that ML is a data-driven, human-fed process that gives an output after constant training.

Role of Data in Model Performance

STUDENT_A viewed model performance as dependent on both the quantity and variety of training data. He emphasized adding more samples and using different types of examples to

improve recognition, validity, reliability, and accuracy. Similarly, STUDENT_B believed that model performance improves when more information is provided, stating that a model trained on 100 samples would outperform one trained on 10. She also emphasized the importance of human involvement in training the model and suggested that factors such as sound waves and speed could influence accuracy in sound-based classification. Both students associated improved model performance with increased training data, although STUDENT_B placed greater emphasis on the role of human training.

Expectations of Machine Effectiveness

STUDENT_A described a machine that can generalize effectively as a model that can easily recognize objects. He stated, "*I would describe it as an effective model which can easily recognize objects… so that, uh, the results can be accurate.*" However, the student thinks that models cannot always be relied on to classify, as some objects can be very similar to each other. He stated, "*I don't think that the model can, like, 100% be accurate because, uh, there can be, like, some objects which are, like, similar.*" In contrast, STUDENT_B believes a model can be perfect if trained over and over. She said, "*I feel like if you keep giving it data of the same thing over and over, it will be*." The student described a model that can generalize effectively as "*you put in the information, and it automatically gives you an answer back.*"

Discussion

Both students described ML as data-driven and referred to variation in training data, which may indicate some awareness that models can benefit from exposure to diverse examples during training (Hitron et al., 2019; Morales-Navarro & Kafai, 2024). Their explanations also differed. STUDENT_A focused more on classification, visual features, and model accuracy, whereas STUDENT_B emphasized the learning process. These findings suggest that data modality influences how students reason about ML and model performance (Morales-Navarro & Kafai, 2024; Wan et al., 2020). The findings also showed that STUDENT_A was able to engage effectively with ML tools despite having no prior exposure, consistent with research suggesting that students can understand ML concepts without prior knowledge or strong STEM interest (Sanusi et al., 2023b). Continued engagement with ML may further support understanding of classification, feature selection, and iterative training (Živković et al., 2025; Hsu & Chen, 2022). Therefore, introducing ML concepts early in K-12 curricula may help strengthen students' understanding and participation in ML. The students expressed contrasting views about model effectiveness. STUDENT_A believed that perfect accuracy is unattainable because similar objects can be difficult to distinguish, reflecting an awareness of the limitations of ML models (Živković et al., 2025; Rajarajan & Martin, 2026). However, STUDENT_B believed that a model could become perfect with enough data, emphasizing the importance of data quantity in improving performance. Providing opportunities for students to compare inputs and observe prediction outcomes may help deepen their understanding of how ML models make decisions. A limitation of this study is that only two students were interviewed, and participants were not randomly selected, which may limit the transferability of the findings.

This study examines how an undergraduate mathematics instructor redesigned her data science course to cultivate learner agency with AI tools. Using our conceptual framing of AI-mediated cognition, we analyzed a course syllabus, instructor reflection memos, and a post-course interview transcript to describe how instructional decisions encouraged students to position AI as a cognitive capacity builder and critical companion. Findings revealed three categories of instructor decision making intended to promote learner agency: making students' thinking visible through AI interactions, revising assessment to promote learner agency, and framing AI-mediated integration within the structure of course assignments. Implications for preserving authority, accountability, and sensemaking in AI-integrated data science courses are offered.

Keywords: Data Science, Artificial Intelligence, Agency

Data science offers a distinctive space for AI engagement in undergraduate STEM education because the requisite statistical thinking is grounded in variability, uncertainty, modeling, and contextual interpretations (Lee & Tran, 2015). Unlike procedural computing tasks or mathematical problems where AI tools execute predetermined steps to produce a known answer, data science projects can grant students opportunities to engage in statistical sensemaking as they use AI tools to assess multiple plausible models and iterate data science experiments on a greater scale. The interpretive character of data science creates a constructive context for examining how undergraduate course instructors can cultivate learner agency when students use AI. Learner agency has been defined as an individual's will and capacity to act (Gao, 2010) in ways that reflect autonomous, self-regulated engagement with learning (Bown, 2009). The level of learner agency that a student exhibits when using AI in data science varies as AI can reshape how models are generated and how decision making is distributed.

Opportunities to learn data science deeply do not develop automatically simply because a student has access to AI tools. Students who show low learner agency might use AI as a tool for creating a model that does not include in-depth reasoning about variables and constraints within statistical models. They might also use AI tools as a shortcut to analyze the data rather than using it as a resource to reason about the data. Students who show high learner agency might substantially engage in decision making about contextual relevance, constraints, coherence with the data, data quality and their analysis aim.

An instructor's decision making about the use of AI in a data science course (e.g., how students engage with AI, what counts as evidence for students' thinking and learning, and how students use and assess AI-generated outputs) can position students with high learner agency

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

who critically evaluate and reflect on AI use, rather than depend on AI for task completion. This study explores the decisions one instructor made to foster students' agency in engaging with AI within a "Statistical Programming in Data Science" course. By describing varying levels of learner agency within a rich data science course context, the mathematics education community can gain insight into how students might delegate reasoning and sensemaking responsibilities to AI (Mouta et al., 2025, Wu et al., 2025). Exploring such delegations can generate insights into how student authority and accountability might be strengthened or diminished with the use of AI.

Methods

To explore instructional decision making and the cultivation of high learner agency within AI-integrated data science learning, we capitalize on our conceptual framing of AI-mediated cognition (Rhodes et al., under review) as our analytical lens. Within this framing (adapted from Cukurova's (2025) work on the interplay of human intelligence and artificial information processing), students can interact with AI in ways that foreground or background different forms of cognition, depending on the activity and their learning goals. The student might use an AI tool as a c*ognitive load reducer, cognitive capacity builder*, or *critical companion*. With *cognitive load reduction*, the student might rely on AI tools in ways that undermine conceptual understanding and limit the potential for an instructor's learning goals to be met. With *cognitive capacity building*, the student prompts AI tools in ways that increase opportunities for metacognition, creative thinking, or self-regulation. When the student positions AI as a *critical companion*, they maintain control and direction while iteratively exploring ideas, testing hypotheses, and co-constructing models with AI. High learner agency is characterized by a keen sense of what the task is asking, what contributions AI can potentially offer in solving the task, how to evaluate the AI's output, what thinking the learner is responsible for, and ultimately, how to merge their own thinking with the AI tool output (Wu et al., 2025).

Context and Instructor Positionality

Statistical Programming in Data Science was the second course in a five-course undergraduate data science sequence. Twenty students enrolled in the course in Fall 2025. All students had completed one prior data science course and several statistics courses, and about one-third had computer science experience or internships. The instructor participant (third author) was an experienced data science educator with a graduate degree in machine learning and a background in learning theory. She designed an AI usage policy that provided flexibility while maintaining alignment with course objectives. She aimed for students to learn how to build data science pipelines (Hardin et al., 2015) through real-world projects and iterative work with messy datasets. Recognizing the varied levels of Python experience of her students, from extensive practice to none, she structured the course to support multiple pathways of engagement including use of AI for coding. Three or four students worked collaboratively on the projects, with AI permitted as a tool to support analysis and exploration.

Data Collection and Analysis

The data science course syllabus provided the first of three data sources for this study, documenting AI usage expectations, opt-out language, assessment structures, and learning goals. Instructor reflection memos documented how teaching a mathematics content course (MATH 414) informed her design decisions for the data science course. Her reflections captured policies regarding AI use, student engagement with AI, and assessment challenges in AI-integrated learning environments. After the first two authors reviewed the reflection memo and syllabus, they conducted a semi-structured instructor interview with the third author. The interview protocol was designed to clarify and deepen understanding of the instructional decisions

articulated in those materials. Questions focused on how prior teaching experiences informed data science course design, how AI-integrated learning was conceptualized, and how assessment structures reflected her goals for fostering learner agency in AI-integrated learning environments. Collaborative qualitative data analysis (Richards & Hemphill, 2018) guided iterative coding, pattern identification, and reflexive interpretation across data sources, with analytic discussions informed by the instructor participant's perspective.

Findings

Analysis of the three data sources suggested three categories of instructor decision making with the aim of fostering learner agency in AI-integrated data science course: (1) Making students' thinking visible through AI interactions rather than restricting AI use, (2) Revising assessment to promote agency within an AI-integrated learning environment, and (3) Framing AI-mediated cognition within course assignments.

Making Students' Thinking Visible Rather Than Restricting AI Use

A central instructional decision was to design tasks where students were required to provide evidence of their interactions with AI. This decision was shaped by instructors' prior experience in teaching MATH 414. She recalled that their reflections often suggested one-shot prompting of AI rather than iterative reasoning and substantive interactions. Detection of AI alone could not resolve her deeper question of "where did their [students] thinking end and the AI's thinking begin?" The MATH 414 students primarily used AI as *cognitive load reducer* who could generate responses for students. Such experiences led the instructor to reflect that simply requiring disclosure of AI use did not necessarily make students' thinking visible in AI-integrated learning environments. This realization prompted a fundamental shift on what counts as evidence of students' understanding and thinking. Rather than attempting to regulate AI use directly, she concluded: "For AI in and out of class, I need to design my assignments in such a way that it's not going to matter what they do with AI outside of class." In designing the data science course, the instructor moved away from student reflection use and instead redesigned course activities so that the AI output was one part of a larger body of evidence of student learning.

Promoting Learner Agency within an AI-Integrated Learning Environment

In the data science course, the instructor promoted learner agency by framing student decision-making through the lens of professional competence. Students were encouraged to use AI in their projects but were also reminded that professional contexts require independent reasoning, justified decisions, and the ability to respond to scrutiny. Project assessments required interpretation and evaluation of the data-model relationship. Students were free to prepare their projects using AI. However, students were required to provide evidence interpreting data, critiquing models, and recommending improvements.

The instructor's new assessment approach shifted AI's role from a *cognitive load reducer* who could support the student in generating a correct response to a *cognitive capacity builder* and/or *critical companion* who interacted with a user to work toward a reasonable response. By requiring students to provide evidence reasoning, the instructor fostered learner agency and gained a window on conceptual sense making. Biweekly project updates required detailed descriptions of data sources, modeling decisions, and emerging challenges. When updates lacked specificity, the instructor reshared her expectation that general "AI-like" responses did not count as evidence of demonstrated understanding. For instance, if an update contained statements such as "This analysis will give us a comprehensive understanding…" the instructor would reply with, "A comprehensive understanding of what data science phenomenon?" implicitly suggesting that

their response (whether it was AI generated or not) lacked sufficient detail. Emphasizing what students would need to do in data scientist job interviews, the instructor set rigorous expectations. "AI can help you, but at the end of the day, it's on you to explain what all of this means… I should be able to ask you anything, and you should be able to answer anything."

Student groups who relied heavily on AI-generated approaches without understanding the data set–model relationships struggled to engage in deep discourse during the oral assessments. In contrast, other groups demonstrated iterative refinement and sustained engagement with their data and models, sometimes with the support of AI. The instructor recalled how students "constantly identified aspects of the data that were causing their models to fail," and considered "what part of the model do we need to change, or is the data set bad?" Their patterns of testing, diagnosing, revising, and justifying suggest that when students positioned AI as a *critical companion*, they retained authority to direct the course of engagement with the AI.

Framing AI-Mediated Cognition within Course Assignments

Examination of the instructor course design shows intentional framing of AI use consistent with the three roles in our conceptual framing: *cognitive load reducer, cognitive capacity builder, and critical companion*. When revising her data science course syllabus for Fall 2025, the instructor evaluated each course learning objective. If AI use rendered an objective obsolete, it was removed. If cognitive demand was preserved with the use of AI, the objective was kept. This evaluation positioned AI not as a tool that lowers cognitive demand, but as one that required deliberate design to ensure cognitive engagement.

AI functioned as a *cognitive load reducer* for students who were stuck with coding because it was not "productive for students to sit in class and not be able to test a model because they didn't have the correct code." The instructor put emphasis toward project pipelining and higher-order reasoning. As a result, she rarely assessed coding syntax, highlighting that students could offload the coding to AI to create more cognitive space for reasoning. The instructor also recalled that several students used AI as a *cognitive capacity builder* to generate practice questions. While the instructor permitted AI use as a study tool to support understanding, she also positioned human feedback as necessary to ensure that students' reasoning aligned with course objectives.

The instructor's decision making also created the potential for AI to serve as a *critical companion* in their projects. She organized students in groups so that AI would not become their sole thinking partner; instead, students could reconcile ideas generated with AI through peer discourse. She emphasized that understanding, not code production, was the goal: "I don't think that coding the algorithm is the only way to understand how the algorithm works or why it's useful for a particular type of problem." AI could assist with coding and analysis, but students remained responsible for explaining modeling choices and interpreting results. The instructor positioned AI not as a substitute for student reasoning but as a tool to support collaboration.

Discussion and Conclusion

Data science, with its emphasis on uncertainty and multiple plausible solutions, offers a productive setting for developing assessments suited to AI-integrated learning environments. These assessments prepare students to think, decide, and justify their work in professional contexts where AI is already part of the expected skill set. The findings of this study suggest that the central challenge for data science instructors is not whether to permit AI use, but how to design learning environments where students' thinking remains visible and students are held accountable for AI use. When instructors require students to justify their analytical choices and engage with AI as a *capacity builder* or *critical companion*, they can position their students as a doers and learners of data science. These findings also challenge the mathematics education

community to redefine what counts as evidence of student learning in AI-integrated learning environments.

Keywords: Data Analysis and Statistics, Statistical Literacy, Habits of Mind, Critical Consciousness

Over multiple decades a consistent call for statistical literacy persists (e.g., Engel, 2017; Gal, 2002; Watson & Smith, 2022), and a call for Critical Statistical Literacy (CSL) emerged (e.g., Weiland, 2017). CSL encompasses making sense of and evaluating statistical messaging from both the production (i.e., generating the statistics) and consumer (i.e., digesting statistical messages produced by others) orientations to better understand the world and issues of power (Weiland, 2017; note that critical implies a nod to critical theories and issues of power). Beyond Gal (2002, 2019), few have investigated how adults engage in statistical literacy or critical statistical literacy. Since we live in a data rich world, with a sea of information at our fingertips, where "data driven" claims permeate our social media streams, CSL research is needed. This study aims to explore if and how adults enact Critical Statistical Literacy Habits of Mind (CSLHM) when interpreting statistical messages from the social media posts.

The CSLHM framework is a set of six habits of mind necessary for critically interpreting statistical information from the media (Bailey & McCulloch, 2023). Habits of mind are thinking behaviors that are employed with ease and frequency (e.g., Goldenberg, 1996). This instrumental multiple case study (Yin, 2018) aimed to better understand adult CSLHM enactment when interpreting statistical messages from the media. The cases were defined using two dimensions: (1) critical consciousness and (2) statistical self-efficacy/knowledge. We administered the Short Critical Consciousness Scale (S-CCS; Diemer et al., 2020; Rapa et al., 2020) and the Current Statistical Self-Efficacy Scale (CSSS; Finney & Schraw, 2003). Since self-efficacy is not necessarily correlated with knowledge, we also included four items from the Intermediate/ Advanced Statistical Literacy form of the Levels of Conceptual Understanding in Statistics (LOCUS) assessment online (Jacobbe et al., 2014). Strong statistical self-efficacy/knowledge was defined as a CSSS sum of 56 or higher with 75% or higher on the LOCUS items. Of the 89 eligible participants (snowball sampling), each was classified into one of four cases (emergent /emergent, emergent/strong, strong/emergent, strong/strong). We randomly selected five participants from each case for the study. The interviews were coded using a priori theoretical coding based on the CSLHM descriptions following DeCuir-Gunby et al.'s (2011) protocol.

Preliminary analysis reveals some distinct trends. Participants with emergent critical consciousness and emergent statistical self-efficacy/knowledge (Case 1) and participants with strong critical consciousness and emergent statistical self-efficacy/knowledge (Case 2) almost never enacted all six CSLHM on a social media post and emergent enactment was more common. In contrast, participants with emergent critical consciousness and strong statistical self-efficacy/knowledge (Case 3) enacted 4 of the 6 CSLHM frequently. Finally, participants with

strong critical consciousness and strong statistical self-efficacy/knowledge evidenced more consistent enactment across posts and more robust enactment.

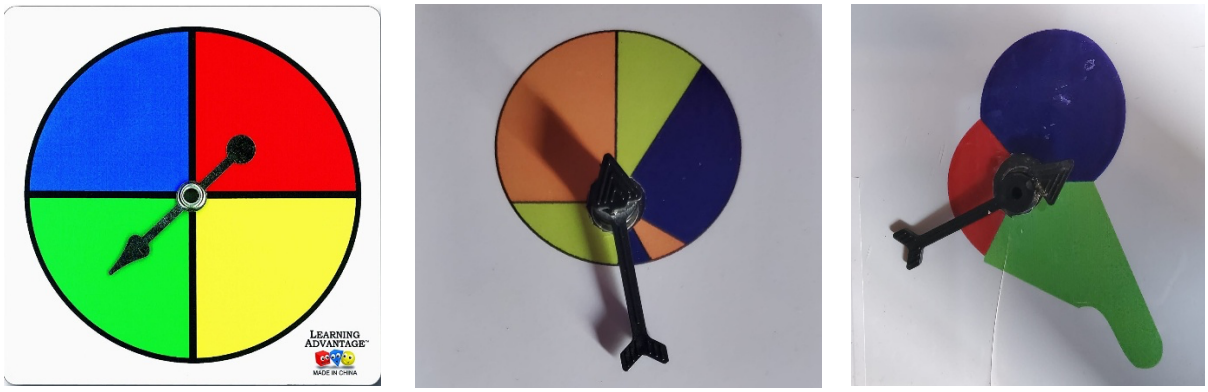
EXTENDING THE SEPT FRAMEWORK TO THE CONCRETE-SYMBOLIC MODE



Modiu Olaguro
Virginia Tech
olaguro@vt.edu

Jesse L. M. Wilkins
Virginia Tech
wilkins@vt.edu

Keywords: Conceptual Development, Probability

Earlier models of probabilistic thinking often treat responses within the Ikonic (IK) mode as incorrect and unaligned with curricula agenda (Tarr & Jones, 1997). Students that operate in this mode ascertain chance through preferences, beliefs, or personal experiences (Amir & Williams, 1999). In contrast, Concrete-symbolic (CS) thinking utilizes symbols typical of formal schooling (Biggs & Collis, 1982). In the Structure of Early Probabilistic Thinking (SEPT) framework, Groth et al. (2021) argued that IK thinking is not entirely homogenous in quality. They classified such responses into either normative compatible or incompatible cycles based on their resource potential for latter modes, specifically sampling. This study investigates whether compatibility extends beyond IK. We ask: (1) How do responses within and across modes differ by normativity? (2) How might normative-compatible reasoning serve as resources for learning?

Data was obtained from seven Grade 10 students on their judgments on three fair spinners: one common (*S1*) and two deliberately perturbed (*S2*, *S3*).

Spinner 1 **Spinner 2** **Spinner 3**

Figure 1: Common, Skewed, and Unusual Spinners

We found that (1) Normative-compatible and incompatible cycles permeate both IK and CS modes, (2) Students frequently judged fairness using area, shape, or center position. Although incorrect for probability, these ideas were legitimate within geometry, and (3) Some students simultaneously drew on IK imagery and CS reasoning, supporting the view that representational modes coexist rather than replace one another. Illustrative excerpts include that *S2* is unfair because "the circle is not in the center and some part are bigger than the other" (CS-incompatible), and *S1* is fair, "90 degree angles; equal chances" (CS-compatible). These excerpts show that incorrect reasoning may contain legitimate disciplinary resources, perturbed tasks reveal conceptual resources hidden by conventional symmetric spinners, and normative compatibility may extend across mathematical domains.

We investigate mathematics capital and its relationship with mathematics teaching and learning experiences, mathematics mindset, mathematics self-efficacy, cultural capital, and subjective social status. Survey data were collected from 927 undergraduate students in Fall 2024. Mathematics capital was modeled as a latent factor in our model with acceptable fit indices via structural equation modeling. The results of our model show that mathematics teaching and learning experiences and mathematics self-efficacy account for most of the variability in mathematics capital, and that subjective social status accounts for variability in mathematics self-efficacy and mathematics teaching and learning experiences. Moreover, cultural capital and mathematics mindset are positively related to mathematics teaching and learning experiences. Overall, mathematics capital has the most associations in our final model.

Keywords: Mathematics Capital, Structural Equation Modeling, Subjective Social Status

Much research has already considered prior achievement in mathematics, mathematical classroom experiences, mathematical dispositions, and how these constructs influence student success in mathematics education (Anthony, 2000; Ashcraft, 2002; Boaler, 2016; Cribbs et al., 2021; Darragh, 2016; Graven & Heyd-Metzuyanim, 2019; Montague et al., 1991; National Council of Teachers of Mathematics [NCTM], 2014). We take a Bourdieusian perspective and aim to consider these constructs jointly (Bourdieu, 1973, 1977, 1984, 1986, 1989, 1990, 1993, 1994, 1997, 2005; Bourdieu & Wacquant, 1992). This approach parallels Archer and colleagues' research in science education (Archer et al., 2012, 2014, 2015). We use a Bourdieusian-style lens to frame and define *mathematics capital*, similar to how *science capital* was defined by Archer and colleagues (2012, 2015), and subsequently widely researched (e.g., Archer et al., 2024; DeWitt et al., 2016; Godec et al., 2017; Godec et al., 2024; King et al., 2015; Kontkanen et al., 2025; Moote et al., 2020; Moote et al., 2021; Nomikou et al., 2017). In prior work, we modeled mathematics capital as a latent factor, constructed a structural equation model (Anderson et al., 2025), and performed a path analysis and confirmatory factor analysis to provide validity evidence for our instrument (Anderson et al., 2024). Our goal in this paper is to extend previous analyses with new data and refine our conceptual framework by adding subjective social status and mathematics identity. We address the following research questions:

1. What variables explain differences in the mathematics capital of undergraduate students?
2. What interrelations, if any, exist between the other measured variables in our model to explain such differences in mathematics capital?

Background and Conceptual Framework

Our framework of mathematics capital extends Bourdieu's (Bourdieu, 1973, 1977, 1984, 1986, 1989, 1990, 1993, 1994, 1997, 2005; Bourdieu & Wacquant, 1992) theorization of capital and Archer and colleagues' (2012, 2014, 2015) application of Bourdieusian capital to the field of science education. Bourdieu (1986) theorized that multiple forms of capital, such as economic, cultural, and social capital, operate within and are valued differently across fields. Fields are understood as structured social spaces in which participants seek to accumulate, exchange, and deploy capital (Bourdieu, 1977). Prior researchers have applied a Bourdieusian lens to the field of science education, empirically examining students' science capital through a theoretical model that integrates scientific forms of cultural capital, science-related dispositions and practices, and science-related social capital (Archer et al., 2015; DeWitt et al., 2016).

We conceptualize mathematics capital as an integral construct within the field of mathematics education (Anderson, 2024; Anderson et al., 2024; Anderson et al., 2025; Anderson & Uhing, 2025). Accordingly, we frame mathematics teaching and learning experiences (MTEAC), mathematics mindset (MMIND), mathematics self-efficacy (MSE), and mathematics identity (MIDT) as established variables within the field of mathematics education that interact with mathematics outcomes, cultural capital (CC), subjective social status (SSS), and mathematics capital (see Figure 1). We include MIDT in our conceptual framework to acknowledge recent research connecting MIDT and mathematics capital (Archer & Mendick, 2024; Valero et al., 2025).

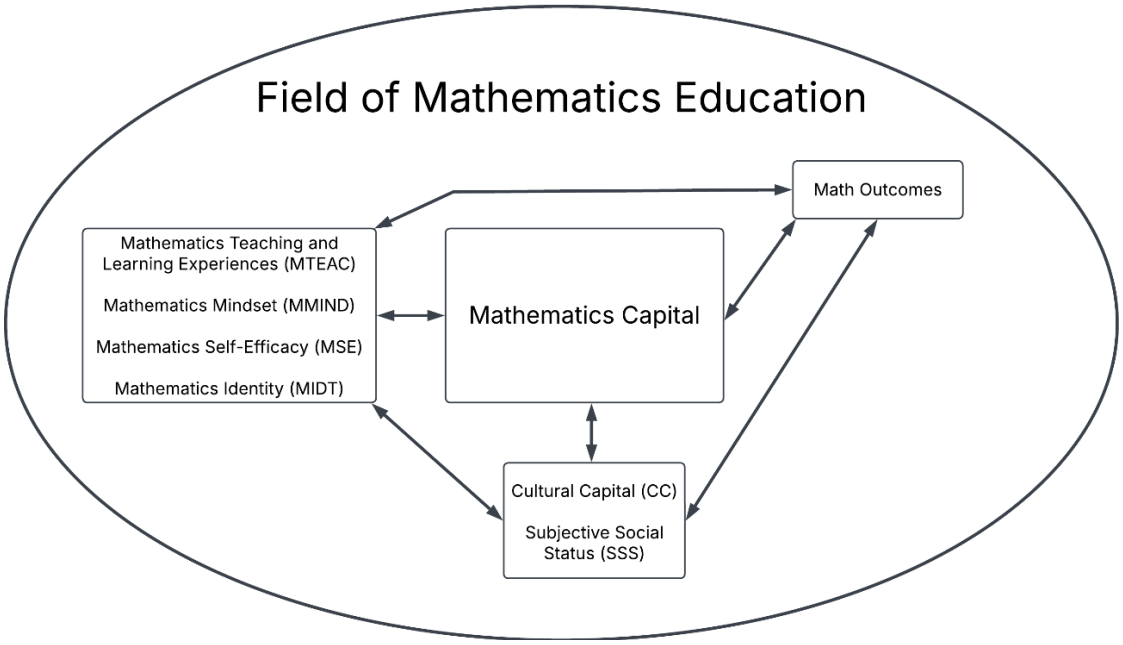

Figure 1: Conceptual Framework for the Field of Mathematics Education

Mathematics Capital

Bourdieu (1989) discussed mathematics capital in relation to access to advanced academic programs and the sciences, noting that within *doxa*, that is, the taken-for-granted, socially accepted cultural norms that often go unquestioned (Bourdieu, 1977), mathematics is positioned as valuable and exclusive, which creates a form of prestige (cf. Bourdieu, 1984). Archer and

Mendick (2024) argued that examining mathematics capital through a Bourdieusian lens is important, contending that such an approach productively challenges dominant orthodoxies within the field (Gutiérrez, 2012). Our work aligns with this perspective by situating mathematics capital within a structural model that examines its relationships with CC, thereby empirically supporting Archer and Mendick's (2024) theoretical claims.

Researchers have also linked mathematics capital to MIDT (Archer & Mendick, 2024; Black & Hernandez-Martinez, 2016; Valero et al., 2025). Black and Hernandez-Martinez (2016) argue that students' access to and activation of mathematics-related capital influence their identification with mathematics and their decisions to pursue mathematically demanding pathways, highlighting how these resources shape both participation and persistence. Archer and Mendick (2024) conceptualize identity and capital as mutually constitutive constructs that mediate participation and engagement in STEM fields. They argue that multiple forms of capital (social, cultural, economic, and symbolic) operate in conjunction with MIDT to shape students' mathematics outcomes, including postsecondary attainment (Archer & Mendick, 2024). Valero et al. (2025) found that mathematics capital shapes students' mathematical engagement (e.g., enrollment in mathematics courses) and their self-perceptions as mathematicians, or MIDT. Jorgensen (2018) highlighted the compounded challenges faced by Indigenous learners in accessing and engaging with mathematics and discussed mathematics capital as a construct that can increase or decrease, although mathematics capital was not explicitly defined. Still, Jorgensen (2018) conceptualized mathematics and school mathematics as a field, aligning with our framing of mathematics education as the field in which mathematics capital operates (Anderson, 2024; Anderson et al., 2024; Anderson et al., 2025; Anderson & Uhing, 2025).

Our research on mathematics capital focuses on defining and describing mathematics capital to disrupt deficit-oriented narratives that label students in mathematics (Anderson, 2022; Anderson, 2024; Anderson et al., 2024; Anderson et al., 2025; Anderson & Uhing, 2025). *We define mathematics capital as the mathematical assets that students draw upon in their everyday lives, which in turn influence their positioning within the field of mathematics education.* We conceptualize these mathematical assets as a constellation of students' collective experiences, dispositions, and intrinsic or extrinsic expectations related to mathematics (del Rosario Zavala & Aguirre, 2024). We contextualize and operationalize mathematics capital within the field of mathematics education by examining its relationships with established constructs in the literature (Anderson, 2024; Anderson et al., 2024; Anderson et al., 2025).

Mathematics Teaching and Learning Experiences

We conceptualize MTEAC as the formal and informal opportunities through which students engage with mathematics across their lifespan (Anderson & Uhing, 2025; Anderson et al., 2024; Anderson et al., 2025). This construct is grounded in the National Council of Teachers of Mathematics' (NCTM) Process Standards (2000), which provides a framework for understanding how students experience and engage with mathematics. We argue that students' engagement, or lack thereof, with these Process Standards reflects their exposure to, and participation in, methods for solving problems, reasoning, communicating, and working with mathematical ideas. The five NCTM (2000) Process Standards (Problem Solving, Reasoning and Proof, Communication, Connections, and Representation) articulate multiple ways students can engage with mathematics, which in turn may enhance their capacity to learn, retain, and develop productive mathematical knowledge and dispositions.

NCTM (2014) reaffirmed and extended the original Process Standards by articulating eight mathematics teaching practices for teachers of mathematics. Whereas the Process Standards

describe how students engage with mathematics, the mathematics teaching practices focus on how teachers enact instruction. Together, these eight teaching practices offer guidance on critical instructional approaches that support high-quality mathematics teaching (NCTM, 2014). Collectively, the NCTM (2000, 2014) publications serve as the theoretical lens through which MTEAC are conceptualized in this study (Anderson, 2024).

To examine students' MTEAC, we initially drew on NCTM's student- and teacher-centered recommendations as well as Ottmar et al.'s (2014) study, which similarly used the NCTM (2000) Process Standards to inform the development of survey items. A key finding of Ottmar et al.'s (2014) work was the identification of a latent factor labeled Instructional Practices for Teaching Mathematics, which measures "best practice in methods for delivering high-quality mathematics instruction to students" (p. 135). Using these theories, we established the reliability of the seven items associated with this construct, yielding Cronbach's alpha values of .81 (Anderson et al., 2024) and .84 (Anderson et al., 2025). For the current study, these items were reused directly from these prior analyses (Anderson et al., 2024; Anderson et al., 2025).

Mathematics Mindset, Mathematics Self-Efficacy, and Mathematics Identity

Drawing on the work of Dweck (2006, 2008) and Boaler (2016), we conceptualize MMIND as individuals' beliefs about their intellectual abilities in relation to mathematics. Individuals with a growth mindset view mathematical intelligence and ability as malleable and believe these capacities can be developed through effort, persistence, and learning, whereas individuals with a fixed mindset perceive mathematical intelligence as an innate and unchangeable trait (Dweck, 2006). Prior research demonstrates that students' MMIND are predictive of mathematics achievement, with students holding a growth mindset consistently outperforming those with a fixed mindset (Dweck, 2008). In addition, MMIND is closely connected to students' beliefs about themselves as learners and their perceptions of the nature of mathematics as a discipline (Boaler, 2016).

MSE is another construct strongly associated with students' mathematics achievement (Hall & Ponton, 2005) and has frequently been examined in relation to MMIND (Cribbs et al., 2021; Anderson et al., 2024). Using structural equation modeling, Cribbs et al. (2021) examined the relationships among MMIND, MSE, and related constructs, including mathematics anxiety and MIDT. In the present study, we employed their instrument that demonstrated validity evidence to measure MMIND (eight items) and MSE (12 items).

Recent research has described the relationship between MIDT and mathematics capital (e.g., Valero et al., 2025), specifically referring to the constructs as "self-reinforcing virtuous loops" (Archer & Mendick, 2024, p. 134). Therefore, we include MIDT in our conceptual model and acknowledge it as a relevant variable within the field of mathematics education. MIDT is defined by Cribbs et al. (2022) as "how students see themselves in relation to mathematics, based upon their perceptions and navigation of everyday experiences with mathematics" (p. 70). In prior work, Cribbs et al. (2015) modified an identity framework that included factors of recognition, competence, performance, and identity. Cribbs et al. (2015) found that students' competence and performance had an indirect effect on students' MIDT, primarily by association with students' interest and external recognition in mathematics. In addition, Cribbs et al. (2021) developed an instrument that demonstrated validity evidence to measure MIDT, which we intend to use in future work.

We differentiate MIDT and mathematics capital by *clarifying a key characteristic of mathematics capital: the daily use and leveraging of mathematical abilities.* While we hypothesize that a person's MIDT and their mathematics capital are related (cf., Archer &

Mendick, 2024; Valero et al., 2025), MIDT is described as a student's self-perception in relation to mathematics, built on their prior experiences with mathematics (Cribbs et al., 2022). Mathematics capital, however, includes an external component: *the person must be utilizing their mathematical abilities.* Furthermore, these *abilities must be valued in the field of mathematics education to provide the person with potential for upward mobility within the field of mathematics education.* In other words, the mathematical ability that a person possesses because of mathematics capital is the type of ability that is valued by others in mathematics education.

Cultural Capital

CC is widely recognized as a construct with varied and sometimes inconsistent definitions across the literature (Dumais & Ward, 2010). In response to these conceptual differences, Dumais and Ward (2010) drew on foundational work by Swartz (1997) and Bourdieu (1973, 1997) to develop survey items designed to operationalize CC. Consistent with their approach, we drew on survey items from Dumais and Ward (2010), Noble and Davies (2009), and Zabihi and Pordel (2011) to inform the development of a set of measures for CC in our own work (Anderson et al., 2024; Anderson et al., 2025).

In prior studies, we included items related to participation in cultural activities, consistent with quantitative research on CC (Dumais & Ward, 2010), as well as items capturing familial support, reading and being read to, and patterns of screen use (Noble & Davies, 2009; Zabihi & Pordel, 2011). Together, these items yielded an acceptable level of internal consistency, with a Cronbach's alpha of .75 (Anderson et al., 2025). A complete list of the 11 items used to measure CC is reported in our earlier works (Anderson et al., 2024; Anderson et al., 2025).

Subjective Social Status

In psychological and educational research, social class is frequently treated as a control variable rather than examined as a central construct or tested as a mediator or moderator of key relationships (Evans, 2004; Liu et al., 2004). Two common approaches to operationalizing social class are objective socioeconomic status (SES) and SSS. SES typically includes indicators such as educational attainment, occupational status, and income, and has been consistently linked to mathematics achievement and educational outcomes (e.g., Sirin, 2005). However, individuals with similar SES profiles often report markedly different perceptions of their social standing, suggesting that objective indicators alone do not fully capture lived experiences of social positioning (Adler et al., 2000; Diemer et al., 2013; Singh-Manoux et al., 2003).

Diemer et al. (2013) discussed SSS as capturing how individuals internalize structural inequalities and make sense of their opportunities and constraints within social systems, distinguishing it conceptually from SES. Because SSS reflects perceived access to valued resources and recognition, it has been shown to predict a range of educational, career, and health-related outcomes beyond objective socioeconomic measures (Adler et al., 2000; Diemer et al., 2013; Singh-Manoux et al., 2003). From a Bourdieusian perspective, SSS can be understood as an indicator of how individuals perceive their position within the field and their capacity to mobilize capital. In mathematics education, students' perceived social standing may shape their sense of legitimacy in mathematical spaces, their interpretation of instructional experiences, and their use of mathematical assets as capital (Archer et al., 2012; Bourdieu, 1986; Nasir & Hand, 2006). Accordingly, we include SSS in our model to examine its associations with mathematics capital, MSE, MTEAC, and CC, providing insight into how perceived social positioning relates to variation in students' mathematical trajectories (Adler et al., 2000; Diemer et al., 2013).

Methods

Participants and Data Collection

Participants in this study were college students enrolled in a psychology, teacher education, or mathematics course at a public, metropolitan university in the Midwestern United States in Fall 2024. A Qualtrics survey was distributed via email to all students enrolled in a mathematics course. We received 1,168 responses from 4,555 students, for a response rate of 26.2%. Only participants who completed the entire survey were included in the analysis, for a total of 927 participants and a response rate of 20.8%.

Variables

Mathematics capital, MTEAC, MMIND, MSE, CC, and SSS were the six variables that we included in this study. Participants responded to questions using a 5-point Likert scale for mathematics capital, MTEAC, MMIND, and MSE. For SSS, participants responded using an adapted Cantril Ladder (Cantril, 1965; Levin & Currie, 2014) that allowed them to select whole numbers from 1 through 10 to rate themselves, their family, and families in their neighborhood growing up in terms of social status (cf. Graham & Ciciurkaite, 2025; Stanford SPARQtools, n.d.). Existing instruments for MMIND and MSE (Anderson et al., 2024; Anderson et al., 2025; Cribbs et al., 2021) were used with established validity evidence. Further, existing instruments for MTEAC (Anderson et al., 2024; cf. Ottmar et al., 2014) and CC (Anderson et al., 2024; Anderson et al., 2025; cf. Dumais & Ward, 2010; Noble & Davies, 2009; Zabihi & Pordel, 2011) were used, which also had established reliability. For the SSS variable, our measurement instrument was based on prior research on SSS and established methodologies (Cantril, 1965; Diemer et al., 2013; Graham & Ciciurkaite, 2025; Krieger et al., 1997; Levin & Currie, 2014; Stanford SPARQtools, n.d.). Our Cronbach's alpha values were as follows: MTEAC $\alpha = .84$, MMIND $\alpha = .92$, MSE $\alpha = .95$, CC $\alpha = .79$, SSS $\alpha = .75$. Our prior instrument to measure mathematics capital showed validity evidence, which we have discussed in our prior work (Anderson et al., 2024; Anderson et al., 2025). Specifically, we reported a Cronbach's alpha value of 0.94 (Anderson et al., 2024) and we reported an omega value for mathematics capital modeled as a latent factor of 0.90 (Anderson et al., 2025). See prior works for the list of survey items (Anderson et al., 2024; Anderson et al., 2025).

Analysis

We collected data using Qualtrics, then exported these data to SPSS (Ver. 29). Initial descriptive analyses were performed as an initial analysis and assessment of the survey measures. We then created a latent factor for mathematics capital using M-Plus Ver. 7 (Muthén & Muthén, 2012). Next, using a path analysis, we examined the associations between the study variables to the latent factor of mathematics capital (Kline, 2015). Indirect effects of the associations with mathematics capital were delineated. The aim of these analyses was to explain differences in participants' mathematics capital.

Results

First, the latent factor of mathematics capital was tested. An acceptable model fit was obtained for the six indicators loaded onto a single factor by adding one association between the errors of two of the items (cf., Anderson et al., 2025). All of the factor loadings were acceptable (i.e.: positive and significant; loadings $\geq .76$). The resulting model was a good fit to the data ($\chi^2_{(8)} = 51.30$, $p < .05$, CFI = .99; RMSEA = .08, SRMR = .01). In general, the study variables were related to each other significantly in the expected directions. Notably, the two strongest associations with mathematics capital were MSE ($r = .82$, $p < .01$) and MTEAC ($r = .41$, $p < .01$). See Table 1 for a complete review of the zero order correlations.

Table 1: Zero-Order Correlations Between the Study Variables.

Variables	1.	2.	3.	4.	5.	6.
1. Mathematics Capital (latent)	-	.12**	.03	.31**	.82**	.41**
2. SSS	.12**	-	.20**	.01	.15**	.14**
3. CC	.03	.20**	-	.09**	.05	.34**
4. MMIND	.31**	.01	.09**	-	.48**	.17**
5. MSE	.82**	.15**	.05	.48**	-	.35**
6. MTEAC	.41**	.14**	.34**	.17**	.35**	-

Note. * p < .05, ** p < .01.

Given the strong associations between the latent factor of mathematics capital with both MSE and MTEAC, a structural equation model using both as principal predictors of mathematics capital was created. As such, SSS, CC, and MMIND were included in the model, with their effects on mathematics capital being indirect, where the direct relationship was seen through MSE or MTEAC. See Figure 2 for the full structural equation model.

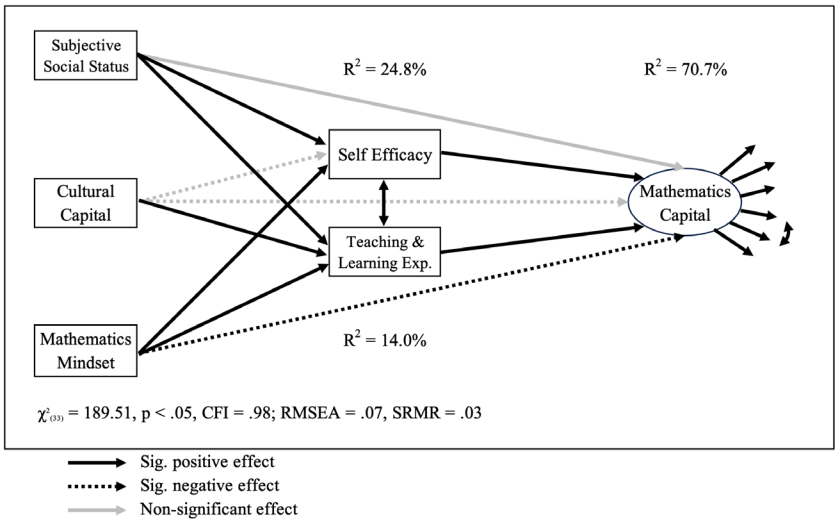

Figure 2: Full Structural Equation Model with Mathematics Capital as a Latent Factor

There were several relations between the other variables with MSE and MTEAC (replicating the correlation matrix). More interesting is that part of the associations between these variables were significantly indirectly through MSE and MTEAC. Specifically, the association between SSS with mathematics capital was indirectly through MSE ($\Delta\beta = .12$, $p < .05$). Moreover, the association between MMIND with mathematics capital was also indirectly through MSE ($\Delta\beta = .39$, $p < .05$). MTEAC accounted for indirect effects of SSS ($\Delta\beta = .01$, $p < .05$) and MMIND ($\Delta\beta = .02$, $p < .05$) as well, but more weakly than MSE. In other words, once MSE and MTEAC were included in the model, the effects of SSS and MMIND were solely through them. All told, the predictors accounted for 70.7% of the variability in mathematics capital, and the final model remained a good fit to the data ($\chi^2_{(33)} = 189.51$, $p < .05$, CFI = .98; RMSEA = .07, SRMR = .03).

Discussion and Implications

Our research aims to define and describe mathematics capital, quantitatively and qualitatively, similar to the way past researchers have developed science capital (Archer et al., 2012; Archer et al., 2014; Archer et al., 2015; Archer et al., 2024; DeWitt et al., 2016; Godec et al., 2017; Godec et al., 2024; King et al., 2015; Kontkanen et al., 2025; Moote et al., 2020; Moote et al., 2021; Nomikou et al., 2017). Thus, this research is in direct response to the call for more studies to understand the nature of the mathematics capital, how it interacts with MSE, and how it affects undergraduate students' outcomes and/or experiences in mathematics education (Anderson et al., 2025). In prior work, we noted that the strongest observed association was between MSE and mathematics capital (Anderson et al., 2025). In this study, we replicated this observation and refined our analyses to better understand the relationship between these two variables. Based on our model and setting MSE and MTEAC as prominent predictors, we note that these variables are relevant to describing differences in undergraduate students' mathematics capital. MMIND, CC, and SSS impact mathematics capital indirectly through MSE and MTEAC. These results show how different variables can predict mathematics capital, both directly and indirectly, which is critical as we continue to investigate mathematics capital as a construct in mathematics education and aim to develop interventions to impact individual undergraduate students' mathematics capital in future work.

Prior achievement in mathematics has been widely researched along with its relationship to individual student outcomes (Anthony, 2000; Ashcraft, 2002; Boaler, 2016; Cribbs et al., 2021; Darragh, 2016; Graven & Heyd-Metzuyanim, 2019; Montague et al., 1991; NCTM, 2014). Certainly, mathematics capital considers prior achievement in mathematics as a component of individual student outcomes in mathematics (Anderson & Uhing, 2024). However, mathematics capital is more dynamic and comprehensive than prior attainment (Anderson, 2024; Anderson et al., 2024; Anderson et al., 2025; Anderson & Uhing, 2025; Archer & Mendick, 2024). For these reasons, we argue that developing a deep understanding of mathematics capital is critical in learning about differences between student outcomes in mathematics. We theorize mathematics capital as a framework for mathematics educators to provide interventions in mathematics for adoption or adaptation based on individual learner's mathematics capital.

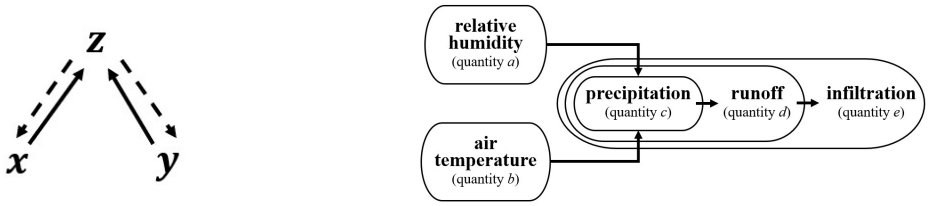
Research shows middle school students can engage in multivariational reasoning by coordinating multiple changing quantities. This report extends that work with empirical evidence from a case study of two middle school students working through a faucet task sequence. We examine how two students each constructed and used two different multivariational structures. We describe the structures each student developed and how their structures influenced how they responded to follow-up prompts. We conclude with methodological and instructional implications for designing tasks that support quantitative and multivariational reasoning and using these tasks in instruction.

Keywords: Multivariation, Middle School Education, Mathematical Representations, Graphs



A growing body of research has emphasized how students' constructing and reasoning about quantities that change together can form a powerful basis for their mathematical development (see Thompson & Carlson (2017) for a review). Whereas much of this work has focused on students' constructing and coordinating two quantities (i.e., *co*variational reasoning; Carlson et al., 2002; Saldanha & Thompson, 1998), a growing body of research has begun to explore students' constructing and coordinating three or more quantities (i.e., *multi*variational reasoning (MV); Jones, 2022). Several researchers have shown that students as young as middle school (Ellis et al., 2015; Panorkou & Germia, 2013; Paoletti et al., 2025) can engage in MV reasoning as they construct and coordinate multiple quantities in situations that entail numerous quantities.

As students engage in covariational and MV reasoning, they construct quantitative structures that help them understand the interrelationship between quantities (Thompson, 1990, 1993). For example, Thompson (1993) described different structures students can construct when comparing the relative heights of two brother/sister pairs from different families (e.g., first comparing siblings within families and then comparing across families, versus separately comparing brothers and sisters across families and then comparing the differences). In this report, we leverage research on students' MV reasoning (Jones, 2022; Panorkou & Germia, 2023) to address the research question: *What multivariational structures do middle school students develop in the context of the faucet task, and how do they use them to address novel prompts?* Addressing this question, we characterize the different MV structures two middle-school students developed as they made sense of a faucet context across three sessions in a larger teaching experiment focused on their quantitative and covariational reasoning. Further, and going beyond extant research, we highlight how differences in their MV structures played a role in their responses to follow-up questions. We conclude with implications for researchers, teachers, and curriculum developers.

Literature Review and Theoretical Background

Extending research on students' quantitative and covariational reasoning (Thompson & Carlson, 2017), Jones (2022) defined MV reasoning as a student's reasoning about situations in which more than two quantities change in relation to one another. He distinguished different ways students relate quantities: when inputs vary separately (*independent MV*), when changes are mutually linked (*dependent* MV), and when one change feeds into another (*nested MV*). Jones (2022) described the mental actions of ten multivariable calculus students reasoning about multi-quantity situations. For example, in reasoning about $z = x^2 - y^2$, one student conceived an *independent* MV relationship and explained that x and y can each change (even at the same time), and that those changes together determine how z changes, without x and y being dependent on each other (Figure 1a).

(a) Independent MV Reasoning (b) Integrated MV Reasoning

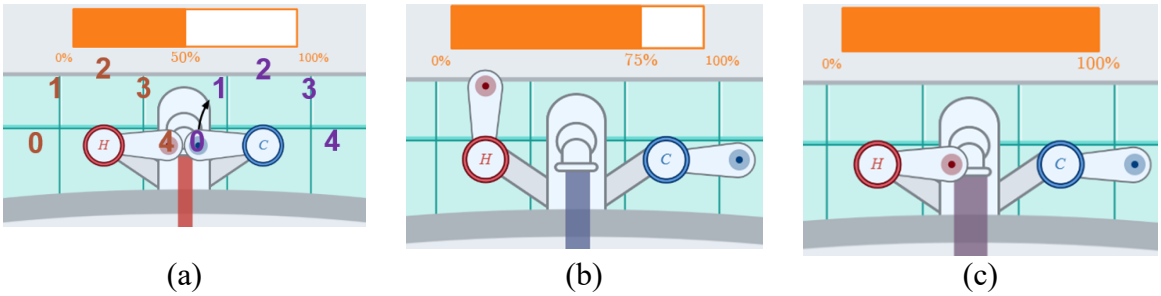

Figure 1: (a) Independent MV Reasoning (adapted from Jones, 2022, p. 6) and (b) Integrated MV Reasoning (adapted from Panorkou & Germia, 2023, p. 21)

Panorkou and Germia (2020, 2023) showed that MV reasoning is not limited to college students. They worked with sixth-grade students in whole-class design experiments using science simulations (e.g., water cycle, rock cycle, sea level rise). They found that students could coordinate complex relationships among multiple changing quantities, and identified several types of MV reasoning, including independent and nested MV, as described by Jones (2022). They also introduced *integrated* MV reasoning, in which students combine multiple MV categories. For example, in a water cycle context, a student used integrated MV reasoning by combining independent and nested MV: the student first treated relative humidity and air temperature as two independent quantities that together lead to "a lot of rain and a lot of runoff," (p. 21), then linked a nested chain by explaining that more rain produces more runoff, and increased runoff leads to more water going into the aquifers (infiltration; Figure 1b).

Whereas Jones (2022) and Panorkou and Germia (2020, 2023) described students' MV reasoning, we would characterize their descriptions (such as those in Figure 1) as MV structures (Thompson, 1993). A MV structure is a researcher's explanation of a student's meanings for relationships between quantities. Of relevance here, we focus on *independent* (Jones, 2022; Panorkou & Germia, 2023) and *integrated* (Panorkou & Germia, 2023) MV structures. We explain these structures in our task context, the faucet (e.g., Figure 2a).

In this task, we were particularly interested in students' abilities to coordinate the relationship between the amount each knob was turned and the percentage of water leaving the faucet with respect to the maximum amount possible. To support students' attention to the amount each knob is turned, we defined a full knob turn (i.e., 180 degrees from left to right) as comprised of four quarter knob turns (QKT; Figure 2a). With this numbering system, a knob pointing left (off) can be described as 0 QKT while the knob pointing right (all the way on) can be described as 4 QKT.

Leveraging the number of Hot QKT and Cold QKT, we asked students to consider how these quantities related to the total percent of water leaving the faucet (hereafter *percent of total water*), because there was a maximum of 8 QKTs, a knob at 4 QKT contributed 50% of total water. We intended the orange bar (Figure 2) to represent the percent of total water.

(a) (b) (c)

Figure 2: Faucet Task Applet with: (a) 4 Hot QKT, 0 Cold QKT, 50% of Total Water; (b) 2 Hot QKT, 4 Cold QKT, 75% of Total Water; and (c) 4 Hot QKT, 4 Cold QKT, 100% of Total Water

A student engages in independent MV reasoning when they coordinate how two quantities, which change independently of each other (i.e., input quantities), influence a third quantity (Jones, 2022; Panorkou & Germia, 2023). For example, in this context, a student may reason that the number of Hot QKT and Cold QKTs added together constitute a new quantity, Total QKT (Figure 3a). Importantly, the student treats Hot and Cold QKT as varying independently, and both contributing to the magnitude of Total QKT.

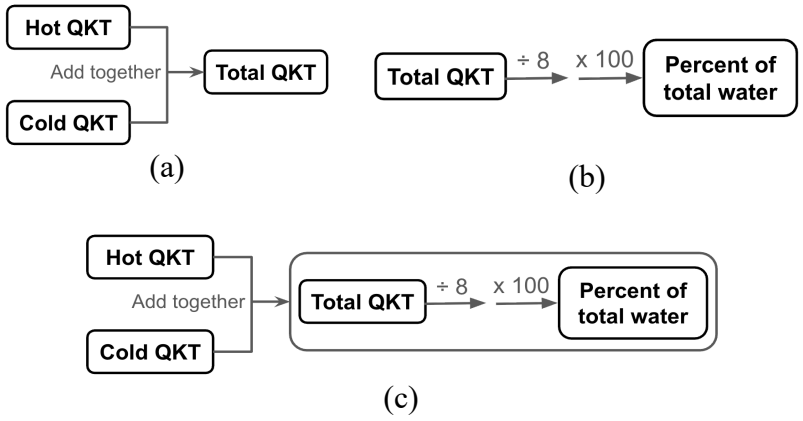

Figure 3: (a) Independent MV Structure, (b) Causal Covariational Relationship, and (c) Integrated MV Structure for the Faucet Context

A student engages in integrated MV reasoning (Panorkou & Germia, 2023) when they coordinate at least three quantities by linking quantitative structures. For example, a student may understand they can divide the Total QKT by eight and then multiply that result by 100 to obtain the percent of total water (Figure 3b). Such a relationship constitutes a causal covariational relationship, in which changes in one quantity cause changes in another quantity (Thompson & Thompson, 1996; Paoletti et al., 2015). Such reasoning is akin to Jones' (2022) nested MV

structure, although it involves only two quantities. Finally, the student can creates an integrated MV structure by linking these structures in such a way that the three focal quantities of Hot QKT, Cold QKT, and percent of total water are linked (Figure 3c). Additionally, this structure includes another quantity (Total QKT) introduced by the student in the process of establishing the integrated MV structure.

In this study, we characterize the different MV structures that two middle school students constructed in the faucet context. We also highlight how their different MV structures influenced their reasoning when addressing novel follow-up tasks in the faucet context.

Methods

In this report, we use a qualitative case study (Yin, 2018) to characterize the MV structures two middle school students developed and used in the aforementioned faucet context. We use data from a teaching experiment (Steffe & Thompson, 2000) that we conducted with two seventh-grade students with the self-selected pseudonyms Lil Man Man (LM) and Michael Jameson (MJ). The students had worked with the teacher-researcher (TR; the second author) in sixth grade to develop meanings for various types of covariational relationships (e.g., Paoletti et al., 2025). In this follow-up study, we were interested in exploring how students might reason about novel situations involving more complex relationships involving three or more quantities.

The TR conducted twelve, 35–40-minute sessions that were held approximately weekly with LM and MJ (typically paired, but at times individually). We video- and audio-recorded each session to capture their utterances and gestures. We digitized all their written work and screen-recorded their computer activity. However, for this report, we focus only on the task sequence used in Sessions 6–8 (Table 1) involving the faucet context. In Sessions 6–7, we focused on the MV structures students constructed to make sense of the faucet context. In Session 8, we explored how MJ and LM's MV structures influence their reasoning about graphs that we intended to represent all three focal quantities from the faucet context (Figure 4b).

Table 1: An Overview of the Teaching Experiment Sessions Over Two Years

Session	Participants	High-level Goal
1–5	LM, MJ	Construct the relationship between two quantities (Base length and Side length) and describe them via graphs within the context of playpens.
6–7	LM, MJ	Construct and reason about three quantities (Hot knob turns, Cold knob turns, and total percentage of water coming out) within the faucet task in Desmos.
8	LM	Make sense of the meanings for two graphs (Figure 2b and 2c; Figure 2b was introduced first) and connect them with specific situations within the context of the faucet task.
9	LM, MJ	
10–12	LM, MJ	Extend to relative percentage problems in the faucet context.

Analysis

Consistent with the teaching experiment methodology (Steffe & Thompson, 2000), we analyzed the data using conceptual analysis, by "building models of what students actually know at some specific time and what they comprehended in specific situations" (Thompson, 2008, p. 45). Specifically, we looked for evidence of the MV structures LM and MJ were developing. We

did this by identifying instances in which each student made connections between how the three quantities in the task varied, comparing these instances over time to make inferences about the structures they were developing. We also looked for instances in which we inferred that the MV structures we identified influenced their activity in constructing or interpreting graphical objects (i.e., points and lines) representing these quantities. At times, we revised our inferences about their MV structures after observing additional activity, which supported a new model of their mathematics that was more explanatory than our original descriptions. Through this iterative process, we constructed explanatory models of each student's MV structures.

Results

LM and MJ each developed integrated MV structures, but these structures differed, and they used them in different ways across Sessions 6–7. Further, these structures influenced the way they reasoned about a novel graph representing the focal quantities in Session 8.

MJ developed the integrated MV structure discussed earlier (Figure 3c). He treated Hot QKT and Cold QKT as two quantities whose sum formed a new quantity, Total QKT. Dividing Total QKT by 8, then multiplying by 100, produced the percent of total water.

LM also developed an integrated MV structure. He understood each knob contributed up to 50% of the total water. Using this meaning, he knew he could divide the number of Hot or Cold QKTs by 4, then multiply by 100 to determine the percent of total water contributed by *that* knob (a causal covariational relationship; Figure 4a). He would then add these values to determine the percent of total water. Each percent changed independently, so this represents an independent MV structure (the "Add together" link in Figure 4b). By combining these structures, LM constructed an integrated MV structure (all of Figure 4b) that was distinct from MJ's structure. Next, we highlight key moments illustrating LM's and MJ's MV structures and how these structures influenced their reasoning in multiple instances.

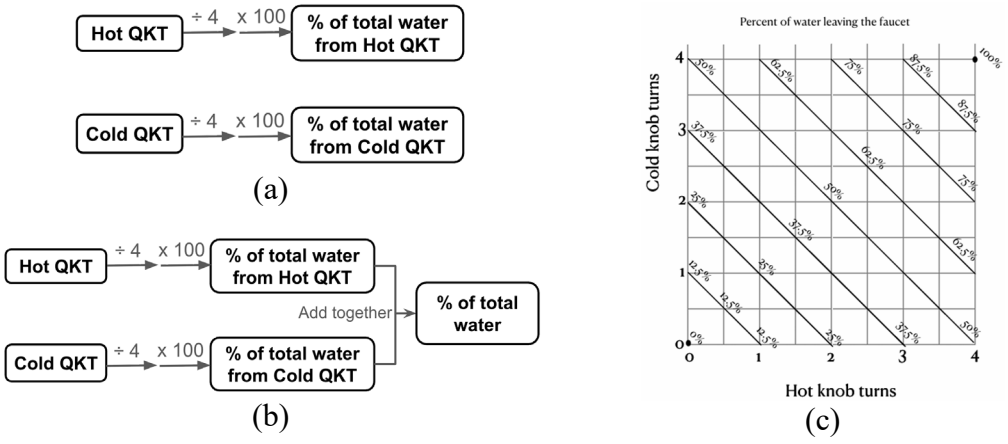

Figure 4: (a–b) LM's MV Structure and (c) a Graphical Representation Showing the Three Focal Quantities

Fixing One Knob: Different Structures Result in Different Reasoning

In Session 7, the TR asked each student to consider how the percent of total water changed as one QKT varied while the other remained fixed. MJ and LM provided different descriptions of how the two quantities changed, and we infer these differences stemmed from their distinct MV

structures. We first present each student's activity, then our analysis of how their structures influenced that activity.

When the TR prompted MJ to consider how the Cold QKT and percent of total would change with the Hot QKT fixed at 2, MJ responded, "It's going lower or higher [as the cold knob is turned off and on]." When asked for a specific percentage range as Cold QKT increased from 0 to 4, he specified, "It's gonna go higher." MJ's response provided evidence that he understood the directional relationship between the quantities (e.g., as Cold QKT increases, the percent of total water also increases), though he did not provide specific numerical values for the percentage of total water.

In contrast, when the TR asked a similar question to LM, he argued the percent of total water would change by 50%. Specifically, when asked how the percent of total water would vary as Hot QKT varied with 1.6 Cold QKT fixed, LM immediately dragged the cold knob to 1.6 QKT. However, the applet still showed 2 Hot QKT, which meant 45% of total water was shown. Thinking that the situation currently represented 1.6 Cold QKT and 0 Hot QKT, LM stated, "I think it's going to be anything between 45 and [*paused for 8 seconds*] 95." In the moment, the TR inferred that LM assumed the applet was showing 0 Hot QKT, so he asked LM to move the hot knob. As LM dragged the hot knob, he realized that with 0 Hot QKT and 1.6 Cold QKT, there was 20% of total water. LM then revised his answer, saying, "anything between 20 and 70[%]."

We infer that LM anticipated that Hot QKT changing from 0 to 4 would change the percent of total water by 50% (i.e., initially anticipating that the range will be 45–95%, then revising it to 20–70%). Based on his later activity, we infer that this meaning also informed his reasoning about how changes in Cold QKT would affect the percent of total water. We infer that LM's MV structure (Figure 4b), entailing each knob contributing a maximum of 50%, led to his conclusions. In contrast, for MJ, the task did not entail finding the sum of QKT as an intermediate step to determine the percent of total water. We infer the lack of this intermediate value could explain why MJ did not provide specific percent values, focusing instead on the directional relationship between two quantities. His MV structure (Figure 3c) required determining the Total QKT before determining percent of total water values.

Fixing the Percent of Total Water and Varying Cold and Hot Turns

We also observed differences in how the students responded to questions with a fixed percent of total water, which we infer were related to their respective MV structures. The TR asked, "Say we want the water to always be 50% coming out, but you can change the hot and the cold knobs at the same time. How are the cold and hot knobs going to change?" MJ responded first, and without moving the knobs. He said, "both [knobs] have to be two, or two turns. Or it could be three on, one turn … So, it could be four in all. So long as [it's] equal to four in all." The TR probed further, "Say I'm taking the cold knob from zero to four, what do I have to do to the hot knob?" MJ immediately responded: "Take it to zero … at the same time, it would have to go left." Across these responses, we infer that MJ understood that for 50% of total water, the number of Total QKT must sum to four (Figure 3c). He was able to leverage this meaning both for individual values (2 and 2; 3 and 1) as well as to reason covariationally; he argued that the two knobs needed to turn in opposite directions to maintain this sum of "four in all," which is consistent with his MV structure (Figure 3c).

We note that LM was able to understand MJ's arguments, and adopt them in the moment (e.g., arguing, "So long as the turns equals four. It's like four turns is like half of eight, and 50%

is half of 100."). However, LM did not spontaneously adopt this reasoning in the subsequent activity, instead relying on his own MV structure.

Determining One Quantity Given the Other Two: A Novel Graph

Given the productive but different MV structures each student exhibited in Session 7, we were interested in exploring how each student might interpret graphs representing the three quantities (Figure 4c). Hence, in Session 8(a/b) the TR worked individually with each student to explore how they may leverage their MV structures to interpret this novel graph.

During Session 8a, the TR provided LM the graph in Figure 4c and asked what percentage of total water would correspond to 2 Hot QKT and 1 Cold QKT. Instead of using the graph, LM quickly responded, "Maybe like 35[%], because like 2 [QKT] equals, like, when it's at 2 [QKT], it's 25[%]. And then 1 [QKT] is like, uh, I don't know … 15[%]? Wait, wait, I think it's like 12.5%. 25 divided by 2." Consistent with his MV structure (Figure 4a), LM described using the number of each QKT to determine the percent of total water contributed by that knob (2 QKTs contributes 25%, and 1 QKT contributes 12.5%). Using this inference, LM correctly determined the answer of 37.5% of total water by adding these two percent together. In follow-up prompts, whenever the TR provided two integer QKT values, LM would engage in similar reasoning.

In contrast to LM, MJ's response to this type of question in Session 8b showed a specific focus on the Total QKT. The TR's first asked, "What if we have 1 hot turn and 2.5 cold turns, what will the percent be?" After thinking for 10 seconds, MJ responded:

> It's right here [*marked a point in the graph in the region between 62.5% and 75%*]. I think it's up there because four full turns and two turns, it's 75%, so for 3.5 [turns] and on, I would say like right between … I would say actually near 50% because I'm saying, wait, no I changed my mind. 62.5[%], I decide that because 3.5 [turns] is near half, well near four [turns].

We infer that MJ connected 6 Total QKT to 75% of total water, then tried to relate 3.5 Total QKT to 6 Total QKT by selecting a percentage below 75%. He further refined his answer by comparing the 3.5 Total QKT with 4 Total QKT ("actually near 50%"). However, he ended up choosing a value above 50% of total water rather than approximating a value below 50% of total water. We conjecture the decimal value of Total QKT (3.5) may have created a complexity for MJ's desire to determine the exact percent. However, when later asked to determine the number of Cold QKT if there were 75% of total water and 3 Hot QKT, MJ immediately responded that there would be 3 Cold QKT. The TR asked "How did you figure that out? That was fast." MJ responded, "Because I remember, with 4 and 2 equals 6, so all I know is you have to equal 6 to equal 75%." Once again, MJ relied on his integrated MV structure (Figure 3c) to relate the percent of total water to the Total QKT, with Total QKT determined by the sum of Hot and Cold QKT.

Discussion

Addressing the first part of our RQ (What are the MV structures that middle school students develop?), we characterized two different MV structures that students constructed when conceiving a relationship between three focal quantities in a faucet context. Although both students constructed an integrated MV structure (Panorkou & Germia, 2023) that entailed both independent MV (Jones, 2022) and causal covariation (Thompson & Thompson, 1996), they did so in different ways. MJ's structure emphasized finding the number of Total QKT as the sum of the Hot and Cold QKT (independent MV structure) and then relating the Total QKT to the percent of total water (a causal covariational structure). In contrast, LM's integrated MV

structure first entailed separately determining the percent of total water contributed by the Hot QKT and the Cold QKT (two separate causal covariational structures) and then summing these to determine the percent of total water (an independent MV structure). In addition to characterizing novel MV structures, this report contributes to the literature on students' MV reasoning by exploring how these structures influenced students' activity addressing other prompts.

Addressing the second part of our RQ (how students leverage MV structures?), we highlighted how these structures influenced students' responses to tasks relevant to the faucet context; each structure had affordances and constraints when addressing certain follow-up prompts. For example, MJ's structure allowed him to reason covariationally about the relationship between Hot and Cold QKT for a fixed percentage of total water, as he understood the Total QKT would need to remain fixed. However, his structure was less productive when the TR tasked him to determine a range of percent values for one knob varying and the other fixed. LM's structure allowed him to quickly determine various relationships when given an integer number of QKT (e.g., determining percent of total water for a given number of Hot and Cold QKT; reasoning about a range of percent of total water with one knob fixed and the other varying). However, his structure was not as productive to reason about how the number of Hot and Cold QKT covary for a fixed percent of total water.

We highlight that though we presented our inferences about each student's MV structures and implications of these structures, our inferences about their structures were informed by the overall collection of their activity, which is consistent with retrospective analysis in the teaching experiment methodology (Steffe & Thompson, 2000). Their activity addressing prompts related to the graph in Figure 4c was critical for allowing us to support and refine our models of each student's MV structure. Hence, methodologically, when exploring students' developing structures in situations involving multiple quantities, it is important for researchers to pay careful attention to the ways students may construct and coordinate quantities across a variety of prompts. Different prompts can provide different insights into students' MV structures (e.g., fixing different quantities and asking how the others change; asking to determine one quantity's value for fixed values of the other quantities). Further prompts can provide students with opportunities to refine or deepen their structures; we call for future research exploring this latter possibility.

Although we only present findings from a single context, we conjecture that most situations entailing multiple quantities allow students to construct different MV structures. Although this may create complications for teachers using such situations for instructional purposes (i.e., needing to carefully attend to each student's MV structures), we contend this is an affordance of such tasks. When making sense of such situations, students can engage in purposeful sense-making in ways accessible to them, just as LM and MJ were able to do. We also conjecture that such contexts may support students in connecting mathematical ideas in ways that deepen their understanding of these ideas individually (i.e., connecting covariation, percentages, linearity, etc.). We call for future research exploring the potential productivity of engaging students in situations entailing multiple quantities that can support MV reasoning. Such research could entail creating tasks that support students' MV reasoning as a powerful extension of their quantitative and covariational reasoning (Thompson & Carlson, 2017), thereby providing a stronger basis for their mathematical development.

EMOTIONS AS EXPLANATORY MECHANISMS IN MATHEMATICS LEARNING: A MULTILEVEL ANALYSIS OF AFFECTIVE-COGNITIVE CONFIGURATIONS

EMOCIONES COMO MECANISMOS EXPLICATIVOS EN EL APRENDIZAJE DE LAS MATEMÁTICAS: ANÁLISIS MULTINIVEL DE CONFIGURACIONES AFECTIVO-COGNITIVAS

Using data from 650 secondary school students from 20 mathematics classes in a rural region of Mexico, the study analyzes how emotional experiences are structurally linked to students' cognitive–attitudinal orientations and mathematics achievement, and differ within gender and teachers. A quantitative, cross-sectional design was employed, combining descriptive analyses, multiple regression models, and multilevel modeling. Enjoyment, boredom, and frustration are systematically associated with cognitive orientations toward mathematics, directly related to achievement. Significant variability in achievement was observed across teachers. Gender analyses revealed differentiated affective–cognitive configurations for female and male students. These findings position emotions not as background correlates, but as dynamic processes that organize cognition, shaping students' engagement and achievement in mathematics.

Keywords: Academic Emotions, Mathematics Achievement, Affective Domain, Teacher-Level Context

Purposes and Research Questions

The purpose of this study is to examine students' emotions as explanatory components within broader affective-cognitive configurations associated with mathematics performance. Although affective variables are frequently included in studies of mathematics achievement, they are often treated as correlates, background conditions, or secondary factors within predominantly cognitive explanations of learning. Consequently, while research has consistently documented associations between emotions and mathematics achievement, less is known about how emotional experiences become linked to students' beliefs, attitudes, and achievement outcomes. This gap is particularly relevant because affective processes do not operate in isolation but are intertwined with broader cognitive and social structures that shape students' engagement with mathematics (Goldin et al., 2011).

Specifically, the study aims to (a) characterize students' affective profiles in mathematics learning, (b) examine how emotions such as enjoyment, boredom, and frustration are associated with students' cognitive-attitudinal orientations and mathematics achievement, and (c) explore whether these affective-cognitive configurations vary across gender and teacher-level instructional contexts. Together, these analyses contribute to a model in which emotions are conceptualized as components of broader affective-cognitive systems embedded in students' mathematical activity and instructional contexts. Based on these aims, the study is guided by the following research questions:

1. What affective profiles characterize students' emotional experiences in mathematics learning?
2. How are students' emotional experiences structurally related to cognitive–attitudinal orientations and mathematics achievement?

3. To what extent do these affective–cognitive mechanisms vary across gender and teacher-level instructional contexts in mathematics classrooms?

Theoretical Framework

Emotions Within the Affective Domain in Mathematics Education

Within mathematics education, the affective domain has traditionally encompassed constructs such as emotions, attitudes, and beliefs (McLeod, 1989). Although these constructs are often discussed jointly, they are not theoretically equivalent. Early scholarship emphasized the importance of distinguishing them according to their temporal stability, scope, and relationship to mathematical activity. Emotions have been conceptualized as relatively short-lived, situation-dependent processes emerging during engagement with specific mathematical tasks, whereas attitudes and beliefs tend to reflect more stable and generalized orientations toward mathematics (McLeod, 1992).

This distinction is consequential for explanatory modeling. When emotions are treated as interchangeable with attitudes or beliefs, their dynamic and situational character is obscured, and they risk being reduced to background characteristics rather than active components of learning processes (Roth & Walshaw, 2019). By contrast, conceptualizing emotions as processes that unfold during mathematical activity foregrounds their potential to influence students' interpretations of tasks, engagement, and persistence in real time.

Contemporary psychological perspectives converge on this process-oriented view. Across theoretical traditions, emotions are understood as dynamic phenomena that emerge from interactions among individuals' appraisals, contextual demands, and prior experiences (Barrett, 2017; Moors, 2017; Pekrun, 2006). Rather than fixed traits, emotions are situated, context-sensitive processes that organize how individuals respond to learning environments. This processual understanding differentiates emotions from more stable affective constructs and underscores their relevance for models that seek to explain variation in academic engagement and performance.

Bringing these insights into mathematics education reinforces the need to treat emotions as analytically distinct components of the affective domain. If emotions arise in relation to specific classroom interactions and task demands, then their explanatory role cannot be adequately captured through correlational or background-variable approaches alone. Instead, they must be modeled explicitly within frameworks that account for how students experience and engage with mathematics in situated instructional contexts.

Emotions as Explanatory Mechanisms in Mathematics Learning

A growing body of research demonstrates that emotions play a substantive role in students' learning processes, particularly through their influence on engagement, regulation, and achievement-related behaviors (Camacho-Morles et al., 2021). Emotions shape how students allocate attention, interpret difficulty, and persist in challenging tasks, thereby influencing achievement not only indirectly but also through integrated cognitive–affective pathways (Pekrun et al., 2023).

Within the literature on academic emotions, enjoyment and boredom have been consistently associated with contrasting patterns of engagement. Enjoyment is linked to sustained effort, deeper processing, and adaptive regulation strategies, whereas boredom is associated with disengagement, avoidance, and diminished investment in learning activities (Pekrun & Linnenbrink-Garcia, 2014). These findings suggest that emotions operate not merely as concomitants of achievement but as processes that organize students' engagement with academic tasks.

Moreover, academic emotions are closely tied to students' appraisals of control, value, and task difficulty (Pekrun et al., 2023). Emotions can thus be understood as mediating processes that connect students' interpretations of instructional contexts with observable learning outcomes (Camacho-Morles et al., 2021). In this sense, emotional experiences are relational and embedded in classroom practices rather than detached internal states.

Research in mathematics education provides domain-specific evidence supporting this view (Hannula, 2012; Xolocotzin Eligio, 2017). Students' emotional experiences in mathematics are intertwined with how they interpret mathematical tasks, perceive difficulty, and position themselves within classroom norms. Emotions emerge in relation to particular forms of mathematical activity and instructional expectations, shaping students' opportunities for engagement and meaning making within the discipline.

Because emotional processes are situated within classroom interactions, they are not expected to operate uniformly across learners. Prior research has documented systematic differences in affective engagement related to gender and to instructional practices (Boaler, 2002; Forgasz & Leder, 2017). In some educational contexts, female students demonstrate higher classroom achievement than male students, yet this advantage is not consistently mirrored in standardized assessments (Gómez, 2025). Such discrepancies suggest that achievement outcomes may be organized through differentiated socio-affective configurations rather than through cognitive factors alone (Gómez, 2022).

From this perspective, emotions function as explanatory mechanisms that organize how students interpret instructional demands, regulate effort, and respond to evaluation contexts. Emotional experiences such as enjoyment, frustration, and boredom are expected to shape students' cognitive–attitudinal orientations toward mathematics and, through these configurations, influence achievement. These mechanisms are embedded within specific instructional environments and may be organized differently for female and male students.

Method

Research Design

This study employed a quantitative, cross-sectional research design to examine students' emotions as explanatory mechanisms in mathematics learning. Analyses were conducted using an integrated approach combining multiple regression analyses and multilevel modeling in order to examine explanatory relationships among affective, cognitive–attitudinal, and achievement variables, while accounting for the nested structure of the data (students nested within mathematics teachers). This design allows for the examination of emotional mechanisms at the student level, as well as for the assessment of teacher-level variability in students' mathematics achievement.

Participants and Context

Participants were secondary school students and mathematics teachers from public schools located in the municipality of Halachó, Yucatán, Mexico. This predominantly rural region is characterized by socioeconomic vulnerability and limited educational resources, providing a relevant backdrop for the study. Within this setting, teachers constitute the primary contextual level of analysis, as students' achievement and affective–cognitive configurations are examined in relation to the mathematics teacher to whom they are assigned.

The student sample consisted of approximately 650 students enrolled in Grades 1 to 3 of lower secondary education (ages 12–15), including both female and male students. Participants attended five public secondary schools: one general secondary school and four telesecundarias, a distance-based educational modality designed to serve rural communities.

The teacher sample included 20 mathematics teachers responsible for mathematics instruction in the participating classrooms. Teacher data were used to characterize classroom contexts and to inform the classroom-level structure of the multilevel analyses.

Measures and Data Collection

Students' emotional experiences in mathematics were assessed using the Inventory of Emotions Experienced by Adolescents when Solving Mathematical Tasks (INETAM), a self-report instrument developed and validated in Spanish for Mexican secondary school students (Gómez et al., 2020). INETAM measures achievement-related emotions experienced during mathematical activity, including enjoyment, boredom, enthusiasm, and frustration, and conceptualizes emotions as situational and task-related processes rather than stable affective dispositions. Responses ranged from 1 (not at all like me) to 4 (exactly like me), with higher scores indicating greater endorsement of the corresponding construct.

Additional student measures assessed students' satisfaction with mathematics classes, general mood states related to school experience, and perceptions, beliefs, and attitudes toward mathematics, including views about learning mathematics and personal engagement with the subject. These measures used the same four-point response format. Mathematics achievement was operationalized using students' course grades obtained from official school records.

Teachers completed a questionnaire assessing sociodemographic and professional characteristics, as well as affective experiences related to teaching mathematics. Teachers also reported perceptions of students' motivation, learning, and performance differentiated by gender. These data were used to characterize classroom contexts and to support the specification of classroom-level components in the multilevel models.

Analytic Strategy

Preliminary analyses included data screening, inspection of missingness and outliers, and evaluation of regression and multilevel assumptions. Correlational analyses were conducted to examine associations among cognitive, affective, and achievement variables and to guide model specification.

Analyses proceeded in three stages. First, descriptive statistics and gender comparisons were estimated for key cognitive and affective variables. Second, sequential multiple regression models were estimated at the student level to examine (a) cognitive predictors of mathematics achievement and (b) affective predictors associated with each cognitive node. Additional regression analyses were conducted controlling for student sex and school type to evaluate the robustness of the proposed model. Third, multilevel modeling was employed to account for the nested structure of the data (students within teachers). A null random-intercept model was estimated to compute the intraclass correlation coefficient (ICC), followed by models including student-level predictors to examine whether cognitive effects remained significant after accounting for classroom-level variability.

All analyses were conducted using IBM SPSS Statistics (Version 26), with statistical significance evaluated at conventional alpha levels.

Results

Descriptive Statistics of Key Study Variables

Descriptive statistics were computed for mathematics achievement, students' perceptions, and emotional variables included in the analytic models. Mathematics achievement, measured through students' average mathematics grades, showed a mean of 8.08 (SD = 1.45). An independent-samples t test indicated a statistically significant difference in mathematics achievement between female and male students, with girls obtaining higher mean scores than

boys, $t_{(635)} = 3.79$, $p < .001$. On average, students reported moderate levels of positive emotions related to mathematics learning, such as enthusiasm ($M = 2.28$, $SD = 0.71$), facilitation–enjoyment ($M = 2.37$, $SD = 0.73$), and effort–enjoyment ($M = 3.12$, $SD = 0.76$). Negative emotions associated with boredom and frustration were reported at moderate levels, including frustration ($M = 2.04$, $SD = 0.64$), disengagement–boredom ($M = 2.31$, $SD = 0.75$), and discomfort–boredom ($M = 1.88$, $SD = 0.75$). Students' perceptions of mathematics reflected moderate levels of perceived interest and self-efficacy.

Preliminary Correlations Among Key Study Variables

To examine the structural relationships among achievement, cognitive–attitudinal variables, and academic emotions, Pearson correlation analyses were conducted. The purpose of this preliminary step was to identify patterns of association and internal organization among constructs prior to advancing to regression and structural modeling analyses.

Table 1: Correlations Among Mathematics Achievement and Cognitive-Affective Variables

Variable	1	2	3	4	5	6	7	8	9
1. Mathematics Achievement	—								
2. Mathematics Is Easy	.353	—							
3. Defeatist Attitude	−.381	−.588	—						
4. Rejection Attitude	−.323	−.397	.593	—					
5. Deterministic Beliefs	−.327	−.483	.713	.708	—				
6. Boredom	−.329	−.434	.640	.642	.703	—			
7. Frustration	−.244	−.397	.605	.559	.595	.752	—		
8. Enthusiasm	.266	.411	−.478	−.513	−.475	−.496	−.354	—	
9. Enjoyment	.288	.481	−.522	−.516	−.508	−.540	−.435	.840	—

Note. Pearson's r coefficients are reported. Only correlations of moderate magnitude or higher ($r \geq .25$) are presented to emphasize substantively meaningful associations (Cohen, 1988; Schober et al., 2018). All reported correlations are statistically significant at $p < .001$. Sample size ranges from 637 to 655, depending on the variable pair.

The correlational matrix (Table 1) reveals a coherent structure linking mathematics achievement, cognitive beliefs, attitudes, and emotions. Achievement aligns positively with perceived ease of mathematics and positive emotions, and negatively with defeatist and rejection attitudes, deterministic beliefs, boredom, and frustration. Perceived ease follows the same directional pattern, showing consistent alignment with positive emotional experiences and inverse associations with negative beliefs and attitudes.

Defeatist attitude, rejection attitude, and deterministic beliefs form a tightly interconnected cluster and are strongly associated with boredom and frustration. Overall, the matrix displays two clearly differentiated configurations: one grouping achievement, perceived ease, and positive emotions; and another grouping negative attitudes, deterministic beliefs, and distress-related emotions. The pattern suggests substantial shared variance within each configuration.

The emotion-only matrix (Table 2) shows strong internal coherence within valence categories. Positive emotions (enthusiasm and enjoyment) cluster together, while negative emotions (frustration and boredom) also form a tightly associated grouping. Associations between positive and negative emotions are consistently inverse but weaker than the within-valence associations. This indicates that emotional experiences are organized into two internally

consistent clusters, with substantial but not complete opposition between positive and negative affective states.

Table 2: Correlations Among Mathematics Achievement Emotions

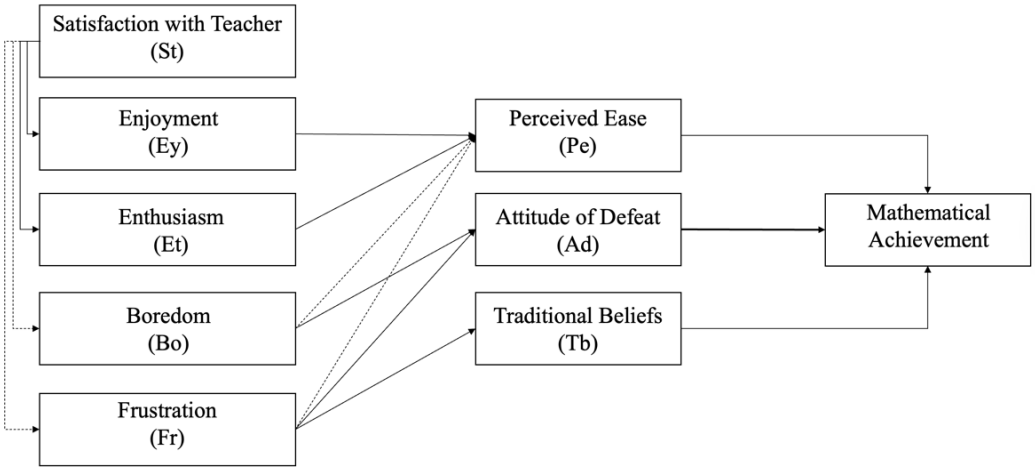
Variable	1	2	3	4
1. Frustration	—			
2. Enthusiasm	−.354	—		
3. Enjoyment	−.435	.840	—	
4. Boredom	.752	−.496	−.540	—

Note. Pearson's r coefficients are reported. All reported correlations are statistically significant at $p < .001$. Sample size ranges from 637 to 655, depending on the variable pair.

Teacher-Level Variation in Student Achievement

A null multilevel model with students nested within teachers was first estimated to examine the extent to which variability in mathematics achievement was attributable to differences between teachers. Results revealed significant between-teacher variability in students' mathematics achievement. The intraclass correlation coefficient (ICC) indicated that approximately 17% of the total variance in achievement was attributable to teacher level, with the remaining variance attributable to differences among students within classrooms.

To determine whether teacher-level variability persisted beyond students' individual characteristics, a random-intercept model including cognitive predictors of mathematics achievement (perceived ease, attitude of defeat, and traditional beliefs) and affective variables (satisfaction with teacher, mood states, and perceptions of mathematics) was estimated. The variance component for teacher level remained statistically significant, indicating that meaningful between-teacher differences persisted after controlling for student-level predictors.



These findings suggest that mathematics achievement is shaped not only by students' affective-cognitive profiles but also by the instructional contexts in which they learn. Although satisfaction with teacher was associated with students' affective experiences, exploratory analyses revealed significant differences among teachers in mathematics achievement, $F(20, 632) = 6.25$, $p < .001$, $\eta^2 = .165$, perceived ease, $F(20, 616) = 3.12$, $p < .001$, $\eta^2 = .092$, and traditional beliefs, $F(20, 626) = 2.16$, $p = .003$, $\eta^2 = .064$. These findings suggest that teacher-level variability extends beyond students' perceptions of teacher satisfaction and may reflect broader classroom-level affective-cognitive configurations.

Cognitive and Affective Predictors of Mathematics Achievement

To examine how students' cognitive–attitudinal orientations and affective experiences relate to mathematics performance, a series of sequential multiple regression models was estimated at the student level. Model specification was informed by correlational patterns and distinguished between direct cognitive predictors of achievement and affective predictors associated with each cognitive node.

In the cognitive model, mathematics achievement was regressed on perceived ease (Pe), attitude of defeat (Ad), and traditional beliefs (Tb). The model was statistically significant and explained 23% of the variance in achievement. Perceived ease ($b = .176$) and traditional beliefs ($b = .264$) were positively associated with achievement, whereas attitude of defeat showed a negative association ($b = −.376$) and emerged as the strongest direct predictor. Affective variables were then modeled as predictors of each cognitive node. Enjoyment and enthusiasm were positively associated with perceived ease, whereas boredom and frustration were linked to

lower perceived ease and stronger negative attitudes. Boredom and frustration showed robust positive associations with attitude of defeat, and frustration was also positively associated with traditional beliefs. Satisfaction with teacher was consistently related to students' affective experiences but showed only weak direct association with achievement once cognitive and affective variables were included, suggesting an indirect role through affective–cognitive positioning. The resulting structure is summarized in Figure 1.

Note. Solid arrows represent positive associations; dotted arrows represent negative associations. Cognitive–attitudinal variables (Perceived Ease, Attitude of Defeat, and Traditional Beliefs) were entered as direct predictors of mathematics achievement. Affective variables were modeled as predictors of the cognitive nodes. Satisfaction with teacher was associated indirectly with achievement through students' affective experiences. The figure represents the sequence of regression models tested and should not be interpreted as evidence of causal or strictly unidirectional relations among variables.

Figure 1: Cognitive–Affective Configurations Associated with Mathematics Achievement

Additional analyses indicated that the cognitive model remained stable after controlling for student sex and school type. Perceived ease (b = .152), defeatist attitude (b = −.382), and traditional beliefs (b = .213) continued to emerge as significant predictors of mathematics achievement. Student sex (b = −.170) and school type (b = −.175) were also significant predictors of achievement.

Gender Differences in Affective Experiences and Cognitive–Affective Configurations

Independent-samples t tests identified gender differences in a limited subset of variables. Female students reported higher frustration and higher effort–enjoyment, whereas male students reported greater perceived pleasantness of mathematics. Mathematics achievement also differed significantly, with girls (M = 8.31, SD = 1.42) outperforming boys (M = 7.88, SD = 1.46), $t_{(636)}$ = 3.79, p < .001. No statistically significant gender differences were observed for enthusiasm, boredom dimensions, perceived difficulty, usefulness, interest, or mathematics self-efficacy.

Regression analyses showed a shared cognitive structure across sexes, with attitude of defeat negatively predicting achievement in both groups. However, magnitudes and explained variance differed. For females (N = 297), the cognitive model explained 26.6% of variance (R^2 = .266), with attitude of defeat as the strongest predictor (b = −.396, p < .001), followed by beliefs of incapacity (b = .244, p < .001) and perceived ease (b = .208, p = .002). For males (N = 314), the model explained 22.9% of variance (R^2 = .229); attitude of defeat remained strongest (b= −.329,

$p < .001$), though weaker than among females, while perceived ease ($b = .151$, $p = .012$) and self-efficacy ($b = .140$, $p = .009$) were also significant.

Affective models showed differentiated salience. For females ($N = 310$), 13.8% of variance was explained ($R^2 = .138$), with boredom emerging as the strongest predictor ($b = -.321$, $p < .001$). For males ($N = 316$), the model explained 17.8% ($R^2 = .178$); enjoyment ($b = .209$, $p = .001$) and satisfaction ($b = .156$, p = .006) were positively associated with achievement, whereas boredom showed a smaller negative association ($b = -.173$, $p = .005$). Overall, cognitive predictors accounted for more variance in both groups, but negative attitudinal weight was stronger among females, whereas positive affect showed greater salience among males.

Discussion and Conclusions

The present study examined emotions as explanatory mechanisms in mathematics achievement by integrating cognitive, affective, and contextual levels of analysis. Consistent with process-oriented perspectives on academic emotions, the findings indicate that emotions are not peripheral correlates of learning but dynamic processes that shape students' engagement with mathematics within instructional contexts (Pekrun, 2006; Pekrun et al., 2023). Across models, affective variables such as enjoyment, boredom, and frustration were systematically associated with students' cognitive orientations toward mathematics—particularly perceptions of ease and attitudes of defeat—which in turn were directly associated with achievement outcomes. Rather than supporting a strictly unidirectional pathway from emotions to cognition, the findings suggest that emotional experiences, beliefs, and attitudes operate as interconnected components of broader affective–cognitive systems that contribute to mathematics achievement.

These results align with prior work in mathematics education emphasizing the central role of affect in students' mathematical activity (Hannula, 2012; Roth & Walshaw, 2019), while extending this research by demonstrating that emotional processes operate within classroom-level structures. The significant between-teacher variability observed in the multilevel models supports the interpretation of classrooms as distinct affective–cognitive environments rather than interchangeable instructional settings, reinforcing sociocultural and context-sensitive views of mathematics learning (Boaler, 2002).

Gender-related analyses further revealed differentiated affective pathways to achievement. Female students' performance appeared more strongly linked to the regulation of negative emotions and persistence under conditions of frustration, whereas male students' achievement was more closely associated with positive engagement and perceived ease. These differentiated configurations are consistent with prior research showing that gender differences in mathematics are better understood in terms of affective experiences and engagement patterns than in terms of ability differences (Forgasz & Leder, 2017).

From a PMENA perspective, this study advances research on affect in mathematics education by moving beyond variable-centered approaches and demonstrating how emotions operate as explanatory mechanisms embedded in classroom contexts. By integrating student-level affective–cognitive configurations with teacher-level variability, the study contributes to a more process-oriented understanding of mathematics learning.

The results underscore the importance of attending to emotional processes when seeking to understand equity in mathematics education. Recognizing that students may achieve through differentiated affective pathways highlights the need for instructional approaches that are sensitive to emotional diversity and contextual demands. From this perspective, addressing affective mechanisms may be critical for understanding discrepancies between school-based achievement and performance in standardized assessments, particularly in contexts where girls'

higher classroom achievement is not consistently mirrored in large-scale testing outcomes (Gómez, 2025; Gómez, 2022).

THE ROLE OF SELF-EFFICACY IN CALCULUS STUDENTS' ENROLLMENT AND ENGAGEMENT IN A MERIT PROGRAM

Melinda Lanius
Auburn University
melinda.lanius@auburn.edu

Jen Crooks Monastra
University of South Carolina
crooksj@mailbox.sc.edu

At large universities where calculus is taught in a large lecture with an accompanying recitation, a Merit recitation program can replace the typical recitation. Merit recitations meet for twice as long, have a smaller class size, and a specifically trained graduate teaching assistant who guides students through tough problems and understanding the core concepts. We consider the role of self-efficacy and how Bandura's sources of information influence Merit students' decisions to opt into an elective Merit recitation and influence their in-recitation learning experiences. Data consists of two end-of-semester focus groups with 12 Merit participants. Through the data analysis, we provide two personas, which embody the rich variety of goals and motivations amongst undergraduate calculus students. The findings and methods can help program directors conduct student-centered program refinement.

Keywords: Calculus; Identity and Agency; Affect, Emotion, Beliefs, and Attitudes; Undergraduate Education

The 2015 Mathematical Association of America's study of successful calculus programs in the United States (Bressoud, Mesa, & Rasmussen, 2015) found that the use of active-learning strategies as the primary mode of instruction, or as a complement to lecture, was one of seven key characteristics of success. Unfortunately, in a follow up study on which of these characteristics were being implemented by graduate-degree granting mathematics departments, Rasmussen et al. (2019) found that many mathematics departments are struggling to implement active learning despite valuing this approach to instruction. As is common at many large universities in the United States, Calculus 1 at our large R1 university is taught in a large lecture recitation format. This is a newer model for our institution; in Fall 2022 we shifted from a model of many small sections taught by graduate teaching assistants (GTAs) to large lectures taught by a faculty member with supporting recitations led by GTAs. Many of our GTAs, unfamiliar with this model, lectured in recitation (despite students attending a lecture on the same content the day prior).

To spark a broad shift towards the use of active learning techniques within calculus recitations, we initiated a Merit program for Calculus 1 adapted from the Merit Program for Emerging Scholars from the University of Illinois at Urbana-Champaign and the well-known Treisman (1992) Mathematics Workshop Program (University of California Berkeley). This type of program has been implemented under a variety of names (e.g. MathExcel) at various points in time across the United States, including at Northwestern University, Northeastern University, University of Wisconsin Madison, University of Kentucky, Wayne State University, San Francisco State University, Oregon State University, and Cerritos College (University of Illinois, n.d.). The version at the University of Texas at Austin, called the Emerging Scholars Program, was shown to increase participants' odds of earning a calculus grade of an A or B and increased their preparation for Calculus 2 (Moreno et al., 1999).

Our research project emanates from a design problem: After building this alternative calculus recitation modeled after Merit, one designed to provide extra support in Calculus 1, we did not achieve full enrollment capacity (reaching ~76%). The program director wanted to understand

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

who the program was serving and what influenced their choice to enroll. Our research objective was to understand the incoming mathematical self-efficacy of program participants and how this influenced enrollment and in-program learning experiences. From this research, we supported the redesign of the program by building personas of program participants. Coming from the field of user design of digital technologies, personas are "life-like archetypes that stress users' diverse goals and motivations and embrace their corresponding needs and challenges" (Huynh et al., 2020) that are derived from the results of certain types of qualitative research. Rather than bypassing our design problem and solely focusing on the resulting research, we foreground our paper within a design process because we believe this user-centered approach to solving complex programmatic challenges will be of broader interest to the North American chapter of the International Group for the Psychology of Mathematics Education (PME-NA) community. In this paper, we share the findings of our research study and the resulting personas.

Context

A Merit recitation replaces the typical recitation and is twice as long to allow more time for the implementation of active-learning strategies, primarily group work. Merit recitations also have fewer students than standard recitations and are facilitated by a specifically trained GTA to guide students through solving problems. A central component of this change effort was the introduction of an 8-session Merit GTA professional development workshop series, which in 2024 and 2025 was attended by 9 and 11 GTAs respectively. Two GTAs were selected from each training cohort to lead a Merit recitation section the following fall; the other GTAs taught standard-type recitations where they still had the opportunity to put into practice the active learning strategies from the training, however with less in-class time than was available to their Merit GTA peers. In Summer 2024 and 2025, every student enrolled in Calculus 1 (700–900 students) was invited by email to switch from their standard-type recitation into a Merit recitation section. The email subject called this an "opportunity" with the body saying:

> You are eligible for a special section of Calculus 1, called Merit recitation! These recitation sections: have much smaller class size and a more personalized learning experience with a highly trained facilitator, and provide extra time to tackle tough problems and prepare for exams. (Earn one extra credit hour). We will fill these sections in the order I receive emails, so if you would like a slot, please email me at [email] as soon as possible!

In Fall 2024, 16 and 10 students opted into a Merit recitation section respectively. In Fall 2025, 10 and 17 students enrolled in a Merit recitation section. Time of day, either an 8 am start or a 5 pm end, partially accounts for the uneven distribution of students between the two Merit sections. In this report, we focused on the Fall 2024 Merit student cohort.

Relevant Theory & Research Question

We conceptualize mathematical self-efficacy broadly as a student's belief in their own capacity to learn and be successful—as they define it—in calculus. Mathematical self-efficacy has been shown to predict students' problem solving performance and to mediate effects of gender and prior experience on academic performance (Pajares & Miller, 1994). Psychologist Albert Bandura (1978) provided the foundation of our modern understanding of self-efficacy, positing the existence of four "sources of information" that strengthen or hinder self-efficacy: performance accomplishments, vicarious experiences, verbal persuasion, and emotional arousal. Performance accomplishments encapsulate prior success, or mastery, experiences which can increase overall self-efficacy and experiences of failure, which can negatively impact self-

efficacy. In mathematics, an experience of "getting a good grade" on an exam operates as a performance accomplishment. Vicarious experiences come from social comparison to peers and relate to witnessing or listening to the experiences of others. In our setting, a student seeing their peers struggling with a homework assignment and concluding that they will also struggle would constitute a vicarious experience operating as a source of information influencing self-efficacy. Verbal persuasion concerns the implicit or explicit external messages relayed from peers, instructors, advisors, or parents and can be both positive and negative. A recitation leader saying "I believe you can do well on this exam" could be verbal persuasion. In our study, emotional arousal concerns students' self-assessment of their anxiety or stress level. For example, a student who knows they are prone to high levels of test anxiety is more likely to have low self-efficacy with respect to completing exams.

Many researchers have explored connections between self-efficacy and various mathematical outcomes. For instance, Hammad et al. (2022) studied the relationship between self-efficacy, motivation, and achievement (grades) among undergraduates placing into foundational mathematics. Implementing a program similar to Merit, they found students self-efficacy improved throughout the semester and established a positive correlation between self-efficacy and achievement. Further, students (n = 130) described the teaching methods, group work, teacher attitude, and gamification as significant factors for increasing their self-efficacy. A study by Zientek et al. (2019) examined self-efficacy scores among students enrolling in developmental mathematics courses designed to incorporate active learning pedagogy and just-in-time supports at multiple U.S. universities. They found overall positive changes in self-efficacy and noted that sources of self-efficacy differed based on students' course grades. Further, mastery experiences and social persuasion saw the greatest gains, as was expected since group work and collaborative learning were emphasized in the course. They also reported a decrease in emotional arousal, suggesting students experienced less math anxiety. Thus, as self-efficacy influences the effort and persistence a person puts into a task (Bandura, 1978), it has been a useful construct to investigate in the context of mathematical learning.

Clemente et al. (2024) conducted a literature review on interventions designed to enhance students' mathematics self-efficacy. Findings grouped interventions into four types: (1) mastery-based, (2) peer modeling and collaboration, (3) teacher support and feedback, and (4) technology-based. Although the effectiveness of technology-based interventions was mixed, all other interventions showed consistent effectiveness for fostering positive beliefs and influencing student engagement, motivation, and mathematical achievement. Zakariya (2022) also reviewed and described sources of information in effective intervention studies designed to promote mathematical self-efficacy. Additionally, students themselves can provide insight into how and why these sources of information change their self-efficacy (White, 2025). We consider the following research question: In what ways do sources of information influence Merit students' decisions to opt into a Merit recitation and influence their in-recitation learning experiences?

Methods

A total of 12 students participated in two focus groups, of size eight and four respectively, conducted during the last week of class in Fall 2024. The gender ratios of the focus groups were skewed (this was not purposeful on our part) with the first group being primarily women (with one man) and the second being all men. The focus group protocol explored their decision-making process for enrolling in Merit in Summer 2024, overall Merit program experiences, and suggestions for improving the course. For example, under recruitment, students were asked

"What about the Merit program might have seemed appealing to you?" and "Why did you decide to sign up?"

Both focus groups were audio-recorded, transcribed by AI, cleaned by a member of our team, and coded by both authors. The data analysis involved two levels of coding. We began with an a priori approach to coding (Saldaña, 2016), independently analyzing the transcripts for examples of Bandura's four sources of information (performance accomplishments, vicarious experiences, verbal persuasion, and emotional arousal), as well as indications of the overall state of their mathematical self-efficacy (high or low). After coding less than half of the first focus group, we met to compare codes. A research log (Maxwell, 2013) documented discussions of differences in coding, resulting in a stronger codebook with examples and agreed upon definition of terms. For instance, we agreed that "vicarious experiences" included imagining scenarios or experiences such as what happens in other recitations or making predictions about student experiences in a general context (i.e. no one would pass a test learning in lecture alone). Thus, the first cycle of coding informed our research log of examples and improved our codebook for sources of information in context of calculus recitations.

We began a second cycle of coding by independently coding the entire first focus group for the four sources of information and overall assessment of self-efficacy. We met weekly to discuss codes to reach consensus. A second level of coding was added to explore the content of the passages. For example, codes for "verbal persuasion" included the source of the persuasion (email, parents, GTA, etc.) while "emotional arousal" identified the feeling or emotion expressed (humbling, fear, feeling unprepared, etc.). Second level coding included verses codes (Saldaña, 2016) as our data often included comparisons either between Merit and lecture or between Merit recitations and other recitations, and in-vivo codes (Saldaña, 2016) to maintain the students' perspective in the analysis. This process continued with focus group two. Once the coding was completed, passages containing the same codes were collapsed into code stacks. Code mapping, collapsing codes into common categories, was used for each source of information (Saldaña, 2016), with each author analyzing one focus group. For example, categories of level two codes under "performance accomplishments" included "Merit class norms," "Merit verses lecture," and "background." Memos summarizing the code mapping were drafted and reviewed by both authors, forming the basis for the development of each persona. Thus, the personas illustrate how Bandura's sources of information can interact to shape the learning experiences of students.

Findings

We will first present the overall findings and then disaggregate by focus group to present the personas. Sources of information are presented in the order of frequency and/or strength of influence, with the most frequent/strongest findings first.

Decision to Enroll in Merit

Students described all four sources of information as they discussed the appeal of the Merit recitations and what they hoped to gain from enrolling.

Verbal persuasion. The recruitment email served as the main source of verbal persuasion that encouraged students to sign up for Merit, although parents were also mentioned as a factor for some students. Students frequently pointed to the smaller class size mentioned in the email as a key appeal of the Merit recitations. For instance, one student stated: "I saw less people and I said join," and another explained "the main thing was not as many people." Others appreciated having more class time, working with a specially trained TA, being able to receive one-on-one help, and the opportunity to earn an extra credit hour. A few found the title of "Merit" special and thought the "experimental" section would be good for their resume or suggested it sounded

like an honor to enroll. In one focus group, several students mentioned parents affirming the need for Merit by suggesting their students would feel lost in a big class or needed the extra help.

Vicarious experiences. While discussing why they opted to enroll in a Merit recitation section, some students repeatedly alleged that Calculus 2 at this institution was notoriously difficult according to other students and identified this as their reason for enrolling in Merit. Many of these students explained that even though they had taken Calculus 1 in high school, they had been told by other students that "Calculus 2 is apparently really hard, so I wanted to redo it [Calculus 1]." Students also imagined they could "actually get help" in Merit based on the smaller class size, ensuring they would "know what I am doing."

Emotional arousal. Emotions were another source of information which influenced many students' decision to enroll. Students described feelings such as stress, fear (e.g. one student shared "I was just afraid" to take calculus), and nervousness about grades. Additionally, even students with high school calculus experience felt they had gaps in their knowledge or expressed a fear of enrolling in Calculus 2. In one focus group, students repeatedly emphasized their stress around being prepared for Calculus 2 with one student saying, "I kind of said earlier about the Calculus 2, just like I really wanted to, I wanted to get Calculus 1 *down*, like good, before I got to that." Accordingly, emotion helped motivate these students to elect for the extra support offered by a Merit recitation.

Performance accomplishments/entering self-efficacy. Although both focus groups included students who had taken calculus in high school (both AP Calculus and non-AP were reported and some had AP credit), one focus group also included students with no prior calculus experience. Further, the groups described differing entering levels of self-efficacy for university level mathematics. Some students explained they were typically comfortable engaging in mathematics yet did not feel prepared for Calculus 2. Others expressed low self-efficacy, stating they were behind in math or needed "all the help I can get." Examples of low mathematical self-efficacy included statements such as I am "not very good at math," or "math is not my strong suit," or I know I am "bad at math."

Experiences of Merit

Evidence of all four sources were also evident as students described their experiences in Merit and the calculus lecture.

Performance accomplishments/overall self-efficacy. Students reported that the Merit recitations helped them understand the material, built their confidence, and provided a smooth transition from high school into university mathematics. Students frequently contrasted their experiences in Merit recitation with their experiences in the large lecture and declared "you definitely learn a lot more in recitation than you did in the lecture." Students also reported "you can't ask a question" in lecture and admitted it was difficult to focus in the large lecture hall. In contrast, students described Merit recitations as "fun" and "helpful" and joked they "have no choice but to pay attention" in Merit due to the small class size and active learning design. Students reported being consistently engaged in doing mathematics during recitation and found it a safe place to ask "stupid questions." Additionally, some students formed friendships through Merit and "grew a relationship" with their GTA.

Verbal persuasion. Many students mentioned their GTA, who expressed a belief that they could learn and understand calculus, as a positive influential source of verbal persuasion throughout the semester. According to the students, GTAs offered encouragement and helpful test taking advice. One student explained "seriously, sometimes before an exam I've been like, I'm going to fail and then [GTA] has changed my mind." Further, the GTAs broke down the

material, explained content well, engaged with all students, and guaranteed groups worked together during recitation.

Vicarious experiences. Many students attended another recitation for one class when a GTA was ill and described "night and day" differences between a normal recitation and their experience in Merit. Students perceived their peers "were not learning anything" in other recitations and observed that many were on their phones. Students also spoke about common challenges all students encounter with passing calculus, noting many have to change majors due to not passing calculus.

Emotional arousal. Students overwhelmingly described positive emotions when reflecting on their experiences with Merit recitations. Many felt cared for and supported, enjoyed the fun learning environment, and were "comfortable" asking for help. Some explained how the class environment made them feel "comfortable" and able to learn. One student explained how they got to know their peers "kind of like high school in a way. That's one of the good things, you start to get actually comfortable, and it makes it a little easier to learn when you're more comfortable with the people around you." Some recalled moments that were humbling due to reviewing prerequisite material yet noted "it needed to happen" or felt embarrassed not knowing something yet were willing to receive help from peers.

Personas

The sources of information underlying students' self-efficacy for university-level calculus described above form the content of our personas. Coming from the field of user-centered design in the context of computer technology development, personas are composite characters collated from research findings that personify specific trends and patterns in the data (Dam & Teo, 2025). In our case, personas will stress students' diverse motivations behind choosing to enroll in Merit to increase their chances of success in calculus and the ways that they filter sources of information. Personas create memorable users to design for and convey information in ways that other artifacts, such as results displayed in a chart, cannot (Adlin & Pruitt, 2010, p. 1). Personas have already been used productively in a few limited cases by STEM education researchers; e.g. in understanding the unique needs of undergraduate researchers in a physics department (Huynh et al., 2020) or secondary mathematics students in Austria (Weinhandl et al., 2024). In industry contexts, one may encounter personas that are fictional or "ad hoc," that is generated from the assumptions of the design team based on their past experiences interacting with users. However, Adlin & Pruitt (2010, p. 22) argue for a much more rigorous process that creates data-driven (and more effective) personas, which we will outline with respect to our process: (1) identify ad hoc personas that allow us to articulate our pre-existing assumptions and biases, (2) analyze the data (as done above), (3) generate skeletons by creating brief bulleted lists of distinguishing data points from findings, (4) advance skeletons into fully fledged personas by adding concrete data to individualize and convey personality, (5) validate your personas against your Step 2 findings. This process aligns with our methods as described above.

After completing our analysis, we discovered that the focus groups provided sufficient distinguishing characteristics for the generation of a skeleton for each group. Accordingly, we constructed two personas: Maddie captures the motivations and mathematical self-efficacy of students in Focus Group 1 (an 88% female group) and Jacob is a composite of the male participants in the second focus group.

Note that these two personas were disseminated as a poster at the 28th Annual Conference on Research in Undergraduate Mathematics Education (Crooks Monastra & Lanius, 2026).

In the skeleton phase, we identified the following salient differences: (1) incoming self-efficacy, (2) the role of parents in deciding to enroll, (3) how the classroom environment supports asking questions, (4) nature of relationships in recitation, and (5) the role of calculus in degree attainment.

Maddie. Maddie has low mathematical self-efficacy and enrolled in Merit because she "just wants to pass calculus." When Maddie shared information about the Merit program with her parents, they strongly encouraged her to enroll, conveying that she needs additional support especially because of the large lecture setting. During the semester, Maddie valued Merit recitations not only for the time and space to ask her questions but also for creating a safe feeling space to ask "humbling" questions, particularly about material she felt she was "supposed to know." Accordingly, Maddie's relationship with the Merit GTA was more salient than her relationship to her classmates. This GTA-student relationship served as the foundation for a safe place to ask questions. Maddie imagines she would have failed Calculus 1 without a Merit recitation.

Jacob. Jacob has at least modest mathematical self-efficacy in general but had low self-efficacy with respect to passing the next course in the math sequence: Calculus 2 at our institution. He has heard a lot of stories about how our Calculus 2 is "apparently really hard." When Jacob shared information about the Merit program with his parents, they were neutral, telling him to decide for himself if he wanted to take Merit. During the semester, Jacob valued Merit because it gave time and space for asking questions, especially in contrast to large lecture and regular recitation. Whereas Jacob valued his relationship with his Merit GTA, the relationships he developed with other students in the class were particularly important to Jacob. He valued having made friends during Merit and studying with these peers outside of Merit class time. Jacob reports leaving Merit feeling prepared for Calculus 2 in the spring.

Leveraging personas to redesign. These personas guide structural adjustments that better support the wide variety of students who choose a Merit recitation. In this example, the Merit director better understood the role of parents in summer enrollment and can better market the program. Additionally, knowing what motivated those who enrolled and what their concerns were, we can be more purposeful in what we highlight in marketing materials. Finally, to better support students like Maddie, who need to feel comfortable in order to ask questions during recitation, the director can stress particular aspects of the Merit GTA training. Accordingly, the persona approach to user-centered design may be a useful tool for other providers of elective student supports in the mathematical sciences.

Discussion

We wish to note that the gender of the personas directly reflects the composition of the focus groups. We are mindful of balancing accurate reflection of the data and also not wishing to reinforce harmful stereotypes with a particular presentation of self-efficacy in relation to gender. We have chosen this gendered presentation so as to not erase the voices of these female students and to convey their unique needs. Sanabria & Penner (2017) found a gendered difference in students' responses to failing calculus, and that women in particular were substantially less likely to earn a STEM degree after failing this course. On average, women may encounter unique challenges and could be internalizing sources of information differently than the average male peers in recitation. This internalization process may impact their mathematical self-efficacy to a greater extent than their male peers.

In terms of sources of self-efficacy, mastery experiences are often considered the strongest influence on an individual's overall efficacy (Zientek et al., 2019). However, in our study, we

found vicarious experiences and verbal persuasion to be more influential on students' decision to enroll in an elective recitation. This may not be surprising, given they were entering a new learning environment (i.e. transiting from high school to university) and thus relied more heavily on others' experiences. Further, our findings of parental involvement in students' enrollment decision-making may also be contextualized in the broader literature. We note that due to the privacy rights given to students at age 18 in the Family Educational Rights and Privacy Act of 1974 (FERPA), math educators at the tertiary level may not think of parents as active participants in a students' learning of mathematics. However, as we saw here and is the case nationally, parents can play an important and highly influential role in a students' transition from high school to college (Smith et al., 2018) and may influence students course enrollment decisions.

With respect to students' perceptions of active learning, Deslauriers et al. (2019) found that students learn more with an active teaching method but feel like they learn more in a passive lecture. This is inconsistent with our findings, which is likely due to the massive disparity in classroom size. In their review of the literature, Wright et al. (2019) concluded that research consistently indicates students perceive learning more as class size decreases. This suggests future work on the role of class size in students' perceptions of learning with respect to pedagogical style.

Conclusion

In the national landscape, calculus is a common target for programming that can range from mandatory (standard recitation) to an elective enrollment (e.g. Merit recitation), and supplemental programs (tutoring, supplemental instruction, final exam bootcamps). Understanding why students choose to engage in these activities can help the field more broadly understand how to support students in calculus. Although personas are highly context driven and our exact findings will not represent the broad range of student motivations and experiences, our process for developing personas may be empowering for other departments aiming to redesign calculus supports. Additionally, although there is a large body of research investigating the outcomes of participation in optional academic programs like supplemental instruction, this research typically does not account for student "self-selection," i.e. who decides to participate and why (Bowman et al., 2021). Thus, our findings, although context dependent, do contribute some understanding to this gap in the research.

Limitations

We focused solely on the decision process of students that did enroll in the program. To more fully capture the nuance of this design challenge, future research should target students that were invited and chose not to enroll. Further, our study only includes end-of-semester student data. Future research could follow students longitudinally throughout their semester, which would provide a more complete understanding of student efficacy and how it changes over time.

We hope that this study may serve as an inspiring case for others looking to engage in student-centered redesign of their calculus offerings.

COMPARING OPERATIONALIZATIONS OF CONCEPTUAL INSTRUCTION TO PREDICT STUDENT MATHEMATICAL SELF-BELIEFS

This analysis examines four different operationalizations of conceptual instruction (CI) in mathematics education, derived from previous research. Using data from the High School Longitudinal Study of 2009 (HSLS:09), confirmatory factor analyses (CFAs) and ordinary least squares (OLS) regression models are used to assess the psychometric properties and investigate the predictive relationship between conceptual instruction in mathematics and student self-concept and self-efficacy. Results demonstrate that operationalizations of conceptual instruction are robust to slight variations but suggest that conceptual instruction relies heavily on mathematical reasoning, problem solving, and connecting mathematical ideas. Conceptual instruction functions as a significant predictor of students' self-beliefs in mathematics.

Keywords: Measurement, Beliefs, Mathematical Thinking

As research in mathematics education tries to understand and overcome the challenges students face in learning mathematics, recent studies have focused on improving classroom instruction. The National Council of Teachers of Mathematics (NCTM) identified one problem with instruction in the US as "too much focus is on learning procedures without any connection to meaning, understanding, or the applications that require these procedures" (NCTM, 2014, p. 3), and advocates for high-quality instruction for all students. Fauzan (2013) states that high-quality mathematics instruction should include problem-solving, reasoning, communicating, connecting, and representing mathematics, and should have students engaged in critical and creative thinking. This type of instruction, frequently called conceptual instruction, contrasts with procedural instruction which focuses on memorization and proficiency in using algorithms to solve computational problems in mathematics. Though some research suggests both types of instruction are important (Nahdi & Jatisunda, 2020), other research found that spending extra time on conceptual instruction improved student understanding more than if that extra time was used on procedural practice (Rittle-Johnson et al., 2016).

Despite the recognized need for conceptual instruction, there is much variation in how it is described and operationalized. As a result, it is difficult to know exactly what educational practices most significantly contribute to conceptual instruction. This lack of clarity makes it difficult for experienced teachers to know how to improve their practice and for new teachers to receive the appropriate training that will enable them to provide conceptual instruction for their students. Additionally, though a link between students' conceptual knowledge and mathematics performance has repeatedly been observed, little research has investigated a connection between conceptual instruction and students' self-beliefs related to mathematics. Since increasing student confidence and interest in pursuing STEM fields is a current goal of mathematics education, it is important to know if conceptual instruction can improve those outcomes. Therefore, this analysis seeks to answer the following two questions: (1) How can conceptual instruction in mathematics be operationalized/measured? (2) Is there a relationship between conceptual instruction in mathematics and students' self-beliefs, specifically self-concept and self-efficacy?

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Literature Review

Though the need for high-quality mathematics instruction is universally agreed upon, research with this focus incorporates multiple educational theories and instructional activities. Some of the theoretical frameworks cited when working to increase students' conceptual understanding include Freudenthal's (1983) Realistic Mathematics Education (RME, See Sahin & Gurbuz, 2022), Taba's (1963) Concept Based Instruction (CBI, See Ncube & Luneta, 2025) and Ben-hur's (2006) Concept-Rich Instruction (CRI, See Tashtoush et al., 2022). Each framework takes a constructivist approach, positioning students as active learners who build deep understanding through applying mathematical principles in a variety of authentic contexts, and connecting procedures to principles. Most research on the topic studies the implementation of an instructional intervention or teaching activity that is meant to increase students' conceptual understanding and then measures its influence on learning outcomes. These studies can provide insights into how to improve conceptual instruction, but they do not measure conceptual instruction as a variable. Without a way to clearly operationalize and measure conceptual instruction in a classroom, future research is limited in its ability to examine how variation in the amount or quality of conceptual instruction relates to student outcomes.

Statistical Operationalization of Conceptual Instruction

A recent body of research has begun to address this concern by using data from the High School Longitudinal Study of 2009 (HSLS:09, Ingels et al., 2011, 2014) to statistically operationalize and measure conceptual instruction. The HSLS:09 is a nationally representative study designed to track students' trajectories from the beginning of high school through postsecondary education. In the baseline year it included a supplemental teacher survey asking ninth-grade mathematics teachers to report how much emphasis they placed on various instructional objectives. These items have been used by multiple research teams to construct measures of conceptual instruction, though their operationalizations differ in important ways.

McQuillen (2016) conducted a confirmatory factor analysis on the HSLS:09 teacher survey items and identified a conceptual instruction factor which included six items describing emphases on teaching mathematical concepts, developing problem-solving skills, reasoning mathematically, connecting mathematics ideas, teaching the logical structure of mathematics, and explaining ideas effectively. This same combination was theoretically proposed and statistically verified by Miles (2024) as well. Yu and Singh (2018) used the HSLS:09 data and included the six items that McQuillen and Miles models used but added three additional items that emphasize increasing student interest in mathematics, preparing students for further study in mathematics, and teaching about the history and nature of mathematics. Ji (2020) also had a six-item factor for conceptual instruction, but his was unique as he included an emphasis on preparing students for further study in mathematics and excluded the emphasis on having students explain ideas in mathematics. Finally, Gerasimova et al. (2023) operationalized conceptual instruction with a six-item factor, but their factor differed from the McQuillen and Miles models in significant ways. First, they excluded emphases on teaching mathematical concepts and reasoning mathematically, citing measurement issues. Secondly, they included the emphasis on increasing student interest in mathematics and were the only research team to include an emphasis on teaching students how to apply mathematics in business and industry. Other researchers argued that the emphases of preparing students for further study in mathematics or for business and industry applications could be enacted using either conceptual or procedural approaches, so they should not be included in a conceptual instruction variable (Miles, 2024).

Taken together, these HSLS:09 studies suggest that it is possible to statistically operationalize conceptual instruction using teacher survey data. However, the variation in item selection highlights the lack of consensus on which specific instructional emphases indicate conceptual instruction. This underscores the need for continued study and refinement of the different operationalizations and instruments designed to capture conceptual instruction.

Self-Beliefs in Mathematics: Self-Efficacy and Self-Concept

Most research on conceptual instruction has focused on student achievement as the dependent variable. However, achievement is not the only important outcome of mathematics instruction. Students' self-beliefs—particularly self-efficacy and self-concept—are among the strongest non-cognitive predictors of academic performance (Lee & Stankov, 2018; Stankov & Lee, 2017), and they influence a range of educationally significant outcomes including persistence, course selection, and career aspirations (Bandura, 1997; Eccles, 2009). Understanding whether instructional approaches can shape these beliefs is therefore consequential for both theory and practice.

Self-efficacy is part of Social Cognitive Theory (SCT) and refers to an individual's belief in their capacity to successfully carry out specific tasks (Bandura, 1986, 1997; Britner & Pajares, 2006). It is primarily developed through mastery experiences, vicarious experiences, social persuasion, and physiological states. It describes a student's belief that they can be successful at specific tasks in the future, like doing well on a mathematics test or mastering difficult material. Self-efficacy influences behavioral choices, effort, and persistence in the face of obstacles and is positively related to performance and persistence in mathematics (Bandura, 1986; Multon et al., 1991, as cited in Yu & Singh, 2018).

Self-concept, by contrast, is a broader, domain-specific evaluation of one's abilities that is past-oriented rather than future-oriented (Bong & Skaalvik, 2003; Marsh & Craven, 2006). Whereas self-efficacy asks, "Can I do this math task?" self-concept addresses the more general question, "Am I a math person?" The formation of self-concept relies on relative comparisons of one's own performance in mathematics to their performance in other domains, as well as comparison to their peers' performance in mathematics (Arens et al., 2022; Wolff et al., 2018). Self-concept evaluations also often incorporate students' attitudes related to mathematics while self-efficacy does not (Bong & Skaalvik, 2003).

Although self-efficacy and self-concept are related, they are empirically distinguishable constructs that are operationalized differently and predict different outcomes (Parker et al., 2014; Miles, 2025). Mathematics self-concept is more strongly related to school grades, whereas mathematics self-efficacy is more strongly related to standardized test scores (Arens et al., 2022). Both constructs display a reciprocal relationship with mathematics achievement where positive self-beliefs enhance future achievement, which in turn strengthens self-beliefs (Marsh & Craven, 2006). In large-scale international assessments, self-efficacy and self-concept consistently emerge among the strongest non-cognitive predictors of mathematics achievement, showing stronger effects than socioeconomic status (Lee & Stankov, 2018; Stankov & Lee, 2017). These findings position self-beliefs as promising targets for educational intervention.

Connecting Conceptual Instruction to Self-Beliefs

There are strong theoretical reasons to expect conceptual instruction to positively influence students' self-beliefs. According to SCT, mastery experience is the most powerful contributor to self-efficacy (Bandura, 1997), and conceptual instruction may provide more meaningful mastery experiences, leading students to view their success as genuine and transferable. Yu and Singh (2018) hypothesized such a relationship but noted that few studies had directly examined links

between conceptual instruction and student motivation or beliefs. Ncube and Luneta (2025) likewise suggest that students who receive conceptual instruction may show increased confidence and come to view mathematics as "doable, accessible and enjoyable."

From a self-concept perspective (Eccles & Wigfield, 2002; Tracey et al., 2020), conceptual instruction may strengthen self-beliefs and attitudes by helping students connect ideas and apply mathematics in personally meaningful contexts. As students develop deeper understanding and see mathematics as relevant and meaningful for themselves, their mathematics self-concept may improve. Despite these theoretical rationales, most studies focus on achievement outcomes so direct empirical evidence linking conceptual instruction to self-beliefs remains limited.

In summary, the existing literature suggests that conceptual instruction can be operationalized and measured; however, uncertainty remains regarding the most appropriate operationalization. Additionally, though a large body of literature suggests that conceptual instruction positively predicts student achievement, there are fewer studies that examine its influence on students' self-beliefs. Further investigation into the relationship requires both refined measurement of conceptual instruction and direct empirical investigation of its relationship to students' self-efficacy and self-concept. Such research would advance understanding of the full range of benefits that conceptual instruction may confer and help educators design instruction that not only improves performance but also strengthens the mathematical self-beliefs that sustain long-term mathematical engagement.

Methods

To statistically evaluate alternative operationalizations for conceptual instruction and identify any relationship that exists between conceptual instruction in mathematics and students' mathematics self-efficacy and self-concept, I conducted an analysis of the publicly available HSLS:09 data (Ingels et al., 2011, 2014). The specific data for this study came from the baseline year and first follow up surveys. In the baseline year study, parents and mathematics teachers of all participants were asked to complete surveys to provide additional context. Both the student and teacher surveys are used in this study, and all analyses were run in Rstudio (version 4.3.1) using the lavaan (Yves, 2012) package.

The Variables

The following variables were included in the analysis:

1. Conceptual Instruction (CI) – Four versions of this variable align with the four different HSLS operationalizations outlined previously. The items for each variable came from the teacher instrument in the baseline year of data collection where teachers rated the amount of emphasis (on a 4-point scale) they placed on different elements of mathematics instruction. Individual factor scores were extracted from CFA models to use as measures of conceptual instruction in the regression analysis.
2. Mathematics self-efficacy (x1mtheff, x2mtheff) – the HSLS:09 team created composite variables using principal components analysis to measure student self-efficacy. The variables are comprised of four items asking students to rate how confident they are at understanding their textbook, mastering skills, and doing well on exams and assignments. Variable weights correct for missing data, and each variable is standardized with a mean of 0 and standard deviation of 1.
3. Mathematics self-concept (x1mthid, x2mthid) – the HSLS:09 team created these variables from two items at each timepoint that asked students to rate how strongly they (and others) considered themselves a "math person." Again, variable weights correct for

missing data, and each variable is standardized with a mean of 0 and standard deviation of 1.

4. Control variables: Student sex (dummy variable coded 0 for male and 1 for female), student race (dummy variable coded 1 for White/Asian and 0 for other non-white), and students' socioeconomic status (continuous HSLS:09 created variable that measures SES in relation to locale and parent occupation and educational level).

Procedure

To compare different operationalizations of conceptual instruction, I created one-factor confirmatory factor analysis (CFA) models that aligned with each of the models cited previously in this paper. I ran all models using robust standard errors and a WLSMV estimator to correct for non-normal Likert-type data. I compared the models using the *Comparative Fit Index* (CFI), the *Tucker-Lewis Index* (TLI), the *Root Mean Square Error of Approximation* (RMSEA), and the *Standardized Root Mean Square Residual* (SRMR). Table 1 compares the fit for each of the conceptual instruction variables.

Table 1: Fit Indices for Confirmatory Factor Analysis Models of Conceptual Instruction

Model	Items	CFI	TLI	RMSEA	SRMR
Yu & Singh (2018)	9	.990	.987	.041	.041
McQuillen (2016) / Miles (2024)	6	.995	.992	.042	.033
Ji (2020)	6	.992	.987	.053	.046
Gerasimova et al. (2023)	6	.992	.987	.037	.029

Note. CFI = Comparative Fit Index; TLI = Tucker-Lewis Index; RMSEA = Root Mean Square Error of Approximation; SRMR = Standardized Root Mean Square Residual. All models used robust standard errors and diagonally weighted least squares (DWLS) estimation. Sample sizes ranged from n = 12,846 to n = 12,971.

Following the CFA analysis, I ran 20 linear regression models to compare how well each of the proposed variables predicted student self-efficacy and self-concept (in mathematics) at both the baseline year and the first follow-up. Many of the baseline year surveys were completed in the fall of the students' ninth grade year. Since students may not have had much time with their ninth-grade mathematics teachers it is possible that insufficient time had passed to reveal a measurable relationship between mathematics instruction and students' self-beliefs. Including student self-beliefs two years later could help clarify or support any relationship. If the instructional emphases of a ninth-grade mathematics teacher continue to predict student self-beliefs two years later, it suggests a possible longer lasting relationship which continues to have influence even after the student moves on in their education.

Confirmatory Factor Analysis Results

Table 1 shows fit indices for the four single-factor CFA models of conceptual instruction. Each model incorporated items from the mathematics teacher survey where teachers reported their instructional emphases, with items reverse-coded such that higher values indicate greater emphasis. All models employed robust standard errors to account for the non-normality of the data, as indicated by significant multivariate skewness ($b_1p = 11.86$, $p < .001$) and kurtosis ($b_2p = 227.87$, $p < .001$) in Mardia tests.

All models demonstrated acceptable to excellent fit across conventional thresholds. The McQuillen (2016) and Miles (2024) model showed the strongest fit when measured with the CFI (.995) and TLI (.992) while the Gerasimova et al. (2023) model exhibited the lowest RMSEA

(.037) and SRMR (.029) values. Despite these variations, all models met established criteria for adequate fit (CFI > .90, TLI > .90, RMSEA < .08, SRMR < .08), suggesting that the different item selections captured the conceptual instruction construct with comparable psychometric quality. Slightly greater variation appeared in the individual item regression coefficients for each model. The McQuillen and Miles model showed strong regression coefficients for all six items ($\lambda > .55$). In the Yu and Singh (2018) model the two items on emphasizing the history of mathematics ($\lambda = .2$) and preparing students for future study in mathematics ($\lambda = .51$) did not meet this same benchmark. The Ji (2020) model had one item that did not meet this benchmark (i.e., preparing students for future study in mathematics, $\lambda = .48$), as did the Gerasimova et al. (2023) model (i.e., preparing students for business or industry applications, $\lambda = .32$). Overall, the items emphasizing problem solving, reasoning mathematically, and connecting mathematical ideas were the strongest in all models ($\lambda > .72$).

Predictive Validity: Regression Results

To assess the predictive validity of each operationalization, I estimated ordinary least squares regression models predicting four outcomes: ninth grade mathematics self-concept (*x1mthid*), ninth grade mathematics self-efficacy (*x1mtheff*), junior year mathematics self-concept (*x2mthid*), and junior year mathematics self-efficacy (*x2mtheff*). All models controlled for student sex, race (White/Asian vs. other non-White), and socioeconomic status. Factor scores for conceptual instruction were extracted using a ten Berge correction to ensure comparability across operationalizations. Table 2 presents the results for all four dependent variables.

Table 2 Regression Results: Conceptual Instruction Predicting Mathematics Self-Beliefs

Note. CI – Conceptual Instruction. Unstandardized coefficients with standard errors in parentheses. All models control for student sex, race, and socioeconomic status (SES). All sample sizes rounded to the nearest ten per NCES requirement. *** $p < .001$.

Discussion of Findings

The results presented support two principal conclusions. First, no single operationalization of conceptual instruction emerges as definitively superior to the others. While the models exhibit minor variations in fit indices and coefficient magnitudes, these differences are substantively small and do not suggest that one measurement approach captures the construct more accurately or comprehensively. All four models appear statistically similar in their ability to predict self-efficacy but the same cannot be said when predicting self-concept. Three of the models produce nearly identical regression coefficients when predicting self-concept ($\beta = 0.136–0.139$ for ninth grade and $\beta = 0.122–0.127$ for junior year) with overlapping confidence intervals that preclude meaningful distinctions. The Gerasimova et al. (2023) model is not as strong at predicting student self-concept ($\beta = 0.104$ for ninth grade, $\beta = 0.091$ for junior year) but still shows conceptual instruction as a statistically significant predictor with similar patterns of association. This consistent pattern, despite variation in operationalizations, suggests the observed relationships reflect a genuine association with conceptual instruction that is independent of a specific measurement artifact.

The statistical similarity across the models suggests that conceptual instruction is a broad latent construct that can be achieved through a variety of instructional emphases and practices. However, since teaching the history of mathematics and preparing students for future study in mathematics, or business/industry applications had the weakest factor loadings, the inclusion of those items does not seem to be statistically necessary. In fact, three items appeared as the strongest contributors to the conceptual instruction variable. Focusing on reasoning mathematically, connecting ideas in mathematics, and developing problem solving skills consistently had the strongest factor loadings ($.7 < \lambda < .9$) suggesting that conceptual instruction may be increased by focusing solely on these three items. Further investigation should be done to verify this finding, but if conceptual instruction can be achieved through an emphasis on these three objectives, then teacher preparation and professional development programs can become more focused in giving teachers the tools necessary to improve their ability to provide conceptual instruction by engaging students in problem solving, reasoning mathematically, and connecting mathematical ideas.

The second conclusion is that conceptual instruction consistently emerges as a significant predictor of both mathematics self-concept and self-efficacy. Across all regression models the coefficient for conceptual instruction achieves statistical significance at the $p < .001$ level. This robustness holds for both self-efficacy and self-concept at the ninth grade and junior year timepoints, with the strongest association seen when predicting ninth-grade self-concept ($\beta = .139$). Specifically, depending on operationalization, a one-unit change in conceptual instruction predicts a change of .38 to .49 standard deviations in ninth-grade self-concept after controlling for sex, race, and socioeconomic status. This means that if a student with an average level of self-concept in mathematics was moved from a classroom with a minimum level of conceptual instruction to a classroom with a maximum level of conceptual instruction, their predicted self-concept would increase approximately 19 percentile points. For many students, self-beliefs in

mathematics begin to decline significantly in middle school. Improving conceptual instruction could help slow that decline and keep students more engaged and confident in learning mathematics. These results are also noteworthy as conceptual instruction shows a stronger predictive ability than either sex or race when predicting ninth-grade self-concept, suggesting that conceptual instruction may be instrumental in overcoming gender and racial gaps in mathematics.

Admittedly, these conclusions are based on correlational analyses and therefore cannot be used for causal inference. However, the robustness of these associations across multiple operationalizations is particularly noteworthy given the variation in item composition across models. Various operationalizations produce substantively similar results, suggesting that the positive relationship between conceptual instruction and student mathematics beliefs is not contingent on specific measurement choices. This consistency enhances the generalizability of findings across studies employing different operationalizations of conceptual instruction.

The fact that focusing on problem solving, reasoning mathematically, and making connections in mathematics appear to be the most influential components of conceptual instruction, suggests that teacher training and development programs which focus their attention on these three areas could result in essential improvements in providing conceptual instruction in mathematics. Improving conceptual instruction may not only increase student achievement but also bring about improvements in student's self-beliefs. Though the influence of a single teacher has its limits, as more teachers provide increased conceptual instruction, we can harness the power of the reciprocal relationship between self-beliefs and achievement to create a positive upward spiral, resulting in substantial ongoing improvements in both areas.

In sum, these results show that conceptual instruction can be effectively operationalized and that it is a consistent predictor of student self-beliefs in mathematics. Future research should continue to examine the mechanisms through which conceptual instruction influences student self-beliefs and explore whether these relationships vary across student subgroups or instructional contexts.

PROVOKING PRE-SERVICE TEACHERS' EXPERIENCE OF INTELLECTUAL NEED FOR ANGLE MEASURE AND EXPONENTIAL GROWTH

We present a study of pre-service mathematics teachers' engagement with mathematical tasks designed to provoke their experience of intellectual need. Grounded in the theories of Piagetian equilibration and reflecting abstraction, we analyzed three PSMTs' engagement with tasks about angle measure and exponential growth. Findings indicate that carefully engineered impasses—where existing procedural schemes proved insufficient—triggered students' need for new mathematical structures (e.g., radians and partial growth factors). Participants moved from pseudo-empirical generalizations toward structural justifications. These results offer implications for pre-service teacher education by demonstrating how mathematics educators can foster deeper conceptual coherence in future teachers.

Keywords: Problem-Based Learning, Cognition, Design Experiments, Undergraduate Education

Introduction

Problem solving has long been viewed as both an essential source and product of learning mathematics (Carpenter et al., 1993; Erickson, 1999; Hiebert et al., 1996). Students' experience with mathematics, however, is often "problem-free" in the sense that the tasks they encounter primarily consist of routine exercises soluble via the execution of rehearsed skills rather than the application of deep strategic reasoning (Fuller, Rabin, & Harel, 2011). Procedural tasks of this type frequently lack an intellectual challenge, leaving students without a clear mental image of the problem-solving process (Fuller et al., 2011). This reliance on routine exercises is prevalent in undergraduate mathematics instruction (Schoenfeld, 2016) and curricula (Lithner, 2004), which limits students' opportunities to deepen their mathematical understandings through reasoning about novel problems. In contrast, "Problem-laden" activity originates in and is sustained by students' construction of a mathematical task in such a way that they (1) recognize their current knowledge structures as insufficient to solve the problem, and (2) construct an image of particular characteristics of the understanding(s) that would enable them to progress towards a solution. Well-designed problems thus serve as critical catalysts for students to develop their reasoning and build deeper understandings.

Educational psychologists have long emphasized the influence of "desirable difficulties" and "failure-driven scaffolding" in supporting students' mathematical learning (Dewey, 1938; Kapur, 2015; Sinha et al., 2021). Brousseau (1997) argued that authentic problem engagement is necessary to stimulate the evolution of students' conceptions. Similarly, Chevellard's Anthropological Theory of the Didactic suggests that activity is fundamentally motivated by the resolution of experienced difficulties (Bosch & Gascón, 2014). This aligns with Piagetian theory (1971, 1985), which identifies disequilibrium or cognitive perturbation as a vital precondition for the modification of cognitive structures (Tallman & O'Bryan, 2024). Empirical studies support these theoretical frameworks, demonstrating that cognitive incongruities (Graesser et al., 2005), solving problems prior to instruction (Kapur & Rummel, 2012), and

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

navigating impasses (VanLehn, 1988; Kapur, 2014) correlate with constructive reasoning and improved learning outcomes.

Consistent with this broad theoretical tradition of impasse-driven catalysts for cognitive development, Harel (1998) introduced the *necessity principle*, proposing, "For students to learn what we intend to teach them, they must have a need for it, where 'need' refers to intellectual need" (p. 501). Since its inception, intellectual need has emerged as a cornerstone of instructional and curriculum design (Burger & Markin, 2016; Caglayan, 2015; Foster & de Villars, 2015; Koichu, 2012; Leatham et al., 2015; Rabin et al., 2013; Zazkis & Kontorovich, 2016), reflecting a broad consensus that it serves as a necessary catalyst for learning mathematics.

While the literature frequently calls for educators to induce these experiences, there remains a significant gap in practical guidance regarding the design and implementation of *intellectual need-provoking tasks* (IN-PTs). The few recommendations for developing intellectual need-provoking tasks reported in the literature lack detail about how an instructor might design and implement mathematical tasks that support students in experiencing a perturbational state while simultaneously orienting them to extend, modify, or create new knowledge structures. Our study seeks to address this gap.

The central aim of the research reported in this paper is to investigate undergraduate mathematics students' collaborative engagement with IN-PTs. We focused our analysis on the characteristics of methodically designed IN-PTs and instructors' pedagogical facilitation of them that promoted or limited students' experiences of intellectual need. The primary goal of this research is to inform actionable recommendations for the design and implementation of IN-PTs in mathematics teaching. Specifically, our study was guided by the following research question: *What intellectual need did students appear to construct through their collaborative engagement in IN-PTs for angle measure and exponential growth?*

Theoretical Framing

Harel developed and refined the concept of intellectual need in the radical constructivist tradition of impasse-driven catalysts for cognitive development. Compatible with Piaget's theory of the *equilibration of cognitive structures* (Piaget, 1977), a student experiences intellectual need when they enter a state of disequilibrium and feel a sense of curiosity that compels them to develop cognitive resources to resolve their perturbation. Intellectual need is a psychological state with cognitive and affective entailments that results from an individual's conception of a situation as problematic, and their awareness that resolving the situation requires an extension, modification, or creation of knowledge structures. Distinct from other mental states such as confusion or bewilderment, intellectual need results from one's conception of a problematic situation that orients them to engage in conceptual activity intentionally directed toward resolving the situation. Intellectual need is therefore constructive in that it stimulates, rather than impedes, generative reasoning.

Intellectual need is *not* a state that paralyzes reasoning and induces an affective state of interest, which would result only in a student being receptive to *absorbing* the mathematical concepts communicated to them, or the skills demonstrated for them, by a knowledgeable expert (e.g., "I don't know how to do this. I'm ready for someone to show me."). Intellectual need cannot, on the one hand, be conceptualized in a manner consistent with Piaget's idea of equilibration of cognitive structures—and constructivist epistemology generally—while on the other hand promote an exclusively affective state where learning is a product of perception—a premise of empiricist epistemology. Theoretical coherence requires that both the inducement of

intellectual need and the learning afforded by its experience be a product of the actions, operations, abstractions, and generalizations *of the learner*.

For this study, we define intellectual need as an exigence a learner experiences to engage in the mental actions that, through the process of *reflecting abstraction*, form the substrate of cognitive schemes. *Reflecting abstraction* is an abstraction of *actions*, dissociated from the effect they produce and projected to the level of thought (Ellis, Paoletti, & Lockwood, 2024; Piaget, 2001; Tallman & O'Bryan, 2024). This is distinct from *pseudo-empirical abstraction*, which is an abstraction of the properties of objects that have been modified by or created through an individual's actions (Piaget, 1977).

Methods

Experimental Context

We recruited three students (pseudonyms Abbie, Tyra, and Kent) from a large public research university in the Midsouth United States to participate in the study. All participants were mathematics majors with an emphasis in secondary teaching. The participants were enrolled in the same mathematics content course for pre-service secondary teachers taught by the first author for the duration of data collection. Students were invited to participate based on their willingness to collaborate with peers to solve challenging problems and ability to clearly communicate their mathematical reasoning.

Experimental Methods

The research team collected video data during class sessions of participating students' collaborative work IN-PTs addressing the following topics: (1) *constant rate of change*, (2) *angle measure*, (3) *partial growth factors of exponential functions*, and (4) *symbolic representations of exponential functions*. We also collected and scanned students' written work.

The research team also conducted and video recorded individual semi-structured clinical interviews with participating students within one or two days after they had worked in class on a particular IN-PT but before the next class, unless scheduling conflicts occurred. The central focus of these interviews was to further explore each participant's interpretation of the task, their conception of what contributed to its difficulty, and their image of the mathematical meaning(s) that one must leverage to reason productively about the task. In addition to a series of general questions that addressed these foci, we presented each student with strategically-selected video excerpts from their in-class engagement with the task. Presenting these video excerpts during the clinical interviews stimulated students' recall of the emotions they experienced while working on the IN-PTs, the difficulties they encountered, and the problem-solving strategies they employed.

Analytical Methods

We uploaded all video data to Vosaic, a password-protected, strongly encrypted web-based video analysis program. The research team developed a provisional coding scheme that was iteratively extended and refined through several cycles independent coding and discussion, resulting in stable definitions of our codes and subcodes. The research team independently analyzed all video data using our refined coding framework and generated analytical notes attached to each code instance. After this initial analysis, we met to discuss the codes and resolve any discrepancies. To clean the data, we aggregated any temporally-overlapping codes and concatenated the related analytical notes.

We then used the default instance of Microsoft 365 Copilot (running Azure OpenAI Service and Anthropic large language models) to search for patterns in the analytical notes. Copilot created Python code to translate the CSV codes, subcodes, and timestamps into a Pandas data frame, search for patterns among the codes, and augment them with patterns from the comments

based on keywords in the code descriptions. The resulting description included sequences of codes and descriptors along with related comments from the analytical notes. We read these descriptions and compared them with our own notes to construct analytical chronology of the students' collaborative engagement with the IN-PTs.

Intellectual Need-Provoking Tasks

In this report, we include only the results of our analysis of students' engagement with the IN-PTs related to angle measure and partial growth factors of exponential functions. We present these two IN-PTs, describe our design rationale, and discuss our expectations concerning their potential to provoke intellectual need.

Angle measure IN-PT. Tallman and Frank described an essential characteristic of a quantitative conception of angle measure:

> Achieving a quantitative understanding of angle measure involves identifying an attribute of a geometric object to measure and conceptualizing a unit with which—and process by which—to measure it. … One might conceptualize quantifying the "openness" of an angle as measuring the length of the arc of a circle centered at the angle's vertex that the angle subtends. For the measure of the angle to be independent of the size of this circle, the subtended arc must be measured in a unit whose magnitude is proportional to the magnitude of the subtended arc and, by extension, the circumference of the circle that contains it. (Tallman & Frank, 2020, p. 73)

To engender students' experience of intellectual need for a quantitative conception of angle measure, we modified a task initially proposed by Thompson, Carlson, and Silverman (2007). Our IN-PT for angle measure prompted students to sketch a graph of the composite trigonometric function $f(\theta) = \sin(2\cos(\theta))$. We intended students' engagement in this task to provoke their consideration of how $2\cos(\theta)$ could make sense as the argument of the sine function. We expected that students would be familiar with associating angle measures with the input quantity of basic trigonometric functions. However, we anticipated that students would struggle to conceive of $2\cos(\theta)$ as a directed magnitude (measured in units of a circle's radius), which could correspond to the length of an arc an angle subtends, and thus the measure of an angle in *radians*. Figure 1 displays the relationship between the input (θ), argument ($2\cos(\theta)$) and output ($\sin(2\cos(\theta))$) of f.

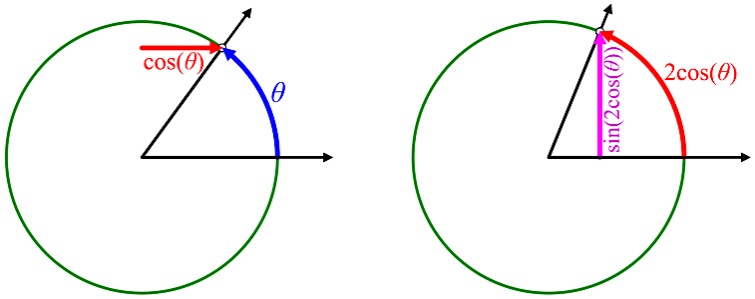

Figure 1: Relationship Between the Input, Argument, and Output of $f(\theta) = \sin(2\cos(\theta))$

Partial growth factor IN-PT. An essential characteristic of exponential functions is that their output values vary proportionally for corresponding inputs that maintain a constant additive relationship (i.e., for an exponential function f, $f(x + \Delta x) = k \cdot f(x)$ for some constant k and fixed Δx). The constant of proportionality relating $f(x)$ and $f(x + \Delta x)$ is defined in terms of the fixed

but arbitrary value of the parameter Δx. Students' understanding of exponential functions is often based on their generalization of the process by which terms in a geometric sequence are generated. Conceptualizing exponential functions as a generalization of repeated multiplication—where the general form of an exponential function ($f(x) = ab^x$) results from representing individual terms in a geometric sequence as a function of their position in the sequence (x), and then affording x with the status of a continuous variable—does not support productive reasoning about the continuity of exponential functions or the relationship between function values for non-integral values of x.

We designed the task below to engender students' experience of intellectual need for a property of exponential function values that is maintained under the continuous variation of these values.

> A biologist first measures the mass of bacteria in an experiment to be 50 micrograms (μg). After 7 hours the mass grows to 100 μg. This pattern of doubling mass occurs every 7 hours following a continuous exponential model. Compute the mass of the bacteria culture (in μg) for the following values of time elapsed since the initial measurement of 50 μg: (i) 7 hours, (ii)14 hours, (iii) 28 hours, (iv) 3.5 hours, (v) 3 hours, (vi) 10 hours, (vii) 47 minutes, (viii) 4.875 hours, and (ix) N hours.

Results

We present our study's results in two sections that respectively describe the students' engagement with each of the IN-PTs.

IN-PT for Angle Measure

Abbie, Tyra, and Kent's initial strategy to construct a graph of $f(\theta) = \sin(2\cos(\theta))$ was to consider how the "2" in the expression $\sin(2\cos(\theta))$ influences the shape of the graph. The students attempted to recall associations between graphical transformations and parameters in the symbolic representation of trigonometric functions.

Tyra proposed that the "2" in the expression $\sin(2\cos(\theta))$ affects the amplitude of the function: "You should be going between two and negative two, right?" In response, Abbie expressed uncertainty when she considered that, although the multiple of two affects the amplitude of $\cos(\theta)$, it might not affect the amplitude of sine since the multiple of two is "inside" the sine function. Abbie proposed, "It could make sine longer," suggesting Abbie's attention to the period of f, not its amplitude.

Students abandoned their effort to apply heuristics for graphical transformations and instead evaluated $f(\theta)$ for integer multiples of $\pi/2$. They expected that plotting these points would reveal enough of the graph's behavior that they could sketch a continuous, differentiable curve connecting these points. However, this approach quickly stalled when the students had to compute $\sin(2)$ and $\sin(-2)$.

After this second impasse, the instructor asked the students to verbalize why this task is difficult. Tyra responded, "there is just, like, multiple things that we have to juggle that makes this relationship unique." Kent described "having cosine inside of sine" as a challenge and explained that they can easily evaluate $\cos(\theta)$ for integer multiples of $\pi/2$, but get stuck trying to evaluate $\sin(2)$ and $\sin(-2)$, which result from evaluating $\cos(\theta)$ for integer multiples of π. Discussing the group's efforts to evaluate $\sin(2\cos(\theta))$ for convenient values of θ, Abbie offered the following reflection:

> We put our radian angles in for theta, in cosine, and then once you get that for cosine, um, it's still in radian measure but without the pi in it. It comes out to two and ends up being slightly what we're not used to. … When you take a radian measure and put it through a trig function, will you get a radian measure out still? [This] is the thing that my brain is trying to figure out if it's true or not. Because then that helps me reason that if what I'm putting into sine makes sense. … The thing is, when you're graphing these [sine and cosine functions], I realized that the one and negative that you're oscillating between, like, is that in radian measure? The *y*-value that we get out? … We know this [θ] is radians but what is this [$2\cos(\theta)$]? … So then whatever we're putting into sine doesn't make sense to put into sine.

The instructor asked the students to clarify why it is a concern for values of $2\cos(\theta)$ to be inputs of sine. Tyra offered the following explanation:

> Like [Abbie] was saying, … when you do cosine of zero and you get one as the output, that one corresponds to, like, your length of your radius of your circle. … And so you wouldn't plug a radius unit back into sine. You need to plug in radians. So you would have to convert that.

We interpret the students' consideration of the units associated with the input (θ) and argument ($2\cos(\theta)$) of f to signify an important advance in their experience of intellectual need. The primary perturbation expressed by students in Group A throughout their engagement in the angle measure IN-PT was how to interpret "cosine inside of sine." We earlier cited Tallman and Frank's (2020) criteria of a quantitative conception of angle measure, which includes, "identifying an attribute of a geometric object to measure and conceptualizing a unit with which—and process by which—to measure it" (p. 73) Abbie, Tyra, and Kent's collaborative work on the IN-PT culminated in their grappling with determining the *quantity* (i.e., measurable attribute) of which θ is a measure and $2\cos(\theta)$ is a measure, and whether $2\cos(\theta)$ could represent a value in *radians*.

IN-PT for Partial Growth Factors

Tyra immediately associated the growth rate with the expression 2^n, where one-unit variations in n correspond to seven-hour intervals of elapsed time. All three students quickly computed the mass of the bacteria culture after seven hours, 14 hours, and 28 hours by repeatedly doubling the initial mass of 50 micrograms for each successive change of seven-hours of time elapsed. When considering how to determine the mass of the bacteria culture after three hours, Tyra proposed to compute $50\left(\frac{3}{7}\right)(2)$ (i.e., "Fifty of three-sevenths of two"). She reasoned that since three is three-sevenths of seven, then the mass of the bacteria culture after three hours is computed by multiplying the initial 50 micrograms by three-sevenths of two (the seven-unit growth factor). The students computed $50\left(\frac{3}{7}\right)(2) \approx 42.8571$, and upon realizing that this value is less than the initial 50 micrograms, decided to add this value to the initial mass. Tyra noticed that the resulting sum (92.8571μg) is close to the mass of the bacteria after seven hours (100 μg), and concluded that this cannot make sense as a value for the mass of the bacteria after only three hours—a concern echoed by Abbie and Kent.

Tyra then suggested that the expression $50(2)^{\frac{3}{7}}$ might represent the mass of the bacteria culture after three hours, asking, "Could it be fifty times two to the three-sevenths? Is that where my three-sevenths comes in instead?" She reasoned that since 2^n models the growth of the bacteria culture, and since n represents increments of seven hours, it makes sense for 3/7 to be the exponent of 2: "Earlier how I said it was fifty times two to the n for whatever increments you

have of seven. So if we have three out of seven there, that should be two to the three-sevenths instead of three-sevenths times two." Abbie described 3/7 in the exponent as representing "a fraction of the doubling," but then admitted, "I don't think that makes sense." The three students computed $50(2)^{\frac{3}{7}} \approx 67.3$ and concluded that this solution is reasonable in the context of the situation. They similarly computed the mass of the bacteria culture after 47 minutes by evaluating $50(2)^{\frac{47}{420}}$. To this point in the students' engagement in the task, they did not seem to reason about the relationship between *n*-unit growth factors and partial growth factors. Instead they appeared to have pseudo-empirically abstracted from their prior activity the symbolic form [Initial Mass]$(2)^{[N/(\text{Doubling Interval})]}$, where *N* represents the elapsed time (in hours) for which the expression represents the mass of the bacteria culture. After having engaged in this pseudo-empirical abstraction, all three students quickly and correctly computed the mass of the bacteria culture for each value of time listed in the task and correctly represented the mass of the bacteria culture after *N* hours.

The instructor prompted the students to justify why three-sevenths is an exponent of two instead of a multiple. Tyra explained, "It was fifty times two to the three-sevenths because it was an exponential relationship." We interpret Tyra to have reasoned that since the mass of the bacteria culture grows *exponentially*, seven-hour intervals of elapsed time must be represented in the *exponent*, as $50(2)^n$ represents the mass of the bacteria culture after $7n$ hours. Tyra's response again indicates that her understanding of the expression $50(2)^{\frac{t}{7}}$, where *t* represents time elapsed in hours, was not based on an abstraction of the relationship between an *n*-unit growth factor and partial growth factors. To support this abstraction, the instructor asked, "How is the mass of the bacteria changing every hour?"

Tyra computed $50(2)^{\frac{1}{7}} - 50 \approx 5.2$ and claimed, "It changes by 5.2 micrograms per hour." Although having successfully defined the mass of the bacteria culture as a function of the number of hours elapsed, Tyra's comment reflects an image of a constant growth rate (fixed changes in mass for uniform successive changes in time elapsed), providing further evidence that the expression she defined to represent the mass of the bacteria after *N* hours, $50(2)^{\frac{N}{7}}$, was based on a pseudo-empirical abstraction of her reasoning about computing the mass corresponding to integer multiples of seven hours of time elapsed. Tyra paused for several seconds and said, "I don't think that's right." The three students sat quietly in thought for 30 seconds. Then Tyra proposed, "I think it would change by two to the *x* over seven per hour, or just two to the one over seven." Despite Abbie's observation that "It's growing a little faster every hour," Tyra and Kent continued to consider how to represent additive changes in the mass of the bacteria for successive one-hour changes in elapsed time.

The three students described the meaning of $2^{\frac{1}{7}}$ as, "The amount of change in mass of the bacteria in one hour." It was not clear whether the students conceptualized $2^{\frac{1}{7}}$ as a growth *factor* (i.e., a constant of proportionality relating the mass of the bacteria culture at some moment and the mass seven hours later), or as representing an *additive change* in mass, so the instructor prompted them to specify how they conceptualized "amount of change." Referring to the meaning of the expression $2^{\frac{2}{7}}$, Tyra responded, "Like the difference from the initial measurement to the two hours elapsed, in the bacteria. There's a difference in what the original mass was versus this." The instructor then proposed that the function $y = f(t)$ gives the mass of the bacteria culture (in micrograms) as a function of time elapsed (in hours). He asked the students to state whether the equation $f(2) - f(0) = 2^{\frac{2}{7}}$ accurately represents their thinking. Tyra responded,

"Yes" while Abbie and Kent nodded in agreement. The students also agreed that the equation $f(4) - f(2) = 2^{\frac{2}{7}}$ is correct. The instructor finally prompted the students to consider whether $f(n+2) - f(n) = 2^{\frac{2}{7}}$. After a moment of thought, all three students agreed that the equation is correct.

The equation $f(n+2) - f(n) = 2^{\frac{2}{7}}$ is not correct for an exponential function f. The instructor attempted to support students' multiplicative reasoning about the relationship between function values $f(n+2)$ and $f(n)$ by asking, "If you know the mass of the bacteria after 26 hours, how would you compute the mass of the bacteria after 28 hours?" All three students spent a few minutes independently testing on their calculators different possible ways to calculate the mass of the bacteria culture after 28 hours given the mass of the bacteria culture after 26 hours. That they needed to do this demonstrates that until this moment, the students likely had not conceptualized the relationship between measures of the mass of the bacteria culture corresponding to different values of time elapsed. Tyra then clarified her thinking: "So then, when we said earlier, when we were trying to calculate differences, and it was two to the two-sevenths, whatever, between $f(4)$ and $f(2)$, that wouldn't necessarily– because it's by a factor of it; it's not additive!" This reflection prompted Tyra and Abbie to conclude that the mass of the bacteria culture increases continuously within seven-hour intervals of elapsed time, and that this increase occurs at a non-constant rate.

The students' lengthy consideration of whether expressions of the form $2^{\frac{N}{7}}$ represent *differences* in the mass of the bacteria culture, or *factors* relating measures of the mass corresponding to different values of elapsed time, contributed to a key shift in their thinking. When asked what $2^{\frac{N}{7}}$ represents in the context of the situation, Tyra claimed, "That is the factor at which the mass of the bacteria culture changes per hour" and Abbie clarified the meaning of N, "with the N being the number of hours." The students later expressed that $2^{\frac{N}{7}}$ represents the constant ratio $\frac{f(t+N)}{f(t)}$ where t represents a varying time elapsed in hours and N represents a fixed but arbitrary change in time (in hours).

Discussion and Conclusion

Throughout the students' collaborative engagement in both IN-PTs, the impasses they experienced were not side-stories—these impasses *organized the trajectory* of the students' conceptual activity and cognitive reorganization. The students' confusion sustained their inquiry into foundational meanings (e.g., growth rates relating to differences versus factors); their curiosity stimulated productive algebraic generalization; their surprise prompted reconsideration of basic assumptions and critical evaluation of their prior knowledge. Our findings demonstrate that students' experience of disequilibrium does not represent a "failure" but can be a vital precondition for their conceptual learning of mathematics.

The results of our study suggest that instructional designs for undergraduate mathematics courses for pre-service secondary teachers should include opportunities for students to experience very specific impasses that facilitate their progression through an explicit learning trajectory. The IN-PTs we designed for this research serve as models of tasks for which students' uncritical application of rehearsed procedures yields contradictions that can provoke students' experience of intellectual need.

We encourage researchers to extend the findings we report by examining the educative value of students' experience of intellectual need as they participate in classroom instruction related to the mathematical concepts necessitated through students' engagement with an IN-PT.

EXPERIENCES SHAPING MOTIVATIONS FOR GRADUATE STUDY IN MATHEMATICS: A QUALITATIVE STUDY OF PERSONAL STATEMENTS

Sophia Towle
University of New Hampshire
Sophie.Towle@unh.edu

Orly Buchbinder
University of New Hampshire
Orly.Buchbinder@unh.edu

Concerns about the leaking pipeline from undergraduate to graduate study in mathematical sciences raise important questions about what shapes students' decisions to pursue advanced degrees. Understanding the experiences and motivations of prospective graduate students is essential for supporting them and sustaining a robust mathematical science workforce. This qualitative study analyzes personal statements of 29 applicants to mathematics and statistics graduate programs, focusing on the experiences they describe and how they position themselves in relation to them. Using the lens of pivotal experiences and personal agency, we find that applicants rarely frame a single experience as pivotal; instead, they emphasize coursework, research, and teaching as motivational factors. The applicants also tend to portray themselves as active or collaborative participants, actively shaping their decisions to pursue graduate study.

Keywords: Graduate Study in Mathematics, Pivotal Experiences, Agency, Motivation

The decision to pursue graduate education in the mathematical sciences—including pure mathematics, applied mathematics, mathematics education, and statistics—is a significant milestone in an individual's academic and professional trajectory. Although many students complete undergraduate degrees in mathematics or related fields, only a subset ultimately pursue graduate study. Understanding why some individuals persist in the mathematical sciences is important for strengthening graduate programs and supporting prospective graduate students, as well as for sustaining a robust mathematical sciences workforce (National Academies of Sciences, Engineering, and Medicine [NASEM], 2016).

A growing body of literature has examined motivations for graduate study across disciplines. Researchers identify both internal factors, such as intellectual curiosity and the desire to contribute to knowledge or society (Incikabi, 2013; Kowalczuk-Waledziak et al., 2017), as well as external factors, including career advancement and societal pressures (Hinkle et al., 2014; Ivankova & Stick, 2007). In mathematics education research, emerging work has begun to explore these motivations in more discipline-specific ways (e.g., McEldowney et al., 2024; Towle & Buchbinder, 2026).

While prior studies document a range of motivational factors (e.g., Towle & Buchbinder, 2026), less is known about the experiences and forms of agency individuals interpret as shaping their interest in and desire to apply to graduate study in mathematics. This study addresses this gap by examining personal statements in graduate admissions applications to explore how applicants construct narratives of personal experiences and agency they highlight as affecting their pathways to graduate study. Specifically, we ask: *What types of experiences do applicants to graduate programs in the mathematical sciences describe as influential in their mathematical journey and decisions to apply to graduate school?*

Literature Review

Research on graduate school intentions, not necessarily specific to mathematics, highlights that students' educational decisions are shaped by a combination of internal and external motivations (Gibbons & Schoffner, 2004; London et al., 2014; Teowkul et al., 2009). External

motivations typically center on professional gain, career advancement, job security, and higher salaries (Hinkle et al., 2014; Ivankova & Stick, 2007; Teowkul et al., 2009). Advanced degrees are often required in academia and in many industry positions, making alignment with career goals a strong predictor (Basalla & Debelius, 2014; Towle & Buchbinder, 2026). External influences, such as mentor and faculty encouragement and social influences from family and peers, can also shape students' awareness of and motivations for particular fields, programs, or research opportunities, leading individuals to consider graduate studies or career paths they had not previously envisioned (Brailsford, 2010; Sherman, 2021).

While external influences play an important role, internal motivations often become central as students develop clearer academic and career goals. Internal motivations, such as enjoyment of research, seeking intellectual challenges, and drive for academic achievement, are linked to feelings of personal satisfaction, self-efficacy, and a sense of purpose (Kowalczuk-Waledziak et al., 2017; Teowkul et al., 2009). In mathematics specifically, the pursuit of knowledge, research interests, and appreciation for the discipline itself (i.e., mathematics, statistics) have been shown to motivate students to pursue advanced study (Towle & Buchbinder, 2026).

Beyond identifying the types of motivational factors, considerably less is known about the experiences applicants describe as influential in shaping their interest in graduate study. Some studies suggest that internal motivations are shaped by personal experiences that help individuals discover their passions (e.g., Løvoll et al., 2017; Valas & Søvik, 1993). In mathematics, such experiences may include coursework, research involvement, or meaningful interactions with faculty. However, little is known about how specific experiences shape students' motivations to pursue graduate study. This study aims to address this gap.

Conceptual Framework

To address our research question, we draw on two complementary constructs: pivotal experiences and personal agency. Together, these constructs support an analytic approach attending to both *what* applicants describe in their personal statements and *how* they position themselves in relation to those experiences. Some experiences described in personal essays appear to be more influential in shaping applicants' trajectories. We refer to such experiences as *pivotal* and define them as events that fundamentally redirect an individual's life course. Central to such experiences is a pivotal moment—often an "aha" realization—through which an individual gains a new perspective that meaningfully alters their trajectory (Giorgi, 2011; Maclennan, 2015). Pivotal experiences are characterized by a clear "before" and "after" state, often initiating lasting changes in priorities, beliefs, or circumstances, and functioning as a defining moment in one's life (Giorgi, 2011).

The second analytic dimension concerns how individuals describe their relationship to the experiences they recount. To examine this dimension, we draw on the concept of *agency*. Following Abele et al. (2008), we define agency as "a person's striving to be independent, to control one's environment, and to assert, protect and expand one's self" (p. 1204). This is commonly understood as the experience of generating one's own actions and outcomes (Haggard & Tsakiris, 2009). Agency extends beyond overt action to include the ability to set goals, make decisions, and act in ways that help achieve them (Markus & Kitayama, 2003). Importantly, agency is not limited to an action initiated by an individual. It can emerge in response to a situation where a person must act and navigate in their environment (Holland et al., 2003). The degree and form of agency may vary across situations, reflecting differing levels of choice and opportunity (e.g., Hansen, 2022). Therefore, we conceptualize agency along a continuum: high agency, shared agency, and limited (or responsive) agency (Adler et al., 2008; Hansen, 2022).

Taken together, pivotal experiences and agency provide a framework for analyzing both the significance of experiences and the degree of agency applicants assume in those experiences. The six cells of our analytic framework (Table 1) describe the intersection of various forms of agency (high, shared, and limited/responsive) with whether an experience is portrayed as pivotal.

Table 1: Theoretical Framework for Applicants' Experiences

	High Agency	Shared Agency	Limited / Responsive Agency
Pivotal Experience	Applicant initiates and pursues a transformative experience, presenting a clear turning point driven by their own decisions.	Experience becomes pivotal through collaboration or external encouragements; the applicant participates meaningfully.	Life-altering event outside of applicants control that produces a clear turning point; the applicant's response shapes their path.
Non-Pivotal Experience	Applicant intentionally seeks a meaningful experience that supports growth without redirecting their trajectory.	Experience is suggested or facilitated by others and supports development without a major turning point.	Experience, not initiated by applicant, that subtly shapes their perspective without a dramatic shift.

This integrated framework enables us to systematically interpret how applicants make sense of their experiences. Specifically, it distinguishes experiences that applicants actively initiate and frame as transformative, those that become pivotal through collaboration or guidance, and those that arise outside their control but elicit meaningful responses. Importantly, we consider *all* experiences described in personal statements meaningful and influential. Although only those that produce a clear "before-and-after" shift were deemed pivotal, non-pivotal experiences are still thought to contribute to applicants' development and motivation to pursue graduate study in mathematics. Additionally, in this study, agency serves as a lens for interpreting how applicants present their experiences in personal statements—how they portray their roles in initiating, shaping, or responding to those events. Attending to agency thus provides insight into how applicants' narrative self-positioning relates to their motivations and aspirations for advanced study in mathematics. Taken together, this approach provides a nuanced lens for understanding how applicants portray their role in shaping, responding to, or being shaped by their experiences.

Methods

Data Sources and Collection

The data for this study are drawn from personal statement essays submitted by applicants to graduate programs in mathematics and statistics at a mid-sized public research university located in the Northeastern United States. These essays are a central component of the application process and require applicants to describe their academic interests, professional aspirations, prior research or work experience, and the motivations for pursuing graduate study. As such, the statements provide rich qualitative data and have been used in general higher education research to provide insight into how applicants frame their educational trajectories and future goals (e.g., Forister et al., 2011; Kuncel et al., 2020; Wouters et al., 2014). In mathematics education,

personal statements remain a rarely utilized data source despite offering a unique lens into the motivations and experiences of prospective graduate students in the mathematical sciences.

Personal statements are *purposeful narratives*, meaning that the experiences included in these essays are those that applicants likely consider important in their decision to pursue graduate mathematics or statistics, or they felt would strengthen their applications. However, personal statements are written for a specific audience and purpose, in which applicants strategically frame their experiences to present themselves as viable candidates for the graduate program. These potential effects of social desirability should be considered when interpreting the findings.

Participants

All applicants from 2015 to 2024 were invited to participate. For consenting participants, the second author, a graduate admissions committee member with access to application materials, compiled personal statements and background information, including gender, application year, intended program, and citizenship status. Race and ethnicity were excluded because this data was optional and unavailable for many participants.

The sample analyzed in this paper, consists of 29 admitted applicants to eight graduate programs in the Mathematics and Statistics Department, collectively referred to as the "mathematical sciences." The sample includes 20 doctoral students and 9 master's students. Doctoral programs include Applied Mathematics (n = 3), Statistics (n = 8), Pure Mathematics (n = 6), and Mathematics Education (n =3). Master's-level programs include Applied Mathematics (n = 4), Statistics (n = 3), Pure Mathematics (n = 1), and a Master of Science for Teachers (MST; n = 1). Fourteen participants identified as male and 15 as female; 20 reported U.S. citizenship status, seven non-U.S., and two reported dual citizenship (including U.S.).

Data Analysis

The unit of analysis was a *distinct narrated experience* in each personal statement, ranging from one sentence to several paragraphs. Experiences were defined by how applicants structured their stories, rather than by an attempt to catalog their entire academic careers. In some cases, applicants described multiple events leading up to a single decision or turning point. When these events were mentioned as a background for a larger experience, they were not coded separately. Instead, coding focused on the experience that the applicant positioned as central or meaningful within the story (e.g., a decision to change majors). This approach prioritized the applicant's narrative emphasis over accounting for every single experience discussed.

In line with the aims of the study—to examine the types of experiences applicants describe as influential, and how they position themselves in relation to those experiences—each identified experience was coded along the two dimensions of our analytical framework: (1) experience type and (2) degree of agency. Table 2 shows examples of each of the six codes.

Table 2: Examples of Coding Experiences in Personal Statements

Experience Type	Degree of Agency	Example
Pivotal Experience	High Agency	During my MS semester studying fashion … My work excelled and the professors were encouraging, saying that I had talent, but I was filled with an unreasonable dissatisfaction … My love of calculus won over my love of fashion, and I switched my focus to mathematics. (Applied Mathematics MS)

	Shared Agency	I have been interested in proving mathematical theorems ever since high school … This started in my sophomore year when I had an amazing Math teacher. I credit [this teacher] with instilling in me the excitement I have about mathematics … The enthusiasm that was shared in this class has never diminished. (Mathematics PhD)
	Limited / Responsive Agency	My passion for statistics has stemmed from my arduous years searching for a diagnosis for a rare medical condition from which I suffered in college. (Statistics PhD)
Non-Pivotal Experience	High Agency	I wanted to learn upper-level mathematics at a university and contribute research in a mathematical field. At [university], I started to do just that. I took classes in Algebra, Analysis, Topology, and applied math. (Mathematics Education PhD)
	Shared Agency	Early in my sophomore year, I became a research assistant working in dendrochronology with one of [faculty member's] doctoral students. (Statistics MS)
	Limited / Responsive Agency	My biggest prize [was] to see the pride in my mother's eyes when she talks about how I managed to graduate from the best university in the state and when she talks about my academic achievements … This undoubtedly fills me with joy and pride. (Statistics PhD)

Note that an experience was identified as pivotal when the author clearly articulated a "before-to-after" transition. Thus, the identification of pivotal experiences relies on the text's narrative construction and the presence of an explicit or strongly implied shift in direction.

Results

Across the 29 personal statements, applicants described a diverse range of experiences, averaging five distinct experiences per statement. Overall, 142 experiences were coded. Below, we present the results according to the six categories of our analytic framework.

Pivotal Experiences with High Agency

Experiences coded as pivotal and high agency counted for 4.9% of instances, characterized by a clear "before-and-after" shift that applicants positioned as redirecting their career or life trajectories. This was driven by self-recognition leading to deliberate action, such as switching majors, recommitting to mathematics, or discovering a deep personal affinity for the subject. For example, one applicant described how realizing their love for mathematics prompted them to shift their major, saying, "I switched my focus to mathematics" (see Table 2). Another applicant described rediscovering their love for mathematics after leaving it, writing, "I made the mistake of leaving the world of mathematics behind once […] it is not a mistake I intend to make again."

A few applicants also described early self-driven experiences with mathematics. For instance, one wrote, "When I was in elementary school, I strove to keep up with my older brother's math homework […] Due to this, I came to love being constantly challenged mathematically at a young age." Across these accounts, applicants present themselves as the ones who recognized the misfit and chose to redirect their trajectory toward mathematics.

Pivotal Experiences with Shared Agency

Pivotal experiences with shared agency accounted for 6.3% of experiences. These involved transformative "before-and-after" moments facilitated by others, often faculty, through courses or advising. Some experiences centered on encounters with mathematical content or instruction.

For instance, one applicant who described taking an Abstract Algebra course stated, "I knew it was different than the other math classes I took." This applicant described how discovering a new understanding of proofs eventually led them to pursue research in this area. We coded this as an instance of shared agency because it was strongly implied that the course was required for the major, rather than chosen by the individual, yet the applicant actively engaged with and built on it to the point that it became a pivotal experience for them.

Other applicants highlighted influential teachers whose enthusiasm sparked lasting interest in mathematics, as one applicant wrote, "I have been interested in proving mathematical theorems ever since high school in trigonometry…when I had an amazing Math teacher." This individual goes on to say, "I credit [this teacher] with instilling in me the excitement I have about mathematics […] The enthusiasm that was shared in this class has never diminished but has expanded to more topics within mathematics." In these narratives, the initial opportunity was provided by someone else, but applicants actively engaged with it and incorporated it into their trajectories, demonstrating shared agency in pivotal experiences.

Pivotal Experiences with Limited or Responsive Agency

Pivotal experiences with limited or responsive agency accounted for 5.6% of coded instances. They describe major life events outside applicants' control that nonetheless reshaped their educational trajectories. Half of these experiences involved health-related issues, often causing individuals to pause their education and, consequently, realize how much they missed mathematics, as one wrote, "taking a year off from learning mathematics made me feel like I was missing something in my life." Another applicant described how a prolonged medical challenge shaped their academic interests: "My passion for statistics has stemmed from my arduous years searching for a diagnosis for a rare medical condition from which I suffered in college."

Other experiences in this category involved family loss or formative early-life events. One applicant wrote, "The hardest puzzle I have ever faced was my father's death," explaining that this initiated a lifelong "quest to ask questions and search for answers," ultimately drawing them toward mathematics. Another described being pulled out of class in elementary school, reflecting: "My interest in math education ironically began the moment my father pulled me out of my math classroom." In these cases, applicants do not claim agency in the event; instead, they frame their *responses* as central to developing motivation and engagement in mathematics.

Non-Pivotal Experiences with High Agency

Non-pivotal experiences with high agency accounted for 43.7% of all coded experiences, making this the most frequent category. These narratives describe experiences in which applicants intentionally pursued and strengthened existing interests, skills, or commitments as part of an ongoing developmental trajectory, rather than through a single dramatic turning point. Nearly half of the experiences in this category involved mathematical content or coursework (22.5%) and teaching (21.0%). For example, one applicant wrote,

> The passion I currently have in algebra began at [university] when I took Abstract Algebra. This course seemed to come more naturally to me. … As a result, when I became a graduate student I made every effort to take as many algebra courses as possible while still satisfying my degree requirements. I managed to take separate courses in Ring Theory, Group Theory, and Field Theory, and thus, my foundation in algebra was immensely strengthened.

Here, the applicant emphasizes deliberate, self-initiated actions ("I made every effort") that strengthen an emerging interest in algebra that originated in their undergraduate coursework. Applicants similarly described engaging in additional advanced coursework, pursuing independent learning, and reflecting on their teaching practice. For example, one applicant to the

Mathematics Education PhD program wrote, "I have worked honing the craft of teaching as a high school math teacher at a small private boarding school."

Across these accounts, the applicants position themselves not simply as students progressing through coursework, but as mathematical doers and teachers who actively develop, apply, and share their expertise. Their narratives depict ongoing participation in the practice of mathematics rather than passive movement through degree requirements. Together, these experiences illustrate sustained, intentional engagement with mathematics beyond minimal expectations. Applicants frame their trajectories as self-directed and purposeful, highlighting the choices they made to deepen understanding and reinforce their commitment to the discipline over time.

Non-Pivotal Experiences with Shared Agency

Experiences in this category accounted for 38.0% of all codes and included non-pivotal experiences facilitated by others. The most common themes were research (40.7%), followed by coursework (22.2%) and teaching (16.7%). While similar to the previous category, they differed in the level of agency. Applicants frequently referenced working "under" or "with" a professor or as part of a group, indicating shared responsibility and guidance. One applicant wrote, "I worked as a research assistant under [faculty member]," while another described, "My group's research explored the inner workings of the quasi-random Polya Board."

Applicants sometimes attributed their developing interests in specific mathematical areas to professors. For example, one applicant wrote,

> At undergraduate level, my interests became more focused … Analysis and its applications and Mathematical Modeling truly captured my interest. I was fortunate to have innovative and distinguished professors, and I performed well in all these subjects. Therefore, I have chosen to specialize in Applied Mathematics and Computational in Mathematics.

In this quote, the applicant emphasizes gratitude for their professors ("I was fortunate to have") whose instructional practices helped refine their interests, highlighting a collaborative developmental process. Teaching experiences in this code typically involved a teaching assistant position, for which the applicant stated they were given this opportunity, sometimes by a professor. For example, one applicant wrote, "I assumed the role of teaching assistant […] coordinated by [faculty member] in my junior year." Across these narratives, applicants frame mentors and instructors as central facilitators in these experiences, highlighting how guidance and collaboration supported their learning and preparation for graduate study.

Non-Pivotal Experiences with Limited or Responsive Agency

Experiences in this category only accounted for 1.4% of all codes (two instances). They were non-pivotal and marked by limited or responsive agency, in which applicants described reacting to external circumstances rather than initiating them. One applicant reflected on the pride their mother expressed in their academic achievements, emphasizing their emotional response, stating, "This undoubtedly fills me with joy and pride." Another applicant described being approved to study statistics at their undergraduate institution, framing entry into the academic environment as something that happened to them ("I started my contact with the academic environment"). These few instances highlight experiences that, without being framed as agentic or pivotal, were still portrayed by the applicants as influential in pursuing graduate study.

Summary and Discussion

Overall, relatively few experiences were categorized as pivotal (accounting for 16.9% of all codes, regardless of agency level) in the applicants' essays. When pivotal experiences did occur, they most often involved realizations of a deep affinity for mathematics, mentor-initiated

opportunities that reshaped goals, or major life events, all of which prompted self-reflection and redirection toward graduate studies. Some pivotal experiences were deeply personal and emotional. The fact that individuals chose to include them in their personal statements (and consented to have these statements analyzed) may suggest that the applicants viewed their decision to pursue graduate programs in mathematics as a crucial part of their life journey, intrinsically tied to other significant life events, rather than a simple career choice.

Most experiences in the personal essays were non-pivotal yet meaningful (accounting for 83.1%). These experiences commonly involved coursework, research, and teaching and were frequently narrated with either high agency, emphasizing personal initiative, or shared agency, emphasizing the role of mentors and structured opportunities. This aligns with prior work showing that continued involvement in coursework and research helps students develop interest and intentions to pursue graduate study (Ivanka & Stick, 2007; Tennant, 2004). The relatively low frequency of pivotal experiences suggests that applicants rarely frame their pathway to graduate study as the result of a single dramatic turning point. Instead, their narratives portray graduate aspirations as emerging through the accumulation of multiple experiences over time. This concurs with prior research indicating that individuals hold multiple, interacting motivations for pursuing graduate study (e.g., Teowkul et al., 2009; Towle & Buchbinder, 2026).

Agency emerged as central across narratives (high agency experiences accounting for 48.6% and shared agency experiences accounting for 44.4%), meaning that applicants positioned themselves as active participants in shaping their educational trajectories, while also often acknowledging the importance and influence of others in facilitating opportunities. This reflects a relational view of agency: it can arise both from an individual's actions and from interactions or opportunities provided by others (Holland et al., 2003). Additionally, this aligns with previous work that identifies external influences such as mentoring and encouragement as central to graduate school aspirations (Incikabi, 2013; Kowalczuk-Waledziak et al., 2017; Sherman, 2021).

It is important to note the limitations of this study. The sample is drawn from a single mid-sized public research university in the Northeastern United States, limiting the generalizability of this work. Additionally, personal statements are self-presentational documents written for an admission audience. While they provide insight into how applicants frame and interpret their experiences, applicants may selectively emphasize experiences and personal qualities they perceive as desirable, meaning these narratives may not fully capture all factors that influenced their decision-making to pursue graduate study. Thus, the experiences analyzed here reflect constructed accounts shaped by the admissions context and strategic self-presentation. Furthermore, although our broader dataset includes 75 applicants, both admitted and non-admitted, this study focuses on 29 admitted individuals to examine experiences associated with successful entry into graduate programs. Future work will extend this analysis to provide a more comprehensive understanding of experiences shaping graduate study decisions.

This study contributes to the field in multiple ways. The analysis of personal statements provides insight into applicants to mathematical sciences programs, addressing a knowledge gap. Findings suggest that graduate aspirations often emerge through accumulated experiences, underscoring the importance of sustained access to authentic mathematical experiences, such as advanced coursework, research and teaching—all of which support the development of students' skills, interests, and motivation. Future research should include multiple institutions and program types to explore how contexts shape applicants' experiences and motivations for graduate study in mathematics. Collectively, results of these studies can help researchers and educators address the leaking pipeline from undergraduate to graduate study in mathematical sciences.

STUDENTS' GOALS, BELIEFS, AND ENGAGEMENT PATTERNS IN AN INTRODUCTION TO PROOF COURSE

Chelsey Van de Merwe
Oklahoma State University
cvandem@okstate.edu

Michael Oehrtman
Oklahoma State University
michael.oehrtman@okstate.edu

The shift to proof-based mathematics in US universities often takes place in an introduction to proof (ITP) course. Existing literature describes the nature of these courses and the difficulties students experience in the course, but little is known about how students' goals, beliefs, and conceptions of proof develop throughout an ITP course (David & Zazkis, 2020). Five students participated in a longitudinal study examining how ITP students' goals, beliefs, and engagement patterns evolved during an ITP course. Students' goal orientations (Dweck & Leggett, 1988) were seen to be malleable throughout the course with most students starting the semester with learning goals. Students adopting performance goals engaged in maladaptive behaviors such as relying on AI. Student beliefs about the purpose of mathematical proof varied; all students believed verification and explanation to be key purposes of proof.

Keywords: Undergraduate Education, Reasoning and Proof, Advanced Mathematical Thinking

The comprehension and construction of mathematical proof is central to undergraduate mathematics education in the United States. However, many students struggle to transition from primarily computational mathematics to proof-centered mathematics (Moore, 1994). To support students in this transition, many US universities designate an introduction to proof (ITP) course focused on enculturating students into the community of proof-based mathematics (David & Zazkis, 2020). We conducted a longitudinal study examining students' goals, beliefs, and engagement patterns during an ITP course. In this report we summarize the results of the research questions:

1. How do students' goals and beliefs about mathematics and mathematical proof interact with the way they engage in an ITP course?
2. What are ITP students' goals and beliefs about mathematics and mathematical proof? How do these goals and beliefs evolve during an ITP course?

Literature Review

The purpose of ITP courses is to teach logic rules, proof structures, set theory, and, in some cases, basic content from one or more branches of mathematics (David & Zazkis, 2020). David and Zazkis categorized ITP courses in the US into three categories: standard only, standard + topic, and topic-based. Standard only ITP courses, which accounted for 41% of their data, focus on teaching skills necessary for proof comprehension and production such as understanding symbolic logic, quantifiers, set theory, and truth tables. While mathematical content is necessarily used in these classes, it is not the course's aim to introduce new mathematical content to students. Standard + topic courses (40% of ITP courses surveyed) teach the same topics as the standard only course and include an exploration of a new mathematical topic, frequently discrete mathematics. The exploration of new mathematical content often occurs at the end of the term. Topics-based courses (19% of ITP courses surveyed) focus on teaching a specific mathematical topic, most commonly analysis, and include the development of mathematical argumentation as a

goal of the course. The data for this study was gathered in a standard + topic course where the topic was abstract algebra.

Mathematics education researchers have struggled to produce a definition of proof that draws an indisputable line between proof and non-proof (Stylianides et al., 2017). This problem is sometimes called the "hard boundary problem" (Czocher & Weber, 2020). For example, there is debate about whether non-syntactic proof, such as computer-generated proofs, picture proofs, or probabilistic proofs qualify as proof (Aberdein, 2009). A definition of proof should provide justification for the inclusion or exclusion of such arguments. The lack of clarity about a definition of proof may cause confusion for newcomers to the community.

Many definitions of proof proposed by researchers are couched in satisfying one of the many purposes a proof can fulfill. Proof can serve a variety of purposes for mathematicians including verification, explanation, systematization, discovery, communication, construction, exploration, and incorporation (Hanna, 2000). Hanna suggests that students entering the mathematical community should primarily engage with proofs serving the two fundamental purposes of verification and explanation. Instruction in introductory courses should reflect these two primary purposes of proof.

While the norms of proof writing, and consequently the definition of proof, held by distinct communities may differ, the values that underly those norms are likely similar (Dawkins & Weber, 2017). For example, most communities engaged with mathematical proof would likely agree that proof should increase mathematical understanding. A proof submitted for publication may be held to the norm that routine calculations or obvious justifications be omitted from the proof; however, in an ITP course a student may be required to show such calculations and justifications. It is critical to understand the norms established within the community from which a proof originates. Instructors of the same course at the same university may even have differing goals and beliefs about norms that should be adopted by students. We suspect that while practical norms differ between communities, the underlying values of what it means to prove something are relatively consistent across mathematical communities. For example, a value held by most communities engaged with mathematical proof is that a proof should have explanatory power. What constitutes the best way to explain differs between communities. When presented with arguments during a classroom discussion about why the sum of two odd numbers is even, a group of pre-service teachers valued a well-explained empirical example over a valid deductive argument (Morris, 2007). The empirical example gave evidence that the student author was attending to the general nature of the argument by referring to making pairs, leftover pieces, and fitting the leftover pieces together to form a new pair. We suspect that many mathematicians would find a deductive argument more helpful in explaining that mathematical claim. The two communities may adopt different norms to uphold the same underlying value that proofs should explain. Even subtle changes to setting such as having a different instructor or sitting next to a different classmate can influence the norms a student chooses to adopt in proof construction.

Theoretical Framework

Two theoretical frameworks underpin this study: the zone of proximal development (Vygotsky, 1987) and motivation theory (Dweck & Leggett, 1988). The zone of proximal development (ZPD) describes the interplay between intra-psychological and inter-psychological domains that enables the emergence of more advanced cognitive activity. A common interpretation of ZPD is the interplay between what an individual can do on their own and what they can do with the help of a more knowledgeable other, thus locating the content and form of

productive instruction. Vygotsky also described ZPD as the dynamic interplay between spontaneous concepts and scientific concepts.

A *spontaneous concept* develops through everyday experience, usually without the aid of formal instruction (Vygotsky, 1987). Ideas within a spontaneous concept are specific and often lack generalization. For example, a child learning their native language is developing a spontaneous concept because the child knows many specific words but may not be able to generalize about categories such as "noun" or "fruit" through direct interaction with the associated objects, properties, effects, etc. Ideas within a spontaneous concept are specific and lack conscious awareness, volitional control, and generalization. Even if a student entering an ITP course has never been introduced to formal proof, they likely have significant spontaneous conceptions of what it means to prove a statement based on everyday interpretations of inference and justification. While these spontaneous conceptions may proport the same purpose of proof, they are likely inadequate to fully equip students to comprehend or construct valid mathematical proofs. A student's spontaneous conception of proof provides important grounding to their emerging scientific conception of proof. That is, as students learn the nuanced rhetoric of mathematical proof, their spontaneous conception of proof grounds them in the purpose of the practice, which is to explain, justify, convince, etc.

Scientific concepts are those learned through mediated interaction with their meanings (e.g. instruction; Vygotsky, 1987). They are more general and systematized but lack the accessibility and applicability of spontaneous concepts. For example, a child learning a second language is developing a scientific concept because the child is usually first introduced to general ideas like "verbs" or "clothing items" and then learns a list of vocabulary words that fall into each category. The child's verbalizations in the second language will be calculated and deliberate. As a student continuously engages in an ITP course, they will develop a scientific conception of proof that equips them with structures and vocabulary to comprehend and construct mathematical proof, even if it is initially experienced as abstract and disconnected from mathematical concepts they understand more conceptually. As students begin to develop a scientific conception of proof, they may necessarily focus on details and lose track of purposes of proof such as understanding or explaining. Spontaneous conceptions are the foundation upon which students may link their scientific conceptions of proof to meaningful ideas and ways of reasoning as they engage in course material and experience formal instruction about mathematical proof. Conversely, scientific concepts enable students to give structure to and generalize their spontaneous conceptions.

As the student develops both spontaneous and scientific concepts, the complementary strengths of each support the development of the other: scientific concepts become grounded and spontaneous concepts become refined. Initially, a student's spontaneous conception of proof may rely on the principles of proving things in familiar settings such as being provided an explanation by a parent or convincing a friend. This conception may also be shaped by some early school instruction, as when justifying an answer to a classmate or explaining a solution to a teacher, possibly with implicit or explicit feedback about what constitutes an acceptable product. As the student develops a scientific conception of proof by learning about logical structures, they will become more proficient constructing arguments to convince, justify, or explain what they constructed when they had only a spontaneous conception of proof. As the student participates in formal instruction and develops their scientific conception of proof, they may reach roadblocks where instruction is not compatible with their spontaneous conception of proof. In these

moments of incongruence, the student must adjust their spontaneous or scientific conceptions of proof.

An important component of a students' conception of mathematical proof is their belief about the purpose proof fulfills. Hanna suggested eight purposes a proof may fulfill, including verification and explanation (2000). Students' spontaneous conceptions of mathematical proof include the purposes they believe their own proofs fulfill while scientific conceptions include the purposes they are told a proof may fulfill. Once again, it is the interplay between these two conceptions that supports the development of operational conceptions of proof consistent with the mathematical community. For example, a student may be instructed that proofs can verify the truth of a statement. After writing a proof on a homework assignment the student may reflect on the argument they have constructed and recognize they have proved participated in the verification of a statement.

The goals students set during a mathematics course influence the types of activities they engage in and, consequently, the conceptions of proof they develop. Intelligence theory and goal orientation have been used to investigate the nature of student goals in mathematics classrooms (Dweck & Leggett, 1988). Dweck and Leggett distinguished between performance goals and learning goals. Individuals who adopt performance goals in a particular context are concerned with maintaining or gaining favorable judgements of ability, often from external sources. This may lead them to avoid challenging problems, which is typically seen as a maladaptive behavior since many worthwhile pursuits in both academic and non-academic life come only after confronting and resolving a challenge. Individuals who adopt learning goals in a particular context are concerned with increasing their ability. Individuals may adopt different types of goals when they are in different settings or learning different subjects. Selection of performance and learning goals are sensitive to outside factors such as task difficulty and task consistency (Steele-Johnson et al., 2000). In this study we consider student goal orientation in the context of mathematics courses with task difficulty and content consistent with that required by the course. A student's goal orientation is influenced by motivation, personality, willingness to persist through challenges, and personal beliefs about intelligence (Dweck & Leggett, 1988). Students who believe intelligence to be a fixed entity (sometimes referred to as having a fixed mindset) are prone to adopt performance goals; students who view intelligence as malleable (sometimes referred to as having a growth mindset) are prone to adopt learning goals.

A student's goal orientation, mindset about intelligence, and mathematical experience have the potential to reflexively influence one another. When a student with a growth mindset and learning goals is confronted with a challenging task, they may persevere, believing themselves capable of learning what is necessary to successfully complete the task. Alternatively, a student with a fixed mindset and learning goals may interpret failure as a sign of their personal limitations. This may lead to task avoidance or other counterproductive behaviors. A student who experiences repeated public failure in a mathematics classroom may feel shame about their abilities and begin to feel that intelligence is fixed and they are incapable of performing required tasks. This belief may lead the student to set goals to perform well in front of peers or authority figures. A student who consistently experiences the thrill of problem solving may set learning goals to stretch themselves to solve new and challenging problems. This pattern may be support or be supported by a growth mindset about intelligence.

Methods

Five undergraduate students were recruited during the first week of their ITP course in Fall 2025. Data collection consisted of two activities: weekly self-reflections and periodic clinical

interviews. At the end of each week, students completed a brief self-reflection via Google Forms about their goals, beliefs, and engagement behaviors in the course. The primary purpose of the reflections was to inform clinical interviews. The interviewer reviewed weekly reflections before each interview and asked targeted questions about specific goals, beliefs, and engagement behaviors mentioned in the reflections. For example, if a student's reflection mentioned a helpful engagement activity (e.g. taking notes in class), the interviewer asked the student to elaborate on the activity and its benefits during the interview.

The primary source of data collection was clinical interviews occurring at weeks 1, 4, 7, 12, and 16 of the semester. Phillip only participated in the first three interviews; we do not know whether he dropped the course at that time or simply withdrew participation in the study. Luke withdrew from the course between the third and fourth interview; he participated in an exit interview discussing his experience in the class and reasons for withdrawal. During each interview, students were asked to describe their current goals and ways they engaged with the class and material to achieve those goals. Students were also asked to construct at least one proof in each interview and to describe what elements of their constructed argument constituted a proof (or not). These conditions provided insight into how students define and evaluate proof. The research team then developed models of the scientific and spontaneous conceptions of mathematical proof for each student to be tested by subsequent data collection and analysis.

Interviews were transcribed and underwent open, axial, and selective coding (Corbin & Strauss, 1990). The research team conducted open coding on all five of Vivian's interviews. These initial codes were organized into categories and subcategories during axial coding, which lead to a second draft of initial codes. This codebook was then applied to other students' interviews. We employed a constant comparison method to ensure any adjustments to the codebook were retroactively applied to interviews that had already been coded. Codes were condensed and expanded to adequately represent students' experiences. Summaries describing the evolution of each student's goals and beliefs about mathematical proof were written and underwent selective coding to identify themes that persisted across multiple students. Coding occurred across three main categories: (1) the goals students expressed explicitly and implicitly, (2) students' beliefs about mathematics and proof, including their conception of mathematical proof and its purpose, and (3) the ways students engaged in the course.

Results

Goal Orientation and its Interaction with Learning Proof

Data from the first interview suggest most student participants set learning goals for the semester. For example, Luke said:

> I think approaching it initially it was more so just get an A because it's not relevant to my major, but I find it really interesting so far. So I think my opinion on that's going to change. I'd rather understand the subject at the—at its level.

We infer that Luke's proclivity to set learning goals was motivated by his newfound interest in the subject. Some students continued to express primarily learning goals throughout the semester. For example, in the fourth interview (Week 12) Max said he may not be able to achieve the high A he was hoping for, but believed it was "still very possible to like still understand everything if I go back and review everything that like I got wrong and stuff like that." We infer that Max was still orienting his behavior with the intention of learning all the material in the course. Other students, like Vivian, adopted performance goals as the semester progressed. External pressures of GPA, extracurricular activities, and parental expectations

influenced her shift to focus primarily on getting a particular grade on her transcript. In the third interview (Week 7) she said, "But I can't get a good grade without actually learning and taking something away from the course. So they go hand in hand. But to me, I just want a good letter grade on my transcript." Vivian recognized that learning would enable her to perform at a higher level, but at the time of the third interview she prioritized performance over learning.

Phillip was one of the few students who expressed primarily performance goals during the first interview and beyond. Students operating with learning goals engaged with proof in different ways than students operating with performance goals. For example, Phillip was a senior mathematics major who perceived his future career plans did not involve interacting with mathematical proofs. Of his ITP course he said it was "going to not benefit me with anything I want to go do. This is just one of the classes. I'm just trying to get—just slide by in the class." We infer he saw little value in learning proofs and repeatedly emphasized throughout his three interviews that his main goal was to pass the class and move on. By the time of his second interview Phillip was becoming more confident in his ability to construct proof but claimed he still didn't understand them. He said:

> I can go do those types of problems. Like, I know how to do them. It just doesn't make sense. But like, I'm not sitting there questioning myself if it's right or if it's wrong. I just know that it's right.

We infer that by the second interview he was developing a scientific conception of proof that included some procedural skills about how to construct a proof and that his spontaneous logical reasoning was not yet compatible with his new scientific conception. During Interview 2 there seemed to be a disconnect between his scientific and spontaneous conception of logical argumentation. In the third interview he said, "Yeah, like these ones and all like the, we started doing the uniqueness and existence. Those ones I was able to do really well too, I felt like. Those ones started to make a lot more sense." We infer that some of his scientific and spontaneous reasoning about logic were beginning to interact in productive ways, particularly in the context of writing uniqueness and existence proofs. When talking about proofs presented by the instructor during class, Phillip said, "I don't think I'll ever understand it." We infer that Phillip had a fixed mindset about learning mathematical proof.

Vivian began the semester with primarily learning goals about implementing her mathematical knowledge in the context of proof writing and building a strong foundation for future mathematics classes. However, as the semester progressed her goals seemed to shift to primarily performance goals. Vivian used artificial intelligence to help her on her homework. In the first interview she said she had recognized her tendency to give up on problems too early. She set a goal to not rely heavily on AI. In each interview Vivian discussed how she was using AI to supplement her learning in class. For example, she requested AI generate a practice exam for her based on the exam review guide provided by the instructor, used a proof generated by AI as an outline for a proof on her homework assignment, and asked AI which proof technique would be best for a particular statement. We do not believe the use of AI is necessarily maladaptive but note that many of the activities AI completed for Vivian precluded her from engaging in and thus potentially further developing strategic knowledge about mathematical proof (Weber, 2001). Perhaps in the case of Vivian, the use of AI was a maladaptive behavior engaged in with the hope that it would improve her performance in the class.

The Purpose of Mathematical Proof

In this section we focus on how students' beliefs about the purpose of proof, as described by Hanna (2000), emerged in the interviews. Students had differing views about the purpose of

mathematical proof in general and the purpose of mathematical proofs they produced themselves. For some students, the purpose of proof in general was believed to be the same as proofs generated by students, which we interpret as scientific conceptions about the purpose of proof being grounded in spontaneous conceptions; other students saw the activity they engaged in as distinct in purpose from the activity of proving in general, which we interpret as discordance between scientific and spontaneous conceptions of the purpose of proof. Phillip saw two primary purposes of proof: verify a statement is true and explain why it is true. He gave evidence that he believed these to be the purposes for both the proofs he constructed and proofs in general. Max, however, seemed to view the purpose of proof in general to be different from the primary purpose of proofs he constructed. In four interviews he made statements indicating he believed the purpose of proof in general to be explanatory; in two interviews he made claims that in general a proof should verify the truth of a statement. In three interviews, he expressed that the purpose of proofs he wrote was primarily to practice proof writing skills. In his final interview he said:

> I think it's just like good practice exercise. Other than that, I can't really think of much else just because I feel like it's very like specific thing and can't really think of a time where I would like use this fact really.

We infer that he sees the proof writing activity he engaged in as useful primarily for pedagogical purposes and not helpful in other contexts. In his final interview he included verification and explanation as additional purposes his proofs could fulfill.

Students differed in the number of distinct purposes they believed proof could fulfill. Max saw proof as potentially fulfilling three purposes (verification, explanation, and practice); Chase saw proof as potentially fulfilling seven purposes (verification, explanation, convincing, systematization, discovery, practice, and assessment). Chase saw proof in general and proofs he generated as potentially fulfilling each of these seven purposes, with the exception of assessment (only applied to student-generated proofs) and discovery (only applied to proof in general). We infer his scientific conceptions of the purpose of proof are grounded in corresponding spontaneous conceptions. Chase noted that not all proofs fulfilled the same purpose. For example, in the second interview he constructed a proof about the solution to a particular rational function then discussed what purpose the proof might fulfill. He said, "Like the core math idea it's trying to prove it's, because it's just algebra, because I've done it before a whole bunch of times, I already understand it. So it doesn't help me understand." He was then asked to construct a proof about set containment. Again the interviewer asked him what purpose the proof might fulfill. He said:

> I think it is different than the other one because, I mean, prior to this class, I hadn't really done anything with sets, so it is helpful to understand. It is helpful to understand how, I guess, maybe the properties of sets work?

We infer that Chase differentiated between the purpose of two different proofs and noticed that different proofs contribute different benefits to an author or a reader.

Discussion

Goal orientations were malleable throughout the semester. Most students started with primarily learning goals. Some maintained a learning goal orientation throughout the semester while others shifted to adopt more performance goals as the semester progressed. Learning goal orientations have been linked to more adaptive behaviors while performance goals have been

linked to maladaptive behaviors in learners (Dweck & Leggett, 1988). It is possible that the performance goals set by Vivian and Phillip limited their developing conceptions of proof. Phillip's desire to pass the class without feeling the need to understand the material may have led him to focus on the procedural components of proof at the beginning of the semester. Phillip's fixed mindset may also have impacted his goal orientation; he seemed to feel neither capable nor motivated to learn the content, so he focused his efforts on achieving a passing grade. He seemed to adopt some surface level aspects of proof related to language norms perhaps at the expense of trying to understand the logical nature of proof. It is not surprising that Phillip chose to focus on the new structures and techniques he was learning. Indeed, when individuals begin to learn scientific concepts they often experience a momentary decrease in their overall performance until scientific and spontaneous concepts begin to coalesce. We suggest that the interaction of spontaneous and scientific concepts may have been delayed by Phillip's goal orientation. Vivian's performance goals perhaps motivated her to turn to AI earlier in the problem-solving process than is desirable. Her focus on achieving a certain letter grade for her transcript may have influenced her to turn to AI, which she seemed to view as a readily accessible source of mathematical authority. We note that performance goals are not inherently negative, but they have been seen to be linked to maladaptive behaviors such as those adopted by Vivian and Phillip.

Student beliefs about the purpose of mathematical proof varied with some seeing proof as fulfilling only a few purposes while others viewing proof as fulfilling myriad purposes. Some students believed the purpose of student-generated proofs was distinct from the purpose of proof in general. We note that four of the five student participants saw explanation and verification as roles proof can play. Hanna viewed these two purposes of proof as fundamental and the most important for students entering the world of mathematics (2000). Explanatory proofs are of particular importance in educational settings.

> But in the classroom, the fundamental question that proof must address is surely "why?" In the educational domain, then, it is only natural to view proof first and foremost as explanation, and in consequence to value most highly those proofs which best help to explain. (p. 8)

We consider it productive that students saw proof fulfilling the two fundamental roles of proof. We also note that some students who view the proofs they construct as distinct from mathematician-generated proofs may recognize more specialized purposes of proof like discovering new results or organizing results into a system of axioms and results (Hanna, 2000). Alternatively, these students may feel they are separated from this aspect of participation the mathematical community.

Future Research

Data collection and analysis for this study is ongoing. Reflection and interview data is currently being gathered from students enrolled in an introduction to analysis course, which is typically the course taken immediately after the ITP course at the institution where the data were gathered. Two of the participants from this study are also participants in this second phase of data collection. We are investigating how goals, beliefs, and engagement patterns persist or evolve through extended study of mathematical proof and changes in instructor and content.

Most students talked about using AI in many ways to support their learning of mathematical proof even though the interviewer did not ask targeted questions about AI. From the perspective of the research team, some of the AI usage could have promoted productive ways of thinking about mathematical proof while others may have limited students' understanding and learning

about mathematical proof. We anticipate the availability and use of AI by students in proof-based mathematics courses to significantly increase and evolve in nature throughout the coming years. Future research could investigate ways students use AI in the learning of proof, their motives for using AI, and the perceived affordances and drawbacks. Researchers could also investigate instructors' views of AI use in proof centered mathematics classes.

AN ECOLOGICAL SYSTEMS THEORY PERSPECTIVE ON HOME MATHEMATICS ENVIRONMENT AND YOUNG CHILDREN'S FUNDS OF IDENTITY

Dawn M. Woods
Oakland University
dawnwoods@oakland.edu

Fei Xu
Oakland University
feixu@oakland.edu

As we strive to understand how young children develop productive mathematical identities, we turn to ecological systems theory to understand the nuances of family mathematics engagement. Within this framework, little is known about the lens that children and their families use to define mathematics and how this may connect to their funds of identity. Therefore, the purpose of this interpretive instrumental case study is to understand how first-grade children and their families define mathematics by analyzing the products produced as part of a Math Strong Project and then determine whether and how these lenses connect to funds of identity.

Keywords: Early Childhood Education, Identity, Ecological Systems Theory

Research suggests that children's abilities to count (i.e., sequence, one-to-one correspondence, cardinality), recognize and understand values associated with written numbers, and compare and order numbers predict concurrent and later mathematics achievement (e.g., Amland et al., 2025; Devlin et al., 2022; Lau et al., 2021; Liu et al., 2025; Wilkins et al., 2021). Research also has identified facets of the home environment and family interactions that are associated with mathematics learning. This includes the types of activities that families engage children in early math learning (Blevins-Knabe, 2016; Elliott & Bachman, 2018a, 2018b; Sonnenschein & Dowling, 2019), their mathematics beliefs and attitudes (Elliott & Bachman, 2018a; Levine et al., 2019), and their school involvement and support for learning related to children's math outcomes (Blevins-Knabe, 2016; Sonnernschein & Dowling, 2019). Yet, little is known about the lens that children and their families use to define mathematics and how this may connect to their funds of identity (i.e., the bodies of knowledge, skills, and resources that one generates through their interactions with others and their environment; Esteban-Guitart, 2016; Esteban-Guitart & Moll, 2014). Therefore, the purpose of this interpretive instrumental case study (Stake, 1995) is to understand how first-grade children and their families define mathematics by analyzing the products produced as part of a *Math Strong Project* and then determine whether and how these lenses connect to funds of identity.

Theoretical Framework

Defining Mathematics in Mathematics Education

Defining mathematics is not an easy task, and because of this, there is an ongoing debate in the field of mathematics education. To clarify this construct, we draw upon Thanheiser's (2023) work using framing (Lakoff, 2006; Louie, 2017) to explore three frames of mathematics and the implications of each frame. The three frames are as follows: (a) mathematics is an abstract body of knowledge organized into systems and structures, (b) mathematics is contextual and helps us to make sense of the world, and (c) mathematics is a human activity and part of one's identity.

Mathematics is an abstract body of language. The first frame considers mathematics as a noun. Oxford Languages (2026) defines mathematics as the science of number, quantity, and space. While others (Steen, 1988) argue that the growth of computing, statistical science, core mathematics, and applied mathematics has broadened the relationship between mathematics and science so that mathematics is not just the study of number, quantity, and space, but also has

become the science of patterns. Within the context of K-12 mathematics education, mathematics is simply viewed as a list of national standards (e.g., National Governors Association, 2010) where school mathematics becomes a space to learn about abstract rules and procedures (Adiredja, 2019). Yet, research suggests that transferring abstract knowledge of mathematics from school to the real world is difficult for children (Boaler, 1993) and adults (Lave, 1988).

Mathematics is contextual. Ascher and D'Ambrosio (1994) note that mathematics grew out of context through abstraction. In other words, mathematics is contextual. Critical scholars such as Freire (1970, 1994) and Gutstein (2006) note the differences between reading the word and reading the world. In the field of mathematics, this means mathematics can transcend procedural and conceptual understanding and be used to understand power relationships, inequities, and disparate opportunities between different social groups. Specifically, mathematics can be used to "dissect and deconstruct media and other forms of representation" in order to understand the world (Gutstein, 2006, p. 26). Further, Ani (2021) states that mathematics "isn't some arbitrary collection of skills to memorize. It is a prism for looking at the world, for analyzing how it works and reimagining how it could" (p. 11). In other words, mathematics is more than a collection of skills; it is a way of thinking.

Mathematics is a human activity. The final frame considers mathematics as a verb or action, thereby positioning mathematics as something people *do* rather than something people discover (Gutiérrez, 2018). Because of this, mathematics is more than an abstract body of language because, at its core, mathematics is a human activity and part of one's identity. Scholars (e.g., Aguirre et al., 2013, 2024; Cheng, 2022; Martin, 2009; National Research Council [NRC], 2001; Woods, 2023) define mathematical identity as how one sees themselves as a doer of mathematics. This means that children need to have opportunities to learn mathematics "in light of who they are and the diverse gifts that they bring to their experiences every day" (Aguirre et al., 2013, p. 10). To do this, teachers must work with children to become authors of their own mathematical understanding in ways that transcend procedural and conceptual understanding so that they are empowered to change the course of their lives.

So what? Recall that literature has identified that frequency and types of activities (e.g., Sonnenschein & Dowling, 2019), families' beliefs and attitudes towards mathematics and use of mathematical language are contributors to early mathematics achievement (Levine et al., 2019). Further, these three frames of mathematics may define the activities, attitudes, and use of mathematical language in home mathematics environments. Because of this, we wonder how children and their families think about mathematics in their daily lives. To guide us in our investigation, we turn to Bronfenbrenner's (1977, 1979) ecological framework to consider how humans are impacted by the changing environments in which they live and grow.

Conceptual Framework for Family Mathematics Engagement

In his work, Bronfenbrenner (1977, 1979) argues that the ecology of human development is a nested arrangement of structures describing the environment in which one lives. These structures are the microsystem (direct environment), mesosystem (connections), exosystem (indirect environment), macrosystem (culture), and chronosystem (time). These five interconnected structures shape one's growth and development. When considering the *home mathematics environment* (HME) or the role of families in early mathematics learning, scholars have used this ecological system framework to identify and assess potential moderators of mathematics learning and development (e.g., Hart et al., 2016).

Building upon the HME work, Eason and colleagues (2022) expanded the conceptual ecological framework for family mathematics engagement by combining the Integrative Model

for the Study of Developmental Competencies in Minority Children (García Coll et al., 1996), Cultural Microsystem Model (Vélez-Agosto et al., 2017), and the concept of M(ai)crosystem (Rogers et al., 2021). The intent of this new framework was to show the integration of "family, community, and societal factors that characterize children's math[ematics] experiences to provide a more comprehensive, developmental picture" (p. 4).

In our work, we leverage Eason and colleagues' (2022) framework and consider how funds of identity (FoI: i.e., a person's resources or tools that have been historically accumulated, culturally developed for self-definition, self-expression, and self-understanding; Esteban-Guitart, 2016) fit within the ecology of human development (see Figure 1). We argue that FoI allows us to contextualize how prior knowledge, experiences, and agents in and out of school may impact mathematical identity development. This framework also highlights how the three frames of mathematics may impact the breadth and depth of mathematics learning for young children.

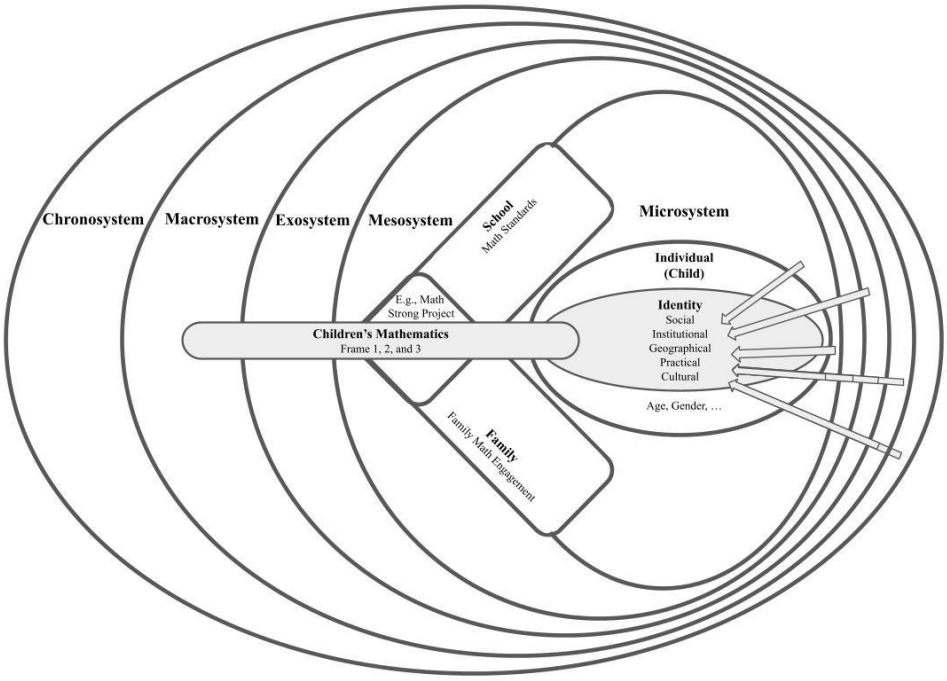

Figure 1: Funds of Mathematical Identity within an Expanded Conceptual Framework for Family Mathematics

To understand children's HME, specifically the lenses that children and their families use to define mathematics, and how this lens may connect to FoI, this study investigates two research questions. First, how do first-grade children and their families define mathematics? Second, how do these lenses connect to funds of identity?

Methods

This study was situated in a five-year longitudinal participatory research project (Vaughn & Jacquez, 2020) following kindergarten through third-grade children to understand how mathematical identity development changed over time as they participated in number talks (i.e., ten-to-fifteen-minute math discussions where children mentally solve mathematics problems and then come together as a class to share their mathematical reasoning; Parrish, 2010/2014). During

the second year of the project, our work was in first-grade classrooms, and we wondered how families defined mathematics and how it related to their child's identity development. As part of this work, teachers designed a family project to understand how families integrated mathematics into daily lives and then leveraged this to design number talks with an eye on mathematical identity development. To understand the family projects collected, we adopted an interpretative instrumental case study design to serve as a tool to guide us in understanding the relationships between families' lenses of mathematics and children's/families' FoI, rather than understanding individual children and families (Stake, 1995). This study design allowed us to obtain a more well-rounded sense of how mathematics was connected to lived experiences outside of school. Grounding this study within the literature helped us to develop a trustworthy interpretation as we collected a variety of data (triangulation), ensured adequate time in collecting data (adequate engagement), and shared findings with participants (member checks) (Stark, 2020).

Participants and Study Context

The setting was at Green Elementary School, situated in a large, public, suburban district in the Midwest. Two certified teachers, Ms. Roberts and Ms. Collins, participated in this study. (The school and participants have been provided with pseudonyms.) Ms. Roberts had 36 years of teaching experience in kindergarten and first grade, while Ms. Collins had 15 years in fifth/sixth grade and four years in first grade. Along with the two teachers, 37 (out of 43) young children who returned parent permission forms were included in the study. Among the 37 participating children, boys slightly outnumbered girls (56.8% vs. 43.2%) and most ethnicities were not Hispanic or Latino (91.9%). White constituted the largest racial group at 81.1%, followed by Native Hawaiian or Other Pacific Islander at 13.5%, and Black or African American at 5.4%. Regarding home languages, 83.8% of children spoke English, 5.4% spoke Spanish, and 10.8% spoke other languages (including Chinese, Telugu, Arabic, Albanian). For special education services, 13.5% of children had Speech Individualized Education Programs, and 5.4% had Section 504 plans.

Data Collection

One source of data was collected and analyzed in this study: *Math Strong Projects*. The goal of the *Math Strong Project* was to make a connection to children's families and the communities in which they live. We wanted to find connections between the microsystem, mesosystem, ecosystem, and macrosystems. Families had two choices in how they could participate in the project. Their first choice was an interview project where the child could interview a family or community member about how they used mathematics in their daily lives (e.g., Yeh et al., 2024). The second choice was to take a math walk around their neighborhood and take photographs or video about their mathematical discoveries (Woods, 2026). Since children and their families had the freedom to choose which activity to partake in, 13 families conducted interviews, while 24 undertook Math Walks.

Analysis

Analysis began with the authors annotating the videos and photographs collected from the *Math Strong Project* to familiarize themselves with the data (Miles et al., 2014). During the annotation process, we observed that different individuals held varying definitions of mathematics, and after turning to literature on the definitions of mathematics in mathematics education, we adopted the three frames of mathematics proposed by Thanheiser (2023) as a coding framework. During the first round, we generated open codes for systems and structures highlighted in the projects; generated open codes to identify real-world elements; and coded the five categories of FoI. As we reflected on the first round of coding these data, we turned to

literature to better understand the codes, connections to literature, and ultimately the data. To better understand Frame 1, we realized that we needed to include K-6 mathematics concepts (e.g., National Governors Association, 2010) since family members brought a sophisticated lens to the procedural and conceptual knowledge of mathematics. To better understand Frame 2, we considered if the contexts presented in the projects were purely observing mathematics or used mathematics to think critically about the world in daily life (Ani, 2021; Freire, 1970, 1994; Gutstein, 2006). In addition to coding the five categories of FoI (Esteban-Guitart, 2016), we coded if mathematics was portrayed as a noun or a verb. Table 1 explains the coding scheme, including examples from the data corpus.

Table 1: Codes, Descriptions, and Examples of Three Frames of Mathematics

Code	Brief Description	Examples
Frame 1: Mathematics is an abstract body of knowledge organized into systems and structures (e.g., National Governors Association, 2010; Thanheiser, 2023).		
Counting & Cardinality	Know number names, count sequence, and cardinality.	A child silently points and counts a total of 64 ducks on the lake.
Operations & Algebraic Thinking	Understand and use four operations, including their properties, relationships, and patterns, to represent and solve problems.	A child uses leaves and branches to represent the equation $2 + 4 = 6$.
Number & Operations	Read, write, understand, compare, and perform operations with whole numbers, rational numbers, decimals, and fractions.	A mom described how said she teaches fifth-grade children about fractions.
Measurement & Data	Describe, compare, and use measurement and estimation of different attributes in various units to solve problems. Also, represent and use data.	A child uses the words "bigger and smaller" to describe two seashells.
Geometry	Identify, describe, analyze, compare, create, compose, and classify shapes based on their attributes and properties. Solve real-world problems.	A child states that he saw a square window with four sides in the picture.
Ratios & Proportional Relationships	Understand ratio concepts and use ratio reasoning to solve problems.	A mom explains how she used mathematics to figure out percentages.
Frame 2: Mathematics is contextual and helps us to make sense of the world (Ani, 2021; Thanheiser, 2023).		
Looking At Mathematics	Mathematics as an object of observation.	A child counts the number of mailboxes on her street.
Looking With Mathematics	Mathematics is a lens for thinking critically about the world.	No examples from our data.
Frame 3: Mathematics is a human activity and part of one's identity (e.g., Esteban-Guitart, 2016; Esteban-Guitart et al., 2023; Gutiérrez, 2018; Thanheiser, 2023).		

Noun	Math is something that people discover.	A photo of 6 swings.
Verb	Math is something people do.	A child showing the number of leaves on his fingers.
Social	People who are important in one's lived experience (e.g., friends, family members).	A mom helping her child estimate and then measure the weight of a bag of sweet potatoes.
Institutional	Structures and mechanisms of society that manage behavior within a community or group (e.g., school, religion, laws).	A photo of a stop sign.
Geographical	Places and landscapes of people environments (e.g., community)	A photo of play structures inside a park.
Practical	Significant activities, interests, or hobbies (e.g., sports, exercise, work, shopping, cooking, music).	A mom explaining how she doubled a recipe to cook a favorite recipe.
Cultural	Symbols, tools, social categories that characterize, define, and mediate human experience, including money, time, religious symbols/beliefs (e.g., cross, Christmas tree), gender (e.g., hair, earrings, necklace), pop-culture (e.g., Halloween, superhero, rainbows), and technology (e.g., smartphone).	A child counting all the Halloween decorations in the yard.

Findings

Across these data, we realized that each *Math Strong Project* represented interconnected relationships between families' lenses of mathematics, providing insight into the ecological perspective of the HME. In what follows, we describe how first-grade children and their families define mathematics and how these lenses connect to funds of identity based on the descriptive statistics presented in Table 2.

Frame 1: Mathematics is an Abstract Body of Language

Frame 1 provided insight into our first research question, which is how do first-grade children and their families define mathematics. During the analysis, we realized that families prioritized mathematical concepts connected to school mathematics. Across the data, we found that the *Math Strong Projects* related to Counting and Cardinality (about 90%), followed by Measurement and Data (around 75%), Geometry (over 60%), and Operations and Algebraic Thinking (almost 60%). In contrast, Number and Operations, as well as Ratios and Proportional Relationships, were rarely presented (both lower than 10%). While the lack of Ratios and Proportional Relationships was expected since it was part of sixth-grade mathematics standards, we were surprised by the small presence of Number and Operations. We realized that this could be because it was difficult to capture place value understanding within a photograph or video, as well as limited exposure to fraction concepts.

Frame 2: Mathematics is Contextual

Analysis connected to Frame 2 also provided insight into how first-grade children and their families defined mathematics. In this data, we found that every project was situated within a real-

world context (i.e., home, park, grocery store, at work). Yet, 0% of the participants presented mathematics as a lens for critically examining the world. We found that mathematics was primarily practiced by families to address microsystem-level issues, such as supporting parents' work needs of pricing goods and managing systems. However, the findings indicated that mathematics had not yet been employed by families to understand macrosystem-level issues, such as understanding power relationships, inequities, and disparate opportunities faced by different social groups.

Table 2: Child-Level Percentages of Codes' Presentation in Interview, Math Walk, and Combined Works (the Whole Math Strong Project)

Codes by Frame	In Interview	In Math Walk	In Total
Frame 1			
Counting & Cardinality	76.9%	95.8%	89.2%
Operations & Algebraic Thinking	76.9%	50.0%	59.5%
Number & Operations	23.1%	0.0%	8.1%
Measurement & Data	76.9%	75.0%	75.7%
Geometry	30.8%	79.2%	62.2%
Ratios & Proportional Relationships	7.7%	0.0%	2.7%
Frame 2			
Looking At Mathematics	100.0%	100.0%	100.0%
Looking With Mathematics	0.0%	0.0%	0.0%
Frame 3			
Mathematics Portrayed as Noun	84.6%	29.2%	48.6%
Mathematics Portrayed as Verb	15.4%	70.8%	51.4%
Social	100.0%	54.2%	70.3%
Institutional	0.0%	12.5%	8.1%
Geographical	100.0%	87.5%	91.9%
Practical	0.0%	20.8%	13.5%
Cultural	15.4%	54.2%	40.5%
Social	100.0%		100.0%
Institutional	15.4%		15.4%
Geographical	100.0%		100.0%
Practical	92.3%		92.3%
Cultural	46.2%		46.2%

Note. C represents the children and F represents other family members.

Frame 3: Mathematics is a Human Activity

Frame 3 provided insight into how first-grade families defined mathematics. Here, children and their families portrayed mathematics as a noun (i.e., something people discover) or as a verb (i.e., something people do) with roughly equal frequency. Yet, we noticed that the math walk activity provided a better opportunity for families to do mathematics together.

Also in these data, we noticed connections to children and other family members' FoI. We observed that children and their families frequently presented geographical FoI, both accounting for over 90% of cases, through scenes such as parks, courtyards, and houses. Additionally, since the *Math Strong Project* was designed to encourage family mathematics engagement, there's

also a frequent presence of social FoI via family members' interactions. The presentation rate of social FoI among family members reached 100%, while it was approximately 70% among children (partly because the identities of individuals present cannot be determined when people are not visible in the photos or videos).

Across these data, children presented their practical FoI less frequently, at only about one-seventh the rate of other family members. This may suggest that family members are great resources and create a positive environment to help children develop practical FoI. Further, this may suggest that children were still learning to connect mathematics with their own significant activities, interests, or hobbies.

Interestingly, there was a low frequency of institutional code for both children and their families. Only 8.1% for children and 15.4% for family members showed a representation of institutional FoI. This seems to be consistent across the data sent, especially when noticing that mathematics was not used as a tool to critically think about the world at the institutional/systemic level (i.e., Frame 2).

Interpretations and Implications

Scholars (Freire 1970, 1994; Gutstein, 2006) noted the difference between reading the word and reading the world. This means that mathematics should be a tool to look at the world, to analyze how it works, and then reimagine how it could be better for all (Ani, 2021). With this in mind, we turn to the two key takeaways from this study. First, this study confirms that children and families define mathematics as an abstract body of language as they prioritize procedural knowledge over conceptual understanding when doing mathematics in connection to the *Math Strong Project*. Yet, in every project, children demonstrated this understanding in connection to real-world contexts that were a part of the children's and family members' identities. Further, mathematics was portrayed as a noun (i.e., something people discover) or as a verb (i.e., something people do) with roughly equal frequency. This means that roughly 50% of the children had the opportunity to do mathematics in ways that made sense to them, and we argue that these opportunities to use real-world contexts inspired mathematical identity development.

Although there were connections to real-world contexts that were a part of children's and families' identities, we found that mathematics was used as a tool to focus on the *word*, but not as a tool for critically examining the *world*. This finding was triangulated in the low frequency of the FoI institutional code for both children and their families. As it is becoming increasingly important for families, and society at large, to use mathematics to change the course of their lives, this research helped shed light on the HME. Additionally, this research also sparked the wonder of how we can support children and their families to use mathematics as a prism for looking at the *world* in ways that can better the human experience.

A SENSEMAKING EPISTEMIC GAME: THE CASE OF HAZEL AND LAYLA AND THE LAUNDRY TASK

Afaf Bahajj
Utah State University
afaf.bahajj@usu.edu

Sindura Kularajan
Utah State University
sindura.kularajan@usu.edu

In this study, we investigated how two pre-service teachers (PSTs), Hazel and Layla, engaged in sensemaking as they explored bacterial growth through a laundry task. Particularly, drawing on the sensemaking epistemic game framework (Odden & Russ, 2018), we examined Hazel and Layla used mathematics to represent a realistic situation. To support their sensemaking game, the PSTs engaged in two sub-epistemic games, list-making and categorization, and multiple epistemic moves. Although the PSTs were not able to attain their target epistemic form within the sense making game, they were able to make progress in mathematically representing the laundry situation. We end with discussing the implications of drawing on the epistemic games and forms framework, largely used in science education, in analyzing students' mathematics as they use it to address scientific inquiries.

Keywords: Pre-Service Teachers, Epistemic Games and Forms, Epistemic Moves, Sensemaking Games

Scientific inquiries in STEM education often involve using mathematical and statistical analysis to address the problems posed. Engaging in scientific inquiry is epistemic in nature; scientific knowledge is constructed, justified, evaluated, and refined. Within the mathematics education community, this epistemic process of using mathematics to address scientific questions has been studied from a mathematical modeling perspective (e.g., Lesh & Doerr, 2003). Within this perspective, usually, addressing scientific inquiry stems from an epistemological viewpoint that addressing questions about complex real-world problems follows certain processes that turn a non-problematized situation into a situation that can be solved and described using mathematics. For example, a scientist needs to understand the situation, make simplified assumptions about the situation, formulate a mathematical model, perform mathematical and computational analysis, evaluate the results, and interpret the results in terms of the real-world situation (Anhalt & Cortez, 2016; Blum & Leiss, 2007; Niss, 2004). While this perspective has shed light on the advancement of mathematical process-based learning, it has been limited in addressing questions such as *what do learners do as they construct and refine scientific knowledge using mathematical reasoning*, where learners' actions are taken in service of knowing rather than a set of processes they follow. In light of this, in this paper, we present a case study that examines an epistemological perspective on how mathematics is used to organize scientific problems.

Empirical and Theoretical Background: Epistemic Games and Sensemaking

Epistemic forms and games provide a powerful theoretical lens for understanding how students, the players of the game, structure their knowledge as they work on a scientific inquiry. This framework was originally proposed by Collins and Ferguson (1993). An *epistemic form* is the target structure that guides the game; this is what the players aim to attain (Collins & Ferguson, 1993; Sherry & Trigg, 1996). The *epistemic game* is the set of rules, actions (or moves), and strategies employed to develop an epistemic form (Collins & Ferguson, 1993). Therefore, each epistemic game has a *target epistemic form*.

An epistemic game consists of the following features: *entry conditions, moves, transfers, constraints,* and *target epistemic form* (Collins & Ferguson, 1993; Oden & Russ, 2018). The *entry condition* is when the game starts for the player—when the player organizes sufficient background knowledge to begin the game. The *moves* are the actions that are allowed within the game to help construct the target epistemic form. For example, in the list making game—the simplest type of game and is often used early in the inquiry process (Collins & Ferguson, 1993)—the typical moves when playing the list-making game include adding, deleting, combining, splitting, or changing items on a list (Sherry & Trigg, 1996; Collins & Ferguson, 1993). Differently, in the hierarchy game—commonly referred to as *categorizing or classifying* (Collins & Ferguson, 1993)—moves include adding items to the group and defining the categories. *Constraints* are the rules that govern the game. *Transfer* is when the player changes from one game to another, upon deciding that the current game no longer supports them in attaining their target form. For instance, students might transfer from a list-making game to a categorizing game when they observe patterns or similarities amongst the listed items (Collins & Ferguson, 1993). Lastly, the *target epistemic form* is the "goal" or knowledge structure one creates by "playing" the game (Oden & Russ, 2018, p. 3). For example, in the tic-tac-toe game, the *form* consists of the game's 3×3 matrix, *constrained* by attaining three-in-a-row of the same kind, and completing each cell with *x*'s or *o*'s to attain the constrained form are the *moves* of the game (Collins & Ferguson, 1993).

Throughout the last several decades, science education research has developed frameworks for understanding how students' reason during problem solving. For instance, in physics education research, scholars have closely examined students' as they reasoned in the moment, using mathematical symbols and coordinating them with conceptual schema (Sherin, 2001). Similarly, Tuminaro & Redish (2007) showcased how their students engaged in epistemic games and forms as the students organized their equations through conceptual resources. More recent research has further articulated sensemaking as a distinct epistemic game, emphasizing students' efforts to resolve gaps in their understanding (Odden & Russ, 2018). Parallel efforts in chemistry education have adapted and extended these frameworks to examine how students engage in sensemaking during chemical problem solving (e.g., Hunter et al., 2021; Rodriguez et al., 2020). For example, Hunter et al. (2021) used a sensemaking epistemic game to show how collaborative gas law activities can prompt students to recognize gaps in understanding and build explanations together. Collectively, this literature helps us to see students' knowledge construction as an evolving complex process rather than being linear.

Odden and Russ introduced *sensemaking* game when students are trying to figure something out using their prior experiences or knowledge (Odden & Russ, 2018, p. 2). Like any epistemic game, the sensemaking game has an entry condition, constraints, moves, transfers, and a target epistemic form. For instance, when one of their students, namely Emma, *noticed a gap* in her understanding of how an electric current works. This recognition set off the sensemaking game, and that led to a sequence of moves that helped Emma with her understanding. She made a move by suggesting that current might circulate rather than be used up. Accordingly, the target form of a sensemaking game is the resolution of a gap in students' understanding, which may or may not result in a resolved explanation (Odden & Russ, 2018); the game is afforded by the moves that help the learners resolve the gap; the constraints help define the permissible rules in the sensemaking game. With this in mind, we address the following question: *How did the PSTs enter into and sustain the sensemaking game while working on the laundry task?*

Methods

Data for this exploratory analysis were drawn from a larger study that consisted of two pairs of K-8 PSTs working on twelve modeling tasks. The PSTs were recruited from a mathematics content course required for K-8 pre-service teachers at a large public university in the western United States. The participants had completed prerequisite coursework in college algebra. The sessions were held on campus and were video- and audio-recorded. The research team met with each pair for 60 to 90 minutes, for a total of ten sessions. The PSTs were free to conceive of the laundry task however they wanted, as it was an open-ended task. For this paper, we focus on how one pair of PSTs (pseudonyms Layla and Hazel) played the sensemaking game as they worked on the laundry task. We selected Layla and Hazel's work on the laundry task because they provided an explicit episode of reasoning that allowed us to trace their entry conditions, moves, and transfers within an epistemic games framework. The abridged version of the task is provided below in Figure 1.

> On January 10, 2023, TikTok user Allison Delperdang sparked a lively debate when she shared a video about wearing the same pajamas multiple times before washing them. Dermatologist Dr. Anthony Rossi emphasized that our cultural norms often lead to "over-washing," even though not all clothes need frequent cleaning. At the same time, wearing hygiene clothes can cause skin infections due to bacterial overgrowth in the unwashed clothes. Research indicates that bacterial loads exceeding 1000 colony-forming units per square centimeter ($\boldsymbol{CFU/cm^2}$) can pose a risk, particularly for pathogenic bacteria like Staphylococcus aureus. Develop a mathematical model for determining how long clothing can be safely worn before washing?

Figure 1: The Laundry Task (abridged version). Task description taken from Smith (2023)

Data Analysis

The data was transcribed and analyzed using MAXQDA, a qualitative data analysis software, to support the identification of PSTs' sensemaking game. The analysis proceeded in three steps. First, the first author watched the video in its entirety and documented any salient epistemic episodes. During this review of the video, characteristics of a sensemaking game were noted. For example, an entry point was first captured when Hazel stated, "I'm not sure how we're supposed to work that in[referring to the 1000 CFU/cm^2]." Hazel recognized that a quantity had been provided but did not yet see how it fit into an explanation of what was happening. This moment reflected *noticing a gap* in understanding, which Odden and Russ (2018) describe as the entry condition for the sensemaking game. Hazel articulated an explanation focused on how bacteria form and multiply and attempted to connect this process to the given quantity of 1000 CFU/cm^2. Rather than using a formula or definition to construct a model, she engaged in explanatory reasoning to make sense of how the bacteria could reach that quantity.

Next, the video was subsequently revisited through the lens of a sensemaking game framework (Odden and Russ, 2018). Like any epistemic game, the sensemaking game has an entry condition, transfer, moves, constraints, and an epistemic form. For instance, the PSTs' introduction of the parameter 100 CFU/cm^2 per day was coded as a move. This was identified as a move because it helped the PSTs make sense of how many times someone could wear their clothing before the bacterial load reached 1000 CFU/cm^2 a level that could pose a risk.

Finally, the video was revisited to identify other features of epistemic games and forms, using Collins & Ferguson's (1993) framework. For example, when the PSTs started talking about their own experience regarding laundry, this instance was coded as an entry condition, as

this was the information the PSTs knew coming into the game. Similarly, the task objectives were identified as the constraint of the game since the task required the PSTs to create a mathematical model for the scenario, governing how the game could be played.

Findings

In this section, we illustrate how the sensemaking game unfolded over time. We summarize our findings in Figure 2, which presents the entry conditions, constraints, moves, transfers, and target form of the game and serves as a roadmap for the findings that follow. We describe these elements in the order in which they emerged as they worked through the laundry task.

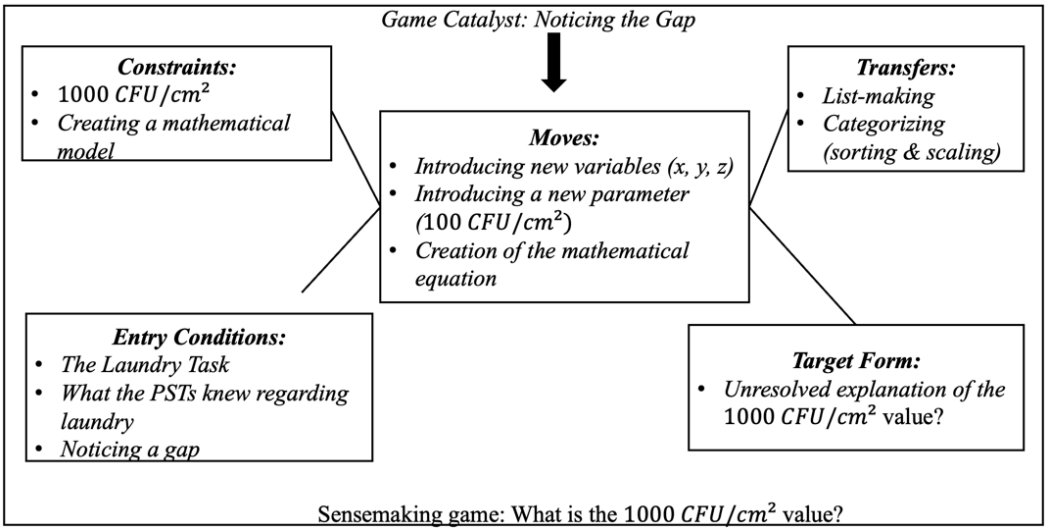

Figure 2: Overview of Hazel and Layla's Sensemaking Game

Entry Conditions

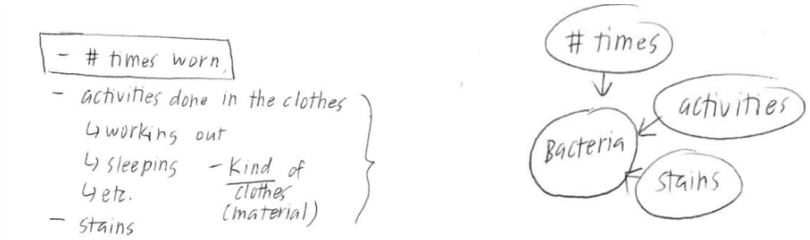
When the PSTs were given the laundry task, they started to brainstorm on how often they do their own laundry. They discussed how laundry habits vary, as it depends on factors such as clothing type and level of activity. They noted, for example, that jeans are not washed after every wear because frequent washing can cause them to wear out more quickly.

The entry condition for the sensemaking game emerged as a gap in the PSTs' understanding of how bacterial growth on clothing relates to the 1000 CFU/cm^2. As Layla and Hazel reflected on their own experiences, they referred to the statement, "Bacterial loads exceeding 1000 CFU/cm^2 can pose a risk," provided in the task. At this point, the PSTs recognized uncertainty about how bacteria accumulate on clothing and how this quantity could be incorporated into a model. They continued to discuss reasons for washing clothes; it's because of the stains on the clothes or due to hygiene. Hazel reread the prompt and still felt uncertain about how to think of bacteria growing on clothes and how to incorporate the 1000 CFU/cm^2 number into their model. Hazel says, "I'm doing my laundry… Like I've worn this three times, there's probably a lot of bacteria on here." Layla responds, "Right. Probably more than 1000 … bacteria on this person. Am I going to start thinking about that?"

Based on the conversation, we see that the PSTs drew on their prior knowledge of laundry and everyday experiences to reason about bacterial growth on their clothes.

Constraints

Within the laundry task, as the PSTs reasoned, the task was governed by rules in a few ways. First, the fixed threshold 1000 CFU/cm^2 restricted the PSTs from interpreting bacterial growth and only allowed them to work within the given threshold. This constraint shaped the allowable moves in the game as it directed attention to whether bacterial levels exceeded the stated threshold. A second constraint was the requirement that PSTs construct a mathematical model, as specified in the task. This requirement restricted how the PSTs could represent their reasoning and compelled them to translate their everyday understanding of laundry and hygiene into a mathematical model.



Moves and Transfers

We present the moves and transfers in the order in which they unfolded. As the PSTs were trying to make sense of 1000 CFU/cm^2 , the interviewer prompted them to document any ideas that came to their minds. In response, they began to create a list of reasons why they would wash their clothes. This shift marked a *transfer* from the sensemaking game to a list-making game.

List-making game [transfer]. They began to list factors that could potentially influence how frequently clothes should be washed, as shown in Figure 3: (i) the number of times worn, (ii) activities done in the clothes (e.g., working out, sleeping), (iii) stains, and (iv) the kind of clothing (material). This represents a list-making epistemic game**,** with the list serving as the epistemic form. The list-making game helped the PSTs begin making progress in their sensemaking by externalizing and organizing their ideas.

After the PSTs listed these factors shown in Figure 3a, Hazel expressed that she's having a hard time incorporating the listed items into the provided threshold of 1000 CFU/cm^2.

Hazel:	Yeah. I do wonder what it takes to get to this point, the 1000 [referring to the 1000 CFU/cm^2].
Interviewer:	What do you mean?
Hazel:	Like what sort of conditions or sort of numbers on these things [referring to the list in Figure 3a] would lead to this amount? I'm wondering if this is like you haven't washed this clothing item in months, or if this is average, like by the time you do your laundry every two weeks … causing a dangerous risk. I really have no idea, though, because I don't know anything about bacteria.

(a) (b)

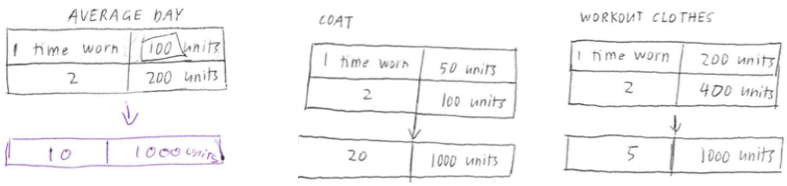
Figure 3: (a) Listing-making Game, (b) Contribution Towards Bacteria

We can observe that Hazel is still uncertain about how the 1000 CFU/cm^2 value was determined. She speculates whether it results from extreme conditions, such as not washing clothing for an extended period, or if it represents an average accumulation.

This uncertainty continues to illustrate the gap in Hazel's understanding of how bacteria accumulate, which in turn hinders her ability to progress in developing the model. At this point, the PSTs transferred back to the sensemaking game from the listing-making game. They then start making *moves*, such as introducing a new parameter and a new variable, to help with their progression of making sense of the 1000 CFU/cm^2 threshold.

Introducing a new parameter [move]. After the conversation above, Layla suggested coming up with numbers, making a move by introducing a *new parameter*, which was 100 CFU/cm^2 per day. This is a move as the PSTs wanted to understand the rate at which bacteria can be accumulated and for how long clothes could be worn to reach the 1000 CFU/cm^2 threshold. Layla wrote that on day two, it becomes 200 CFU/cm^2, on day three, it becomes 300 CFU/cm^2, and so forth. Here, for the PSTs, 100 CFU/cm^2 per day is a daily rate that, in this specific scenario, is treated as a constant parameter. They used this parameter to reason about bacterial growth, which can change over time. The PSTs reasoned that changes to the value may occur in coordination with other quantities, such as activities done on the clothing or the presence of stains.

Introducing a new variable [move]. Right after they introduced the parameter, the PSTs introduced a new variable, $\boldsymbol{x}$, to represent the number of times worn. They expressed this relationship as $\boldsymbol{x \times 100}$ *units = how many units formed on the clothing*. They reasoned that on an average day, clothing could be worn up to ten times before reaching $\boldsymbol{1000\ CFU/cm^2}$. They explained that when you wear clothes one time, you get $\boldsymbol{100\ CFU/cm^2}$, so wearing the clothes ten times would lead to $\boldsymbol{1000\ CFU/cm^2}$**.** The introduction of the variable, *x*, supported the emergence of their representation and enabled the PSTs to reason about the change in bacterial load over repeated wears.

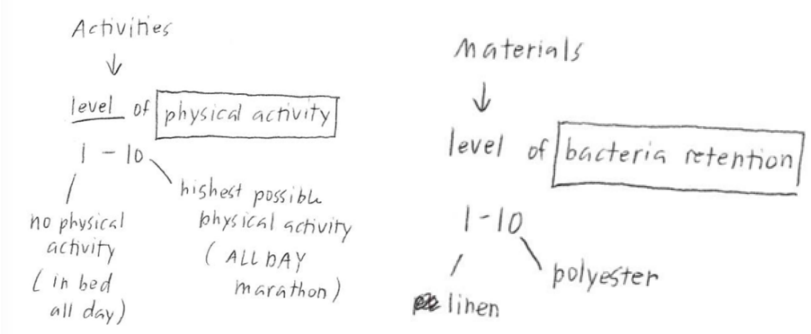


Categorizing game [transfer]. After the PSTs made the two moves of introducing a new parameter and variable, they started to reason about the dependency of bacteria accumulation on the factors listed in Figure 3a. At this moment, the students *transferred* from the sensemaking game to the categorizing game. Within the categorizing game, the PSTs employed two types of categorizations: (a) sorting and (b) scaling.

Sorting. When PSTs listed the factors that influence the number of bacteria accumulated, Hazel realized that they needed to sort out the factors they listed in Figure 3a into different categories because activities like exercising, being sick, and carrying out a normal day will all influence the growth of bacteria differently. As for Figure 3b, the PSTs drew a presentation showing that the type of activities done in the clothing, the number of times worn, and stains on the clothing all contribute towards the rate of bacteria.

Hazel said, "I mean, you could wear something for 30 minutes, while you're doing yoga, and then change out of it. I don't know how much these [referring to Figure 3b] are affecting this first table [referring to Figure 4a], because I think it's sort of a single input-output sort of situation." For the PSTs, an average day is when they are not doing anything physically demanding. The PSTs then sorted items based on similarities in how bacterial formation will occur. As shown in Figure 4(a, b) below, they sorted the amount of bacteria formed based on the activity done or the clothing type. They were sorted as an average day, workout clothes, and coats, with 100, 200, and 50 CFU/cm^2, respectively, for each wear.

Scaling. Another instance in which we observed the PSTs utilize categorizing occurred when they employed a scaling approach to organize physical activity and type of material by assigning values from 1 to 10. The idea of scaling emerged when the interviewer asked how the factors shown in Figure 3b influence the 100 CFU/cm^2. This scaling approach was proposed because it



was easier for the PSTs to interpret and apply how the activity level influences bacterial accumulation on clothing.

(a) (b)

Figure 4: PSTs' Sorting

The PSTs applied the same scaling approach to clothing material, informed by online sources. Using this scaling approach, as shown in Figure 5a, a value of 1 represented the lowest level of bacterial retention, which they associated with linen, while a value of 10 indicated the highest retention, which they attributed to polyester, as shown in Figure 5b. Hazel further explained that an "average day" may involve minimal physical activity, such as walking to class, whereas some individuals exercise once or twice a day. She therefore suggested representing physical activity using a numerical scale from 1 to 10. On this scale, a value of 1 corresponds to no movement at all (e.g., staying in bed all day), while a value of 10 represents the highest level of exertion, such as hiking or running a marathon.

(a) (b)

Figure 5: PSTs Scaling

Creation of the mathematical equation [move]. After sorting and scaling, the PSTs introduced two additional variables y and z that represented the level of physical activity and bacterial retention, respectively. They proposed the model $x = units \div (y \times z)$, where units refer to 1000 CFU/cm^2. Layla critiqued the model by testing it against an extreme but plausible scenario, noting that under the model, someone could run multiple all-day marathons in polyester without risk-posing bacterial buildup, which did not make sense to her. Hazel agreed with Layla and further emphasized her uncertainty about how quickly bacteria accumulate, stating that 1000 CFU/cm^2 seemed like a large number without a clear basis.

Target Epistemic Form

While the structure of the mathematical model created by the PSTs allowed them to reason quantitatively about clothing type, activity level, and bacterial buildup, they remained uncertain

about how the value of 1000 CFU/cm^2 was determined. Although the PSTs made progress in structuring their reasoning, their sensemaking remained unresolved. The PSTs also developed representations such as lists, categories, and a model; these artifacts reveal the ways in which students approached the problem, highlighting their reasoning processes rather than emphasizing a final correct result.

Discussion

Our findings indicate that the PSTs used multiple epistemic sub-games, namely list-making and categorizing games, to make progress in their sensemaking game. This suggests that the flexibility and fluency to transfer between epistemic sub-games support the gradual attainment of a mathematical model for the scenario, despite being unable to resolve their sensemaking of 1000 CFU/cm^2. This insight raises important questions for the field: (1) what roles do epistemic games play in students' construction of a mathematical representation for a realistic scenario? and (2) how can we design learning experiences that facilitate the emergence of epistemic games and moves among students? In our case, the list-making game helped the PSTs think about why someone would wash their clothes, leading them to identify various contributing factors. On the other hand, the categorizing game helped the PSTs organize these factors based on how bacterial accumulation depends on them. Had the PSTs already known the formation of bacteria, we might not have been able to observe the PSTs' sensemaking game; instead, what we might have observed is an "answer-making" game. Thus, we hypothesize that the tasks, learning environment, and students' prior knowledge can inform the game a student plays.

Furthermore, in an era where artificial intelligence can readily provide answers to scientific prompts, the focus of instruction should not merely depend on having students generate answers to problems. Instead, learning experiences should focus on how students can connect their past knowledge in meaningful ways to construct new knowledge (Schoenfeld, 1992). In this view, the final epistemic form that students construct becomes subordinate to the *ways in which* (i.e., epistemic moves and actions) they constructed the product. In our case, Hazel and Layla made progress in the ways they reasoned as to how bacteria can accumulate, through their epistemic actions. These actions were instrumental for them to move beyond their knowledge gap and attend to the goals of the task. Thus, educators should provide learners with opportunities to develop tools that enable students to advance their knowledge construction even in the presence of perturbations and inconsistencies, rather than abandoning the process.

We acknowledge certain limitations of our study. One key limitation is that our findings may only hold true in the case illustrated here. That is, we demonstrated the feasibility of using the epistemic forms and games framework to analyze Hazel and Layla's construction of mathematical representation for the laundry scenario. Looking through a sensemaking epistemic game lens, different students working on different tasks may yield different outcomes. Thus, while our findings are locally rich, they do not propose a principled way for documenting learners' diverse sensemaking strategies as they engage in scientific inquiry.

That said, a substantial body of research across other disciplines, such as chemistry, physics, and life sciences, have been examining how students construct knowledge (e.g., Tuminaro & Redish, 2007; Hunter et al., 2021; Rodriguez et al., 2020). Collectively, these works have resulted in robust frameworks, such as symbolic forms (Sherin, 2001) and resources (Hammer, 2000), that have been influential in analyzing students' scientific knowledge construction. For mathematics to be considered as a *vehicle* for addressing scientific inquiries, in addition to a domain of inquiry, frameworks that enable the explanation of such knowledge, such as epistemic forms and games, should be adapted and tested for feasibility. We conclude by stating that our

study contributes to this effort by showcasing the feasibility of such an approach through a detailed case example.

EXPLORING STUDENTS' PERCEPTIONS OF MATHEMATICS INSTRUCTORS AND THEIR IMPACTS ON THEIR ACHIEVEMENT

Shashidhar Belbase
Troy University
sbelbase@troy.edu

Nicholas Newman
Troy University
newman@troy.edu

This study aims to explore 8th-grade students' perceptions of mathematics instructors and their impacts on achievement in TIMSS 2015 and 2023. The publicly available TIMSS 2015 and 2023 data were used to explore students' perceptions of mathematics lessons and their achievement. The data were analyzed in IBM SPSS 29 to examine students' perceptions of mathematics instructors, using mean and standard deviation, and linear multiple regression was performed to examine the effect of these perceptions on mathematics achievement. The results showed that students had positive perceptions of their mathematics lessons in both 2015 and 2023. However, their effects on achievement were inconsistent across both years. These differences in the impact of students' perceptions of mathematics lessons on achievement indicate that other intervening variables may influence perceptions of lessons and mathematics achievement over time.

Keywords: Student Perceptions, Mathematics Lessons, Achievement, TIMSS

Students' perceptions of mathematics instructors may determine the quality of their learning and may affect their achievement. Past studies have reported that students' achievement in mathematics is influenced by a variety of contributing factors, such as teacher-related factors (Appiah et al., 2022), school factors (Chowa et al., 2015; Wardat et al., 2022), student factors (Wardat et al., 2023), and home background (Oginni, 2018; Tomul et al., 2021). Past studies also focused on students' perceptions of mathematics, mathematics learning, and their influence on achievement (Ampadu, 2012; Arthur et al., 2017; Daud et al., 2020; Hagan et al., 2020). However, there is a scarcity of literature that focuses on students' perceptions of mathematics instructors and their influence on achievement. This study is conducted to fill the gap in the literature. The objective of this study is to explore eighth-grade students' perceptions of mathematics instructors and their impacts on achievement from TIMSS 2015 and 2023 data. The research questions for the study were: How do U.S. eighth-grade students perceive their mathematics lessons, and how do these perceptions influence their achievement in TIMSS 2015 and 2023?

Materials and Methods

The data for the study were retrieved from the IEA TIMSS and PIRLS at Boston College (link: https://timssandpirls.bc.edu/index.html) for both 2015 and 2023 US data. The data is available in the public domain for research purposes. The TIMSS 2019 data were not used in this analysis because the items on students' perceptions of mathematics instructors were slightly reframed and the data was gathered during 2020, which was heavily impacted by the Covid-19 Pandemic. There are ten items for students' perceptions of mathematics. These items are given in Table 1.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Table 1: Eighth-Grade Students' Perceptions of Mathematics Lessons in TIMSS 2015 and 2023

Sl. No.	Items of students' perceptions of mathematics lessons	Agree a lot	Agree a little	Disagree a little	Disagree a lot
1	I know what my teacher expects me to do.				
2	My teacher is easy to understand.				
3	I am interested in what my teacher says.				
4	My teacher gives me interesting things to do.				
5	My teacher has clear answers to my questions.				
6	My teacher is good at explaining mathematics.				
7	My teacher lets me show what I have learned.				
8	My teacher does a variety of things to help us learn.				
9	My teacher tells me how to do better when I make a mistake.				
10	My teacher listens to what I have to say.				

The original data coded as: Agree a lot = 1, Agree a little = 2, Disagree a little = 3, and Disagree a lot = 4. This coding was reversed to assign the highest value of 4 to "Agree a lot" and the lowest value of 1 to "Disagree a lot" for easier comparison of the degree of agreement and its association with mathematics achievement. Average and standard deviations for each item for students' perceptions of mathematics were computed for both 2015 and 2023. Then, a linear multiple regression analysis was performed to examine the impact of each perceptual item on students' mathematics achievement in 2015 and 2023. TIMSS uses item response theory to construct five plausible values for student achievement. This study used only one plausible value (the first one) as the dependent variable for the regression analysis because there were no statistically significant outcomes while using all five plausible values. The ten perceptual items in Table 1 were used as independent variables. The residual analysis for the dependent variable (achievement data) indicated normality, and hence, regression analysis was deemed valid.

Results

The results of the descriptive analysis of students' perceptions of mathematics lessons in 2015 and 2023 were positive across all 10 items, with average values greater than 3 (Figure 1).

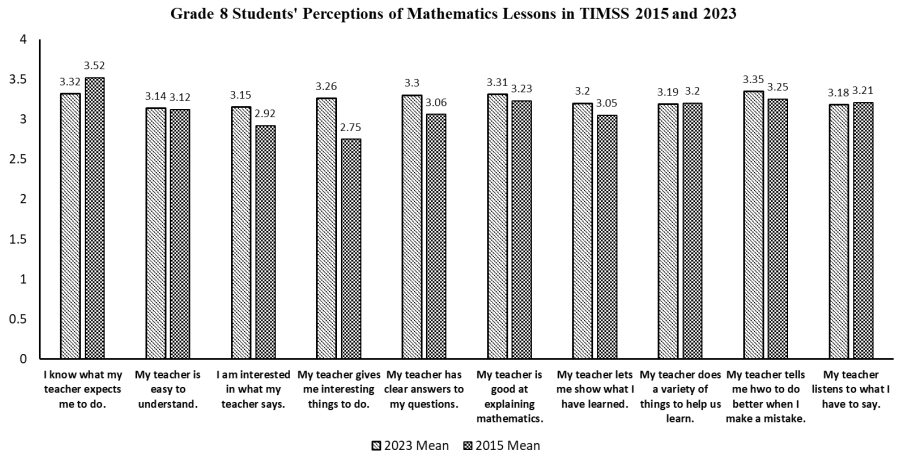

Figure 1: Eighth Grade Students' Perceptions of Mathematics Instructors in 2015 and 2023

The results of the linear multiple regression showed that students' mathematics achievement was influenced by only one item from their perceptions of mathematics lessons in 2015 and 2023. For example, "my teacher is easy to understand" with regression coefficients of 11.64 and 8.195, both statistically significant ($p < .001$). Another item, "my teacher gives me interesting things to do," had a positive influence on achievement in 2023, whereas it had a negative effect in 2015. Likewise, another item, "my teacher tells me how to do better when I make a mistake," is positively associated with achievement in 2023, whereas it was negatively associated with achievement in 2015. However, the item "my teacher lets me show what I have learned" was negatively associated with achievement in 2023, though it was positively associated in 2015. In a similar vein, the item "my teacher listens to what I have to say" shows a negative association with achievement in 2023, though it was positive in 2015 (See Table 2).

Table 2: Regression Coefficients and Their Significance for Students' Perceptions of Mathematics Lessons (Independent Variables) and Achievement (Dependent Variables)

SN.	Independent Variables	B (2023)	Sig. (2023)	B (2015)	Sig. (2015)
0	Constant	449.894	< .001	465.411	< .001
1	I know what my teacher expects me to do.	–1.402	.486	8.666	< .001
2	My teacher is easy to understand.	11.640	< .001	8.195	< .001
3	I am interested in what my teacher says.	–2.010	.347	8.329	< .001
4	My teacher gives me interesting things to do.	11.803	< .001	–7.695	< .001
5	My teacher has clear answers to my questions.	–2.396	.255	0.783	.586
6	My teacher is good at explaining mathematics.	1.289	.525	7.463	< .001
7	My teacher lets me show what I have learned.	–13.916	< .001	5.663	< .001
8	My teacher does a variety of things to help us learn.	0.684	.703	–12.679	< .001
9	My teacher tells me how to do better when I make a mistake.	14.325	< .001	–9.659	< .001
10	My teacher listens to what I have to say.	–6.206	< .001	6.627	< .001

Dependent Variable: Achievement (Plausible Value 1 for TIMSS US 20215 and 2023)
Note. Collinearity was examined using Variance Inflation Factors (VIFs), and low collinearity was observed among the independent variables (VIF < 5).

Discussion and Conclusion

Students' achievement in mathematics is affected by a variety of factors, such as school, teacher, classroom environment, family background, and students' personal perceptions of the subject, their learning of mathematics, and classroom lessons. This study examined eighth-grade students' perceptions of mathematics instructors and how these perceptions influence their mathematics achievement in the TIMSS 2015 and 2023 US. The results showed that eighth graders generally had positive perceptions of mathematics lessons in both 2015 and 2023. However, these perceptions had differing effects on mathematics achievements. Most of the items measuring perceptions of mathematics lessons show a significant association with achievement, except one item, 'my mathematics teacher has clear answers to my questions', in 2015. However, the very same perceptual items that had a significant influence on mathematics achievement in 2025 were ineffective in 2023. For example, the item "I know what my teacher expects me to do" had no statistically significant effect on achievement in 2023, though it had a significant positive effect on achievement in 2015. Similar is the case for items "I am interested in what my teacher says," "my teacher is good at explaining mathematics," and "my teacher does

a variety of things to help us learn." One possible reason for these changes is students' ability to learn mathematics more independently, supported by different technological tools in general, and their greater self-awareness and higher self-esteem in mathematics learning, rather than relying on teachers. Long school closures led to dramatic drops in math skills, making students more dependent than ever on qualified teachers for remediation. The sequential nature of math made distance learning difficult, creating compounding learning gaps that teachers had to fix upon return to the classroom. (Sattem, 2022). Further study is needed to confirm what prompted for students' independence in mathematics learning and the less impact of their perceptions of classroom instructors on achievement. One of the major limitations of the study was that only one plausible value was used for the analysis out of five plausible values for students' achievement.

STARMath (STM) is a near-peer, mathematics mentoring and tutoring program that has served hundreds of marginalized middle and high school students in the Midwestern United States over the past decade. Built on the strength and resilience of their communities, this after-school program has supported mathematics instruction and learning in several urban settings serving predominantly Black, Brown, and Asian students. Mentutors (mentor + tutor) in this program are undergraduates from the local state university, providing mathematical expertise and peer advice that sustains this community. With the goal of centering the voices of program stakeholders, this research report examines the six-word stories of mentutors from the program's inception through the present day. Findings suggest that academics, personal validation, and community are key intersections within a supportive math learning environment.

Keywords: Community-Based Praxis; Identity and Agency; Culture and Asset-Based Pedagogies; Equity, Inclusion, and Diversity

Since the 1990s, many states have responded to the national Algebra for All initiative — a program aimed at ensuring equal access to eighth-grade algebra or Algebra 1 by ninth grade (Loveless, 2008; Carolan, 2014). However, urban districts nationwide have continued to face alarming algebra failure rates over the past two decades (Loveless, 2008; Heppen et al., 2016). Given this challenge, the STARMath (STM) program integrates near-peer mathematics tutoring, community building, and family collaboration to enhance students' content knowledge in algebra and foster their mathematics self-concept (Hattie, 2014), which is critical to their future success. "Many authors consider that mathematics self-concept plays a key role in mathematics teaching and is related to the student's attitudes, mathematics world perspective and social identity" (Ansuategui & Miravet, 2017, p. 1188). As mentutors are key to the success of this program, this paper examines their six-word stories and what the STM program means to them, over the course of the program's 13 years. As a unit of analysis, the six-word story focuses our attention on mentutors' most salient thoughts and ideas, as they are restricted to brevity to tell their story.

Purpose

STM uses a unique near-peer tutoring and mentoring model that supports the study of algebra in small learning communities. Each week, middle and high school algebra students sit together with an undergraduate who is also studying a STEM (Science, Technology, Engineering, and Mathematics) discipline. The high school student tutors the middle schooler (with the supervision of the undergraduate), and then the undergraduate "mentutor" (the combined roles of mentoring and tutoring) supports the high school student with their homework and preparation for the ACT. Weekly, groups of 6–8 students gather around tables (named after underrepresented mathematicians and scientists) to work on mathematics homework and also share informal

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

conversations during a healthy meal. This intentional structure facilitates authentic conversations and opportunities for informal mentoring, interrupting and dismantling power dynamics. Moreover, this program develops a shared capacity for collective dreaming and change-making where participants share stories connected to and moving beyond their educational wellbeing. STM's primary purpose was to support the mathematics experiences and outcomes of middle and high school students in order to better position them to compete in STEM-centered academics and careers. While the impact and outcomes for the middle and high school students were anticipated, the larger project from which this data is drawn, uncovered unanticipated outcomes for the mentutors. This sub-study moves forward with the following research question in order to examine the other stakeholders in STM. "How do mentutors describe shifts in their identities as a result of participating in an urban mathematics tutoring program?"

Theoretical Framework

Because our study takes place in a social and academic mathematics learning setting (i.e. the tutoring space), and we are interested in program participants' stories they tell from within this space, we come to this work from a lens of identity formation within educational spaces. Mead (1913/2011) proposes that identity is an action situated within an interactive social environment, making it multifaceted and complex (pp. 374–380 as cited by Darragh, 2016). In education research, identity has been an essential concept as it bridges learning with the cultural and social context (e.g., Sfard & Prusak, 2005; Graven & Heyd-Metzuyanim, 2019) and provides a lens for analyzing power, access, and equity issues (Radišić et al., 2024). Sfard and Prusak (2005) name identity as a "collection of stories about persons, or more specifically, those narratives about individuals that are reifying, endorsable and significant" (p. 16). This study employs a sociocultural lens to explore how mentutors construct their social identity in mathematics through six-word stories.

Methods

This study captures the concise stories of STM mentutors and seeks to understand how their mathematics identities developed through their participation in the program. While identity as described above is a complex inner and outer sociocultural phenomenon, we argue that the six-word story, though brief in nature, provides powerful insight to the most salient themes within a person's identity, as they themself choose to tell. As an analogy, climate and nature are complex systems, but how do environmental scientists uncover clues about atmospheric conditions? The series of concentric tree rings reveals insights and narratives about human impacts on the environment (Norris, 2024). While dendrochronology examines various patterns and contours of tree rings, the six-word story methodology functions as a "social tree circle" (Norris, 2024, p. 325), revealing the patterns of participants' thoughts, emotions, and experiences, as well as their interactions with the mathematical environment and the impacts they leave behind for the future. The six-word story serves as a "living portal" that encapsulates intricate human experiences related to teaching and learning mathematics, intertwining with culture, self-identity, belonging, and more in a nuanced and succinct manner (Norris, 2024, p. 325). We capture six-word stories that span time and space, yet stories of all kinds demonstrate common patterns, and "patterns themselves tell a story" (Norris, 2024, p. 326).

Six-word stories challenge the writer to tell their story in only six words. Brevity forces the writer to choose their words carefully while capturing the totality of their thoughts. This "methodology" is used in this study in order to understand the effects of the STARMath program through short, carefully selected words forming a sentence that provides insight into the most

important and meaningful experiences from their program participation. Additionally, participants expanded on the narratives within their six-word stories by responding to a follow-up question that probed them on their word choice.

Data Sources and Evidences

Six-word stories and the story meanings were collected from current and previous mentutors from over the past 13 years. The majority of mentutors were in their first year of service to the program and were STEM or education undergraduates at the local, midwestern division one research institute. There were 21 total six-word stories collected. We were not interested in using a traditional methodology to examine the effects of a non-traditional program. Rather, we employed the six-word story as a contemporary form to investigate the phenomenon of word choice, tone, and content. In essence, this study employs a phenomenological approach to understand the impact of STM on the mentutors. Each member of the research team read the six-word stories and identified three to four themes individually that encapsulated most of the stories. The research team met to compare themes and negotiate the themes into three overarching themes. During this process, we realized that the themes overlapped for many of the six-word stories, motivating the creation of a conceptual framework that captures these themes.

Findings

We identified three themes that appeared within the six-word stories: academics, personal growth, and community. These themes were not independent and overlapped in notable ways, thus forming a conceptual framework (Figure 1) that captures the mentutors' experiences and shifts in identity that resulted from participating in STARMath. The intersection of each category offered insights into how mentutors grew and developed through this programming. The intersection of academics and personal growth produced *math confidence*. *Joy* was cultivated from the overlap of personal growth and community while academics and community was identified as a *sense of belonging*. The following discussion examines each of the intersections (subthemes) from the framework.

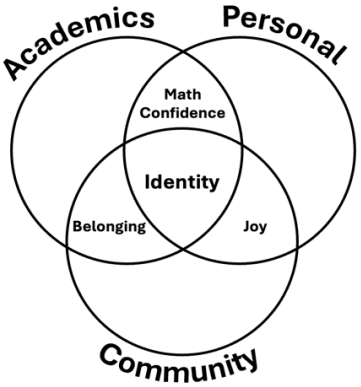

Figure 1: Conceptual Framework Showing the Intersection of Academics, Personal Growth, and Community

Mathematics Confidence: The Intersection of Academics and Personal Growth

When mentutors' descriptions of academic content and their personal development intersected, we called this *mathematics confidence*. For example, one mentutor shared, "One plus one does equal two" and further described:

> …when I was working with the high school students I was reminded about how much foundational math matters in the long scheme of things. If one does not know that 1 + 1 = 2, how can you possibly be prepared for things to get more difficult?

This mentutor described both the importance of foundational mathematics and how this basis prepared them for future challenges. This story highlights how, whether in mathematics or in life, learning is a continuum that builds on itself. This was an important lesson that students and mentutors learned from participating in the STARMath program.

Sense of Belonging: The Intersection of Academics and Community

We identified a *sense of belonging* as the intersection of academics and community. One mentutor shared, "Community empowers students and their learning" and elaborated:

> I found that being in an environment where everyone had something to learn from one another (even from the students to the tutors—whether it was about the math or it was about how to be a good listener/communicator), a strong community was built where students felt comfortable. It empowered them to be able to be themselves … which led them to a better understanding of the material.

This mentutor highlighted the reciprocal nature of the STM program. Mentutors were there to mentor and tutor high school and middle school students, however many of them found that they developed a mutual exchange of learning. By feeling a sense of shared belonging, students felt empowered to engage in both academic and social learning.

Joy: The Intersection of Personal Growth and Community

Finally, we used *joy* to describe when personal growth and community intersected. Several six-word stories indicated this shared joy, for example: "Succeeding in life—a community endeavor" and "Got me looking forward for Wednesdays." These six-word stories demonstrate the joy mentutors experienced from participating in a community environment and how these experiences positively influenced their time in the program. One mentutor described this joy:

> The support provided by [STM] did more than tutor kids … it was the sincere interest and gratitude in one another's presence. All these are easy to lose once you leave school or have to be independent, so it shines as a bright example of how to weave a community together.

Creating a program space where participants had opportunities to demonstrate this shared gratitude, allowed mentutors to grow both personally and as a community.

Discussion

STM was developed to support algebra learning for marginalized middle and high school students, who have always been the primary stakeholders of programming and research. The undergraduate and graduate students who served as mentutors were an integral part of the program delivery, and their six-word stories provide evidence of identity shifts. We found that their participation in STM contributed to shifts in their mathematical identities in ways similar to the shifts experienced by primary stakeholders. We argue that mathematics confidence, a sense of belonging, and joy were foundational to developing the identity of the mentutors in connection to the STM program. They were there to support students, but in doing so, they were helping themselves develop as a tutor, as a mentor, and as a math learner. The implications for the mentutor's role do not lie only in the content delivery and mentorship, but raises up the change in identity, levels of joy and fulfillment, and increased sense of belonging for the mentutor as well.

This study investigates student-related factors affecting interest in mathematics at the senior high school (SHS) level in Cape Coast, Ghana. Using a concurrent mixed-methods design, data were collected from 450 students and six teachers through surveys and interviews. Analysis through chi-square tests revealed no significant association between interest and gender or age, but a strong correlation with the program of study. Key drivers of interest included a willingness to exert effort and perceived real-world relevance. Current literature suggests that interest acts as a significant mediator between perception and performance. Furthermore, clear teacher explanations and adaptive pedagogies are vital for sustaining long-term engagement. By identifying these levers, the study supports the "Educating for Change," advocating for pedagogical shifts that dismantle mathematics as a gatekeeper and address systemic injustices within academic tracks.

Keywords: High School Education; Advanced Mathematical Thinking; Learning Trajectories and Progressions; Affect, Emotion, Beliefs, and Attitudes

Background to the Study

Mathematics serves as a critical gatekeeper in the global educational landscape, dictating access to advanced STEM opportunities and professional efficacy. Despite its importance, consistent underachievement remains a persistent challenge; in Ghana, pass rates for standardized mathematics examinations have shown a concerning decline, dropping from 65.3% in 2019 to 54.11% in 2021. While traditional research often focuses on external variables, current scholarship identifies student-level interest as the primary determinant of mathematics achievement. This study specifically investigates student-related factors impacting interest in mathematics at the senior high school (SHS) level within the Cape Coast Metropolis. By exploring these dynamics, the research contributes to the objective of "Changing Mathematics Education by Educating for Change" by identifying how internal student dispositions can be leveraged to overcome instructional stagnation and promote a more mathematically literate society.

Objectives and Purposes of the Study

Mathematics serves as a critical gatekeeper in the global educational landscape, dictating access to advanced STEM opportunities and professional efficacy. However, consistent underachievement remains a persistent challenge; in Ghana, pass rates for standardized mathematics examinations have shown a concerning decline, dropping from 65.3% in 2019 to 54.11% in 2021. While traditional research often focuses on external variables, current

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

scholarship identifies student-level interest as the primary determinant of mathematics achievement (Wijaya et al., 2022).

This study specifically investigates student-related factors impacting interest in mathematics at the senior high school (SHS) level within the Cape Coast Metropolis, Ghana. The research aims to address:

1. The association between students' demographic factors (gender, age, and program of study) and their interest in learning mathematics.
2. Specific student-related factors, such as self-efficacy and perceived utility, that influence interest.

By exploring these dynamics, the study contributes to the PME-NA 2026 objective of "Changing Mathematics Education by Educating for Change" by identifying how internal student dispositions can be leveraged to overcome instructional stagnation and promote a more mathematically literate society.

Perspective and Theoretical Framework

The study is grounded in cognitive constructivism, which posits that knowledge is actively constructed through pre-existing cognitive structures (GSI Teaching and Resource Centre, 2015). It also draws upon *Situated Expectancy-Value Theory (SEVT)*, suggesting that students' beliefs about their competence (expectancy) and the significance ascribed to the subject (value) are primary drivers of motivation (Eccles & Wigfield, 2002). Recent work extends this by examining the "cost" dimension—the perceived negative consequences of engagement, such as effort and ego costs.

Current research highlights that student interest partially mediates the relationship between perception of the subject and final performance, with a significant indirect effect. Furthermore, individual psychological factors such as mathematics anxiety can cause students to avoid engagement, leading to performance deficits (Ashcraft & Krause, 2007). Conversely, intrinsic motivation—derived from personal satisfaction—can elevate learners into a state of "flow" (Csikszentmihalyi, 1990). Modern frameworks like the Technological Knowledge of Algebra for Teaching (T-KAT) also suggest that teachers' ability to "unzip" content using digital tools is essential for making ideas learnable in the 21st century.

Methods and Modes of Inquiry

A concurrent mixed-methods approach was employed to provide a multidimensional analysis of student engagement.

Participants and Sampling

The target population included all public SHS students in the Cape Coast Metropolis. A multi-stage sampling procedure was used to select 450 second-year students from three co-educational schools (150 from each school). The sample represented General Science, General Arts, and Home Economics programs. Additionally, six mathematics teachers were purposively selected for semi-structured interviews.

Data Collection and Analysis

Quantitative data were gathered using a self-developed 5-point Likert scale questionnaire (reliability coefficients: $\alpha = 0.821$ for student factors; $\alpha = 0.850$ for interest). Qualitative data were collected through interviews to capture teacher perspectives. Analysis involved descriptive

statistics and chi-square tests of association (x^2) performed through SPSS version 26 at a 0.05 level of significance.

Results

The findings provide insight into the demographic and psychological barriers to mathematical interest.

Demographic Associations

Statistical analysis showed no significant association between gender and interest $x^2 = 5.150$, $p = 0.076$) or age and interest ($x^2 = 5.391$, $p = 0.495$). This contradicts traditional gender stereotypes suggested by Hyde and Mertz (2009). However, a highly significant association was found for the *program of study* ($x^2 = 34.561$, $p = 0.000$). General Science students reported the highest interest (30.89%), while Home Economics students reported the lowest (21.78%).

Student-Related Psychological Factors

The highest-rated factor was a willingness to exert effort and persevere ($M = 4.08$, $SD = 1.070$), which aligns with Bandura's (1997) construct of self-efficacy. This was followed by the belief that mathematics is relevant to real-life situations ($M = 3.93$, $SD = 1.111$), affirming Ciftci's (2015) findings. Other significant drivers included previous positive experiences ($M = 3.73$) and intrinsic motivation/curiosity ($M = 3.36$), which is identified in the literature as a forceful determinant of learning outcomes.

Teacher Perspectives

Teachers reported that students who excel often form study groups and view challenges as growth opportunities. Conversely, a lack of interest was often tied to the perceived irrelevance of the subject to future career goals, particularly in non-science programs. Teachers also noted that clear explanations and the use of real-world applications are critical factors in reducing learner anxiety.

Discussion and Conclusions

The findings suggest that student interest is malleable and heavily dependent on perceived relevance. The lack of a gender gap indicates that instructional shifts or shifting societal norms may be closing traditional divides (Bakar & Tahir, 2009).

Educating for Change and Epistemic Justice

In alignment with PME-NA 2026, the significant impact of the "program of study" highlights an "epistemic injustice" where students in certain academic tracks feel systemically excluded from the perceived utility of high-level mathematics. To "educate for change," mathematics must move beyond rigid curriculum delivery to become an inclusive experience that empowers all learners, regardless of their career track. Current research emphasizes that providing adaptive formative assessment strategies across varying mathematical competency demands is essential for this transition.

Recommendations

1. *Contextualized pedagogy*: Teachers should adapt methods to emphasize practical applications in diverse fields like economics and art to engage students across all programs (Ainley & Ainley, 2011; Tomé, 2025).
2. *Fostering self-efficacy*: Interventions should focus on building confidence and rewarding perseverance, leveraging socio-constructivist teaching methods.

3. *Mitigating anxiety*: Institutions should strengthen technical and emotional support services to reduce mathematics-related stress.

Implications of the Findings to the Teaching and Learning of Mathematics as Well as Policy Makers

Although the study has limitations, the findings show that students' interest in mathematics is not significantly associated with gender or age, but is significantly related to program of study. In addition, psychological factors such as willingness to exert effort, perceived relevance of mathematics, prior positive experiences, and intrinsic motivation strongly shape students' interest. Teachers also observed that students' engagement is influenced by perceived usefulness of mathematics for future careers and by instructional clarity and real-life applications.

For the teaching and learning of mathematics, this implies the need to strengthen instructional approaches that enhance perceived relevance and engagement across all student groups. Teachers should emphasize real-life applications of mathematics in diverse contexts and support students' willingness to persist in learning through positive reinforcement and clear explanations. Attention should also be given to creating supportive classroom environments that reduce anxiety and build on students' prior positive experiences to enhance interest and engagement.

For policy makers, the significant differences in interest across programs of study suggest the need to ensure that mathematics curricula are meaningfully relevant across all academic tracks, not only science-oriented programs. Curriculum planning should therefore promote the applicability of mathematics in varied fields to sustain interest among all learners. In addition, policy support for teacher professional development is necessary to strengthen the use of real-life examples, clear instructional strategies, and supportive feedback practices that foster student engagement in mathematics.

Acknowledgements

We appreciate the efforts put in by all SHS students before, during and after the study.

Mathematizing is central to math education, yet how young students structure real-world situations remains underexamined. This study addresses this gap by proposing the Units-In-Mathematizing (UIM) lens, focusing on the referents students attend to and coordinate when making sense of situations. We analyzed first-grade students' mathematizing in a coding-math context using the UIM lens. Findings reveal that tensions in coordinating units such as count of moves and directional change influenced students' choice of operations and equations in their mathematizing process. These results suggest that students' interpretive structuring of a situation shape the direction of their mathematizing. We conclude with implications for instruction, emphasizing making students' referential choices explicit in integrated STEM contexts.

Keywords: Cognition, Computational Thinking, Elementary School Education, Modeling

Mathematizing is essential for constructing mathematical meaning (Freudenthal, 1968; Schoenfeld, 2017). While modeling research (Blum, 2011; Kaiser & Sriraman, 2006) defines mathematizing as transforming real models into mathematical ones (Blum & Leiß, 2007), the initial cognitive process of interpreting a situation to form a real model remains underexamined. Additionally, existing studies predominantly focus on older students and text-based problems (Doerr & English, 2003; English, 2006; Kenderov, 2018). Thus, a gap exists in understanding how young students interpret real, non-textual situations through their interactions with them. This study addresses this gap by proposing a *Units-in-Mathematizing* (UIM) lens. Drawing on previous literature, this framework analyzes how young students cognitively organize and coordinate *units* within integrated coding and mathematics contexts. By illustrating this lens through empirical data, we demonstrate its utility in revealing the nuances of students' interpretive processes. The study concludes with implications for mathematics instruction and research on mathematizing.

Literature Review

Units-In-Mathematizing (UIM)

Unitizing has primarily been studied within multiplicative thinking (Clark & Kamii, 1996; Lamon, 1994; Zwanch & Wilkins, 2021) and fraction learning (Hackenberg, 2007; Norton et al., 2015; Steffe & Olive, 2010), emphasizing how students coordinate units of one. Further research on quantitative reasoning (Tasova & Moore, 2025; Thompson, 2011) and model-eliciting activities (Chamberlin & Moon, 2005) highlights the importance of determining which quantities and relationships to prioritize. Extending the scope of units from units of one to referents that play a role in mathematical reasoning, we define *Units-In-Mathematizing (UIM)* as *any aspects or factors of a situation that students take up and use as units of their interpretation of the situation*. The focus of the UIM lens is not every referent that students notice in a situation;

rather, it attends to the referents that students identify, coordinate, and use as anchors for their mathematizing. In this sense, UIM extends prior work on unitizing and quantitative reasoning by broadening the scope of units beyond units of one, quantities with measurable attributes, or relationships among quantities, to include any referent that students take up as a *mathematizing unit* in constructing their interpretation of a situation (hereafter, referred to as *UIM)*. By adopting this lens, we can examine students' mathematizing more broadly, tracing how they organize their reasoning around the referents they take up as meaningful units in a situation.

CT-Math Integration as a Productive Context for Various Units

Computational Thinking (CT) research on decomposition (Bers, 2020; Relkin et al., 2021), breaking complex goals into manageable parts (e.g., Murcia & Tang, 2019), suggests that learners must decide what constitutes a unit of action or subtask. From this perspective, decomposition creates opportunities for multiple aspects of a context to become candidate units. Unlike word-problem contexts where units are often pre-determined by the text (Galbraith & Stillman, 2006), CT-math integrated environments require students to actively designate and coordinate these candidate units for coding while mathematizing them through mathematical representations. In this sense, CT-math tasks foreground not only how students break a goal into parts, but also how they mathematize the whole context by attending to specific aspects as *UIM*. Accordingly, these hybrid settings provide a productive environment for examining how students navigate and coordinate diverse *UIM* within complex, non-textual situations.

Research Question

This study investigates young students' mathematizing in a CT–math integrated setting through the following question: *In what ways does the UIM lens provide insights into the cognitive analysis of young students' mathematizing within an integrated CT–mathematics context?*

Methods

Data Collection

Setting and participants. This study was conducted in a first-grade duallanguage immersion classroom in the western U.S. From a larger project called SPARC-Math (Phase 1 of NSF Grant #2300357; N=68), we purposively selected a focal group of four students (Sarah, Cindy, Ron, and Riley (pseudonyms)). This group was chosen because their interactions during lessons involving forward and backward codes captured diverse and contrasting ways of mathematizing the same coding tasks, providing rich data for a UIM analysis.

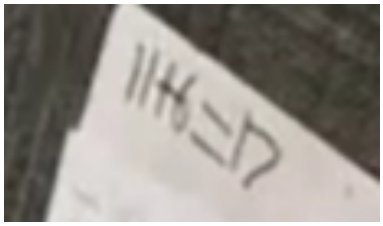
Lesson design. We implemented four 30-minute integrated lessons using Robot Mouse and a custom number line. The first two lessons introduced the coding system (forward/backward moves and rotations). The final two lessons, facilitated by the first author, involved group activities where students solved coding sequences and represented them as mathematical equations.

Data Analysis

We analyzed 60 minutes of video from the final two lessons, focusing on three episodes where students' mathematizing varied significantly. An episode was defined as a coding problem followed by the task of writing a corresponding equation. First, we transcribed verbal explanations and documented gestures and written work. Guided by the UIM lens, we identified moments where students produced mathematical representations and examined their underlying *UIM*s (e.g., number of moves, starting/ending positions). Finally, we traced whether these *UIM*s were maintained, shifted, or conflated, and how these dynamics shaped their equations and justifications.

Results

Mathematizing a Robot's Movement on the Number Line Using a Math Equation

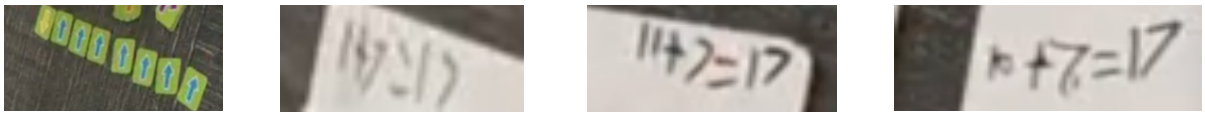


Throughout the two lessons, students were asked to write a mathematical equation representing the robot's movement on the number line. As they mathematized different coding problems using equations, diverse *UIM*s emerged in their reasoning.

Episode 1, Lesson 3: Six Forward Codes and + 6.

In the third lesson, the first task required students to create a code that would move the robot from 11 to 17. All four students used a sequence of six forward arrow cards (Figure 1). When asked to write a mathematical equation representing their code, all students wrote 11 + 6 = 17 (Figure 1). When prompted to explain their reasoning, Riley responded, "*I did it because that's how much the robot went in the math, so I wrote the equation*."

(Code)



(11 + 6 = 17)

Figure 1: Six Forward Codes and Students' Corresponding Mathematics Equations

Using *UIM* lens, we interpret that students attended to the robot's net change in position (from 11 to 17) as *UIM*, which aligns with the six forward moves in their code. They mathematized the situation using addition, coordinating the starting position (11), the movement (6 forward movements), and the ending position (17) in a single equation. Notably, this episode suggests that a forward command does not inherently entail addition; rather, addition becomes appropriate when forward movement is interpreted as an increase in position.

Episode 2, Lesson 3: One Backward Code and Seven Forward Codes

In the second problem where the robot moved from 11 to 17 using 1 backward and 7 forward moves, students' equations varied based on their *UIM*. Cindy wrote an equation (1 + 7 = 17 in Figure 2) linking movement-based quantities (1 backward, 7 forward) directly to the endpoint (17). When explaining her reasoning, Cindy said, "*One means, it went backward one and it went forward seven and it landed on 17*." We interpret this as a misalignment where she attended to the count of code cards as a *UIM* without taking up directionality or net change on the number line as units in her mathematizing process. Cindy's equation makes visible a *UIM* distinction that remained implicit in Case 1, where total movement and net change coincided. In contrast, Sarah and Rob (11 + 7 = 17) took up the starting and ending positions as *UIM* as well as the total count of cards (7), rather than the net displacement. Riley (10 + 7 = 17) coordinated the total moves with the endpoint by introducing an intermediate number (10), representing the robot's position after the initial backward move. Taken together, these equations illustrate that even in the same coding situation, students' mathematizing can differ substantially depending on which aspects of the robot's movement they take up as *UIM* in their interpretations.

(Code) (Cindy : 1 + 7 = 17) (Sarah & Rob: 11 + 7 = 17) (Riley: 10 + 7 = 17)

Figure 2: 1 Backward, 7 Forward Code and the Math Equations

Episode 3, Lesson 4: Three Backward Codes and One Forward Code

For the second task in Lesson 4, the robot started at 5 and landed on 3. After initially using two backward codes, students then created a program using three backward codes and one forward code (Figure 4). When asked to write down a mathematics equation, Ron stopped writing a math equation after writing down 5–3 while Sarah wrote down 5 – 2 = 3, and Cindy and Riley did not write down anything. The facilitator intervened, asking Ron what the 5 and 3 represented. Ron responded, "*it started at 5 and took away 3*." The facilitator then pointed to the one forward card on the floor and asked, "What do we have here?" Ron replied, "one?" and then completed his math equation. Following this, Cindy copied Ron's equation onto her board. The facilitator then engaged Sarah and Riley, asking them to describe the meaning of each number in the equation. The lesson concluded with a discussion on interpreting the movement and numbers in their mathematical representations.

(Code) (Ron) (Sarah) (Ron's complete equation)

Figure 4: Three Backward Codes and One Forward Code with Corresponding Equations

The UIM lens suggests a referential tension in Ron's pause after writing 5−3: the "3" could refer either to the positive count of backward cards or to the directional change (−3) in position. Interpreting the backward moves as "taking away 3," Ron coordinated the starting position (5) and the intermediate position (2) as *UIM* in his equation. Notably, this episode illustrates that the operation used in an equation (addition or subtraction) is not determined by a command label (forward/backward) alone, but by which aspects of the activity students take up as *UIM*. Meanwhile, Sarah (5 – 2 = 3) focused on the start (5), end (3), and net change (2) as *UIM* without incorporating the full arrow-card sequence in her representation.

Discussion and Limitation

The UIM lens reveals that young students' mathematizing in CT-integrated contexts begins with a process of negotiating *units-in-mathematizing* (UIM) rather than simple translation. This suggests that the way students interpret and organize the physical situation, specifically, how they determine what counts as *UIM*, directly shapes the direction and structure of their mathematizing. As seen in the tensions between representing "count of moves" and "directional change," the choice of mathematical operations is not a direct mapping of coding labels, rather it emerges from how students cognitively structure the situation. These findings highlight that CT-

math environments function as productive spaces where students explicitly coordinate diverse *UIM* to construct mathematical interpretations of situations. For instruction, these findings suggest that teachers should support students in articulating their referential choices before moving directly to equations or code. Rather than treating mathematizing as immediate symbolic translation, teachers can ask students what they are taking as *UIM* in the situation, how those units are represented numerically, and why those units call for particular operations or representations. This preliminary study is limited by its small focal group and the specific affordances of the Robot Mouse. Future research should investigate how these *UIM* patterns generalize across diverse student populations and different CT tools to better understand the stability of students' interpretive mathematizing processes.

SHADES OF MISCONCEPTION: HIERARCHIZING IMPROPER FRACTION ERRORS VIA UNITS COORDINATION

The theory of scheme and units coordination has been established as a pivotal analytical framework for investigating students' mathematical knowledge. Employing the theoretical lens, the present study explores the cognitive mechanisms underlying students' errors on an improper fraction task. By analyzing responses from 1,472 students, we hierarchize misconceptions into three distinct tiers based on the nature of activated schemes. Results indicate that their errors reflect varying levels of units coordination: students who engaged in reversible reasoning but failed to use three levels of units as given; those who assimilated the problem solely with a unidirectional scheme; and those not invoking an improper fraction scheme. We argue that these error patterns evidence developmental trajectories, providing a foundation for differentiated instruction and promoting equity by legitimating the rationality of marginalized learners.

Keywords: Assessment, Cognition, Learning Theory, Number Concepts and Operations

Introduction

The study of student errors and misconceptions in mathematics education has a long-standing history, evolving alongside shifts in educational philosophy and psychological trends. Early research, particularly in the early 20th century, was heavily influenced by behaviorism in the United States. During this period, researchers focused on listing types of errors or analyzing their frequency in arithmetic, treating errors primarily as targets for elimination (Radatz, 1979, 1980). However, with the emergence of cognitive psychology in the 1970s, errors came to be understood not as mere mistakes, but as meaningful indicators of how students process information based on systematic rules (Ginsburg, 1977).

A constructivist paradigm, in conjunction with the cognitive approach, had elucidated a more nuanced understanding of students' misconceptions. From a constructivist standpoint, misconceptions were re-evaluated as inevitable and productive resources that emerge when knowledge valid in limited contexts is extended to new domains (Smith et al., 1993). The focus of research has shifted toward illuminating the unique cognitive rationality inherent in students' reasoning. Empirical studies in various domains, such as algebra (Clement, 1982) and probability (Shaughnessy, 1977), have substantiated that these errors are products of students' own systematic thinking. To date, research has endeavored to characterize students' unique cognitive frameworks by scrutinizing their diverse problem-solving strategies and responses and classifying them into specific typologies (e.g., Mathaba et al., 2024; Säfström et al., 2024).

However, we argue that treating student errors as discrete, mutually exclusive categories and merely enumerating them in parallel is insufficient to fully account for the concomitant cognitive mechanisms and the interconnected developmental trajectories of these errors. While the pathways to correct solutions are relatively canonical, the manifestations of misconceptions might exhibit extraordinary heterogeneity; consequently, treating them as mere isolated entities constrains the capacity to holistically explain the cognitive processes engaged in specific conceptual domains. In order to harness misconceptions as genuinely productive pedagogical

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

resources, it is imperative to delineate the 'interrelationships' or 'hierarchies' inherent among them. If it is established that certain erroneous strategies are cognitively more sophisticated or possess greater potential toward the target concept than others, error analysis would remain as a promising methodological approach for addressing fundamental issues in mathematics learning (Radatz, 1980) and serve as an essential guideline for teachers to make pedagogical decisions (Simon, 1995).

This paper reports the initial results of our data analysis, categorizing students' diverse errors through the lens of *scheme* and *units coordination* when solving an improper fraction problem. We aim to identify the varying cognitive abilities inherent in these *marginalized learners* – whose cognitively valid reasoning is routinely undetected and dismissed merely as 'incorrect' in traditional assessments – and provide tangible implications that facilitate differentiated pedagogical interventions tailored to each level of (mis)understanding.

Theoretical Perspectives

Scheme and Units Coordination

von Glasersfeld (1995) defined a scheme as a cognitive structure comprised of three parts: an 'experiential situation,' an 'activity,' and an 'anticipated result.' Steffe (2010) incorporated a 'generated goal' into this framework, emphasizing child's intrinsic motivation as the pivotal mechanism orchestrating the overall functioning of the scheme.[1]

Units coordination refers to the organizations of a sequence of mental operations using units—such as *partitioning* a given referent unit, *disembedding* a part, and *iterating* it multiple times—to achieve a specific goal (Steffe & Olive, 2010). Investigating these units-coordinating activities allows for an assessment of quantitative reasoning that surpasses computational proficiency; specifically, such investigation reveals the extent to which a learner assimilates a problem situation into a structure of *nested* units and utilizes this structure flexibly *prior to activity* (Shin & Lee, 2024; Thompson, 1988). Drawing upon scheme theory, this study defines '4/3 scheme' and 'reversible 4/3 scheme' and employs them as analytical tools to examine students' fraction problem-solving activities.

4/3 Scheme and Reversible 4/3 Scheme[2]

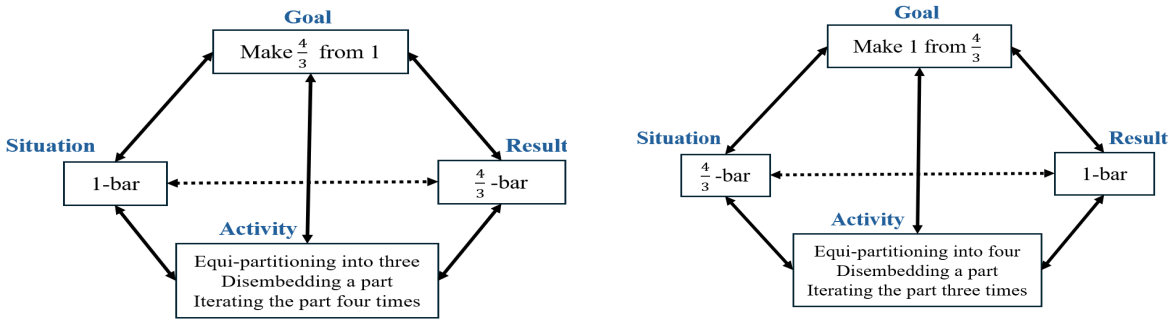

Figure 1. 4/3 Scheme (Left) and Reversible 4/3 Scheme (Right)

[1] For a detailed history of the development of scheme theory, refer to Tillema & Gatza (2024).

[2] Although this study builds upon the foundational concepts of the Iterative Fraction Scheme (Steffe & Olive, 2010), we operationally employ the term 'reversible 4/3 scheme' to denote the specific goal-directed operations elicited by the assessment task, acknowledging the constraints of a large-scale cross-sectional design.

A 4/3 scheme is activated with the goal of constructing an improper fractional quantity, 4/3 from a referent unit of 1. Given a single bar, a student partitions it into three to generate a unit fractional part, 1/3, and iterates the part four times to construct 4/3, with which the activated scheme is closed (Figure 1, Left). While this demonstrates that the student has constructed the improper fraction 4/3, comprising a *three-level units structure* of [1/3, 1(3/3), 4/3] through the units-coordinating activity, it does not necessarily imply that she used the three-level structure *as a given prior to* the activity, nor does it warrant the persistence of the structure once the task is completed.

Meanwhile, whether a student has assimilated 4/3 with the three-level units structure can be corroborated by the execution of a reversible 4/3 scheme. The concept of reversibility entails reconstituting the initial referent unit, 1, from the result, 4/3, of the 4/3 scheme. As shown in Figure 1 (Right), the reversible 4/3 scheme aims to construct the original unit bar of 1 when 4/3 of the bar is given. To accomplish it, the student performs a units-coordinating activity of partitioning the given 4/3-bar into four to construct a unit fraction of 1/3 and iterating it three times to construct the referent unit of 1. The manifestation of such reversibility implies that she conceives the nested composite unit of 4/3 comprising four 1/3s without losing the referent unit of 1 in which the fractional unit of 1/3 is embedded. It serves as definitive evidence that the student has developed to a cognitively higher level, constructing improper fractions as 'numbers in their own right' that are measurable at any time (Hackenberg, 2010).

Methods

Data Collection and Participants

The data used in this paper were drawn from part of the data collected for the ASFK_AI (Assessing Students' Fraction Knowledge with AI) project, which aims to develop an AI-driven constructed-response assessment model for fraction knowledge. Drawing upon prior research, the research team developed six items designed to diagnose students' stages of units coordination and construction of relevant schemes within fractional contexts. The assessment was administered to a total of 1,472 students in South Korea (318 fifth graders, 657 sixth graders, and 497 seventh graders). This paper focuses on analyzing students' solutions to the task devised to assess construction of 'reversible 4/3 scheme' (Figure 2).

The length of Bar A is 4/3 of that of Jinsu's bar. Draw Jinsu's bar using Bar A and explain how you draw it.	**Draw your bar here. Write your explanation in the box below (Bar A)**
	(Explanation)

Figure 2. Task Designed to Assess Reversible 4/3 Scheme[3]

Data Analysis

Among the 1,472 participants, 713 (48.4%) provided correct answers, whereas 759 (51.6%) were deemed incorrect; the latter group consisted of 611 (41.5%) overt errors and 148 (10.1%) indeterminate responses, including no responses. In contrast to previous research that primarily relied on students' drawings for analysis (e.g., Norton & Wilkins, 2009, 2012), written explanations were incorporated as one of the evaluative components. We sought to strengthen

[3] This task has been translated from the original Korean for this publication.

the validity of our inferences regarding students' units-coordinating operations by corroborating the evidence found in their drawings with the reasoning manifested in their written accounts.

Preliminary Results and Discussion

Students who provided overt-incorrect responses (611, 41.5%) were categorized into three primary groups—W1, W2, and W3— with each group further divided into several subgroups (Table 1). This report presents the initial result of analysis, focusing on the distinctive characteristics of each group within the incorrect category. Due to space limitations, this paper primarily outlines the overarching characteristics of each tier. To provide full transparency regarding how specific cognitive inferences and categorizations were made, our conference presentation will explicitly feature representative excerpts and student drawings, illustrating the nuanced decisions behind subgroups such as W2-3.

Table 1: Classification of Students' Incorrect Answers Based on Activated Schemes

Group	Activated Scheme	Subgroup(N=1472)	Drawing
W1	Reversible 4/3 Scheme	W1-1 (30, 2%)	Divide Bar A into 4 and mark 1 part.
		W1-2 (34, 2.3%)	Divide Bar A into 3 and mark 2 parts.
W2	4/3 Scheme	W2-1 (315, 21.4%)	Draw 4/3 of Bar A.
		W2-2 (17, 1.2%)	Draw 4/3 of 1/2 (or 1/3) of Bar A.
		W2-3 (9, 0.6%)	Draw 4/3 of Bar A and mark 1 part OR Divide Bar A into 3 and mark 1 part.
		W2-4 (29, 2%)	Draw 4/3 of Bar A and mark 3 parts.
W3	No Scheme Identified	W3-1 (27, 1.8%)	Divide Bar A into 3 (Others).
		W3-2 (38, 2.6%)	Divide Bar A into 4 (Others).
		W3-3 (69, 4.7%)	Draw a bar longer or shorter than Bar A with no partitioning.
		W3-4 (13, 0.9%)	Divide Bar A into a number other than 3 or 4.
		W3-5 (30, 2%)	Draw multiple copies of Bar A.

We established a hierarchical relationship among the three groups (W1 > W2 > W3) according to the schemes implemented. The highest tier, W1 students activated 'reversible 4/3 scheme'; they demonstrated reversibility by recognizing the given bar as 4/3 and aiming to reconstruct the initial unit of 1. However, they conducted units-coordinating operations without assimilating 4/3 with a three-level units structure composed of four 1/3s —for instance, partitioning the bar into four and marking one part. The subsequent group, W2, activated '4/3 scheme' without reversibility; despite the problem stating bar A represented 4/3, these students treated it as a reference unit of 1 and attempted to construct 4/3 of it. The lowest tier, W3, showed no activation of either scheme, lacking evidence of goal-directed operations related to improper fraction construction (e.g., drawing three additional bars of the same size as bar A). This classification reveals that responses, though all incorrect, stem from varying levels of units-coordinating ability. Such findings provide a concrete framework for utilizing misconceptions as 'productive resources' to facilitate differentiated instruction (Hackenberg et al., 2021).

It is also noteworthy that, except for subgroup W2-1, each of the remaining subgroups accounts for less than 5%. The low prevalence of these diverse atypical responses suggests a potential risk of them being overlooked or dismissed as 'unidentifiable' errors in mathematics classrooms. However, the result of our study demonstrates that even these minority students are striving to understand and solve problems grounded in their own cognitive rationality; they are

actively navigating distinct pathways toward the construction of fraction concepts envisioned by researchers and teachers. Elucidating and legitimating the mathematical thinking of these marginalized students is not only an act of profound respect for their mathematics but also an essential process for promoting *equity* in mathematics classrooms (Hackenberg et al., 2024).

This sequential explanatory mixed-methods study examines how Team-Based Learning (TBL) supports belonging in seventh-grade honors mathematics (n = 13 students). Using social network analysis (SNA), we identified patterns of belonging over a six-week unit. SNA revealed four distinct patterns of network integration associated with belonging: peripheral to central, remains central, remains peripheral, and central to peripheral. Findings suggest fostering belonging requires attention to individual positioning within collaborative structures and ongoing negotiation of participatory norms. This study contributes a novel SNA approach to examining belonging and highlights implications for designing collaborative mathematics instruction.

Keywords: Affect, Emotion, Beliefs, and Attitudes

Introduction

A sense of belonging plays an important role in shaping students' motivation, engagement, and achievement in mathematics classrooms (Barbieri & Miller-Cotto, 2021; Good et al., 2012; Ryan & Deci, 2002). In mathematics education, belonging is more than feeling accepted by others (Good et al., 2012), it means being recognized as a real contributor to the shared process of doing mathematics (Barbieri & Miller-Cotto, 2021; Darragh, 2013; Hamm & Faircloth, 2005). Research shows that belonging can be supported when teachers design tasks that promote interdependence, highlight diverse ideas, and build mutual respect among students (Anderman, 2003). Collaborative learning (CL) is one effective way to foster a sense of belonging by encouraging teamwork, problem solving, and mutual support. CL helps students connect with classmates and recognize the value of their ideas (Cohen & Lotan, 2014). In this study, we utilize, Team-Based Learning (TBL), a structured CL model (Michaelsen & Sweet, 2011) that creates opportunities for students to develop belonging through four elements: 1) strategically formed, permanent teams, 2) readiness assurance process, 3) application activity, and 4) peer feedback. TBL offers teachers meaningful ways to monitor and support students' sense of belonging such as iterative rounds of instructor-screened peer feedback. Drawing on Watson's (2023) conceptualization of belonging, we operationalized one aspect of belonging—students' integration into the mathematics class collaboration network—through social network analysis. We do not claim that network position fully captures belonging; rather, collaboration network integration provides one observable indicator of students' opportunities to experience belonging within the mathematics classroom. To contribute to the research on how CL may support students' belonging in mathematics over time, we sought to answer the research question: *How is*

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

students' sense of belonging reflected in their participation within the collaboration network of a middle school mathematics class, and how does this participation change over time?

Theoretical Perspectives

Through a sociocultural perspective, students' sense of belonging includes their affective responses (Cobb & Hodge, 2002) such as feeling "accepted, respected, included and supported by others" (Goodenow, 1993, p.80) as well as their participation in the mathematical community. Watson (2023) identifies five factors of belonging in mathematics: 1) *You see me*, 2) *I see myself*, 3) *Others see me*, 4) *I am valued*, and 5) *I can grow*. In other words, students experience belonging when their ideas are acknowledged (*You see me*), when their thinking shapes class discussions (*Others see me* and *I am valued*), and when they see themselves as members (*I see myself*) of a mathematical community (Morales-Chicas & Graham, 2021). Classrooms that promote students' sense of belonging balance academic challenge with relational support (*I can grow*) by encouraging them to take risks (SanGiovanni et al., 2020), explain their reasoning (Thanheiser et al., 2025), and engage in collaborative problem solving (Slavin, 1991). Thus, belonging is relational and participatory. Our study provides a novel approach of leveraging social networking analysis (SNA) to visualize and quantify the connectedness of the mathematics class collaboration network as well as to describe students' belonging over time using student-level descriptive statistics. This approach demonstrates the factor of belonging, *Others see me,* through recognition of mathematical collaboration.

Methods

This mixed-methods study follows a sequential explanatory design (Creswell & Plano Clark, 2018) to identify and describe emerging patterns of belonging within the seventh-grade honors mathematics class collaboration network.

Data Collection

The research team for this study includes $n = 4$ mathematics education researchers with K-12 mathematics teaching experience as well as $n = 2$ in-service mathematics teachers one of which we implemented the six-week unit in their seventh-grade honors mathematics class. We implemented TBL in a 14 person seventh-grade honors mathematics class at a rural, Title I school with a mathematics teacher with $n = 3$ years of teaching experience. In the class, 92.86% of the students (female $n = 9$, male $n = 4$) participated in the study, with one student not assenting. During the six-week unit, TBL was implemented once per week as a follow-up to direct instruction the day before.

SNA data regarding students' collaborative relationships in the seventh-grade honors mathematics class were collected weekly after the application activity during the TBL unit. Qualitative data to explain the SNA results were collected through weekly peer feedback (Sanders et al., 2024) and post TBL open-ended reflections.

Data Analysis

For the SNA data transformation, collaborative connections (i.e., ties) between students in the seventh-grade honors mathematics class were modeled using undirected ties by creating a symmetrized collaboration matrix for each time point (i.e., week 1 = time point 1) where all ties were reciprocal (Borgatti et al., 2022). This approach uses the "OR" or "union" rule (Krackhardt, 1987) as well as accounts for missing data (Borgatti et al., 2022; Žnidaršič et al., 2012) through the assumption of mutual ties (i.e., if one student selects another there is connection between them). For each time point we calculated network-level descriptives (i.e., density, connectedness, percent homophilous ties) and a node-level measure of belonging, normalized eigenvector

centrality. We selected this measure of centrality since it describes the degree to which a student collaborates with peers who are themselves well-connected, reflecting our definition of belonging as students' ongoing integration into the mathematics class collaboration network grounded in Watson's (2023) factors of belonging, *Others see me* and *I am valued*. While network centrality cannot directly measure students' internal feelings of belonging, it provides a useful indicator of how students are positioned within the classroom collaboration structure and the extent to which their participation is recognized by others.

Next, SNA results were used to identify dynamic patterns of belonging: 1) peripheral to central, 2) remains central, 3) remains peripheral, and 4) central to peripheral. The emergent patterns in the collaboration network were identified using students' normalized eigenvector centralities and network visualization (Borgatti et al., 2022). To establish a threshold distinguishing central from peripheral positions, we used the second quartile (Q2 = 0.08) of all normalized eigenvector centrality scores across students and time points (n = 78 total observations, M = 0.08, SD = 0.07, Min = 0.00, Max = 0.27). The quartile-based cut point reflects the properties of the sample rather than an a priori cut point. Patterns of belonging in the collaboration network were distinguished using a students' initial (Week 1) and final (Week 6) normalized eigenvector centrality as well as visual inspection of the network plots.

Following the identification of patterns of belonging, the SNA results and qualitative data were blended to describe the four emergent patterns of belonging (Creamer, 2018). In this phase, the SNA results were integrated and interpreted through the discussion of interwoven qualitative data. Qualitative data from students' peer feedback and post-survey open-ended responses are triangulated (Creswell & Plano Clark, 2018) to provide inter- and intra-belonging pattern comparisons using Watson's (2023) factors of belonging. Of note, we focus on the factors *Others see me, I see myself, I am valued*, and *I can grow* since we utilized peer feedback and student self-reflection as the qualitative data sources.

Findings

Across the six-week unit, the mathematics classroom collaboration network became increasingly cohesive (see Table 1). This shift in the network was not linear but fluctuated between fragmentation and cohesion. Within these fluctuations, students experienced differing opportunities for integration into the network. Our discussion of patterns of network integration associated with belonging highlights the experiences of Alicia (peripheral to central), Crystel (remains central), Derek (remains peripheral), and Jessica (central to peripheral).

Table 1: Collaboration Network Descriptive Statistics

	Week 1	Week 2	Week 3	Week 4	Week 5	Week 6
Network Density	0.12	0.14	0.18	0.18	0.12	0.19
Connectedness	0.37	0.71	0.85	0.85	0.31	0.85
Percent Homophilous	100.00	81.82	78.57	57.14	100.00	93.33

For some students, belonging developed through increasing integration into the collaboration network across the six-week unit. These students moved from more peripheral positions toward greater participation and recognition within the mathematics collaboration network. Alicia's experience in the collaboration network illustrates how belonging developed over time. Alicia moved from the margins of the network (Week 1 centrality = 0.03) toward the core (Week 6 =

0.13). Early feedback recognized her kindness while Greg requested she "speak a little more." By Week 3, Crystel described her as "really smart" and noted she "helps the team figure out the answer," signaling growing peer uptake of her contributions. By week 6, Eli called her "a good leader" and Greg appreciated that she "helped me when I was stuck." The progression from "speak a little more" in week 1 to "good leader" in week 6 reflects increasing participation and recognition within the network over time and represents *I can grow*.

While some students experienced increasing integration into the collaboration network, other students maintained relatively stable access to belonging throughout the unit. Crystel held a central position throughout (Week 1 = 0.15, Week 6 = 0.14), beginning as a broker connecting the two network components. Her peers consistently recognized both competence and a collaborative orientation: Brittany described her as "always wanting to listen to others." The stability of her position and the recurring affirmation in her feedback reflect sustained access to *Others see* me and *I am valued*. However, even among students with sustained belonging, participation was not entirely stable.

For several students, belonging became fragile, unstable, or remained persistently out of reach despite participating in the same collaborative learning environment. Jessica represents the clearest example of movement from central to peripheral participation. She began with the second-highest normalized eigenvector centrality in the class (Week 1 = 0.20) and ended at complete isolation (Week 6 = 0.00). Her peer feedback highlighted her efforts in helping the team despite missing several days of class leading up to the team activities. Examining what her team members requested of her though surfaces that within her efforts students recognized the need for her to "be more serious" and to "recheck her work, because she was somewhat rushing." Her feedback in week 2 (i.e., "slow down"), echoes the week 1 requests demonstrating that Jessica is detached from the factor of belonging; *I can grow*. In the remains peripheral pattern, Derek stayed below the Q2 threshold in both Week 1 (0.00) and Week 6 (0.03), despite a temporary mid-unit peak. Peers acknowledged his ability (e.g., "he is smart") but repeatedly requested he "stay on task" and "not goof off" across the unit, indicating that his mathematical presence was recognized while his collaborative participation was not taken up as consequential.

Discussion and Conclusions

The four patterns demonstrate that engaging in CL through TBL did not guarantee students developing or maintaining belonging in the network. Students moved in and out of central participation, illustrating Faircloth and Hamm's (2011) description of dynamic adolescent peer networks. Further, integration into the collaboration network was determined less by perceived mathematical competence than on how students' peers took up students' contributions as legitimate (Kotsopoulos, 2014; Lave & Wenger, 1991). These findings highlight the need to investigate individual students' positioning within the collaboration network and how to support the needs of all learners for developing belonging.

AFFORDANCES AND LIMITATIONS OF DUAL ENROLLMENT MATHEMATICS STUDENTS' EXPERIENCES

Tami Dashley Shah
University of Massachusetts Dartmouth
tdashleyshah@umassd.edu

Beste Güçler
University of Massachusetts Dartmouth
bgucler@umassd.edu

Dual enrollment (DE) programs, in which students take college courses while in high school, have been utilized in the US to enhance students' access to and success in college. Existing research has mainly focused on the effects of DE programs through quantitative, outcome-oriented frameworks; few studies utilize qualitative, sociocultural approaches to examine DE students' experiences based on their own voices. Through a case study, we address this need by exploring how three high school DE students taking a college mathematics course on a college campus describe their DE experiences. We use theme analysis to identify the emerging affordances and limitations of DE students' experiences based on their responses to semi-structured interviews. We then discuss the implications of our findings for research and practice.

Keywords: Dual Enrollment, Student Perspectives, High School Education, Undergraduate Education

Dual enrollment (DE) programs, in which high school students take college courses, have been utilized in the US to enhance students' access to higher education, college readiness, and interest in pursuing STEM degrees (An & Taylor, 2019; Cevallos et al., 2016; Hoffman, 2003; Jamieson et al., 2022). Existing research mainly uses outcome-based approaches and quantitative measures (e.g., academic performance through course and college grades; college enrollment, retention, and graduation rates) to examine the effectiveness of DE programs (e.g., Allen & Dadgar, 2012; An & Taylor, 2019; Blankenberger et al., 2017; Henneberger et al., 2022). While some studies explored DE students' self-perceptions as college students and adaptation to college (e.g., Cevallos et al., 2016; Kanny, 2015; Karp 2007; Lile et al., 2018), few studies examine DE students' experiences through qualitative and sociocultural approaches that prioritize students' own perspectives and voices (McGowan Bucci & Simpson, 2022; Williams, 2015). Our work focuses on this area needing more attention by addressing the following research question: How do three high school students taking their DE courses on a college campus describe their DE experiences? Exploring DE students' experiences through their own voices, particularly when taking courses in a college setting, can help examine the extent to which their experiences align with the goals of DE programs in easing the transition from high school to college and provide insights on how to improve DE programs and models.

Theoretical Framework

Using a sociocultural perspective, we view DE students as operating in and transitioning between different communities of practice (Lave & Wenger, 1991). Although high school and college communities have similarities (e.g., academic and educational focus), they also differ in terms of epistemological, institutional, and cultural presuppositions, expectations, norms, and practices to which participants need to adjust (Clark & Lovric, 2008; Di Martino et al., 2023; Gueudet, 2008). Consistent with our sociocultural framing, we purposefully focus on students' *descriptions* of their experiences in their narratives rather than framing our work via beliefs. *Belief* is a construct through which researchers have examined students' views about their experiences by framing beliefs as internal and stable cognitive entities that can be used as

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

predictors of behavior (Cobb, 2007; Lerman, 2002; Sfard, 2008). Treating beliefs as detached from social and cultural contexts fails to capture the social, discursive, and situated nature of students' practices and experiences (Cobb, 2007; Lerman, 2002). We argue that students' views and positions about their experiences occur within social and cultural contexts and are participatory rather than merely cognitive (Lave & Wenger, 1991; Lerman, 2002; Sfard et al., 2001). By privileging student *descriptions* over *beliefs*, we treat talk as a unit of analysis in itself (Edwards, 1993) and view what students say as the situated accounts of their evolving narratives through which they construct meaning instead of viewing student descriptions as windows to their inner states such as beliefs or perceptions.

Methodology

We used a case study approach to examine DE students' descriptions of their experiences (Merriam, 1998). DE programs have been implemented in the US through a variety of models including students taking DE coursework only at their high schools (either with a college or qualified high school instructor); both at their high schools and a college campus; and only at a college campus, where they take courses with regular college students or in special sections composed solely of DE students (An & Taylor, 2019; Andrews, 2001). Our case study focuses on the experiences of a group of DE students taking college courses on a college campus together with college students because this model has the most potential in providing students with authentic college experiences (Edwards et al., 2011; Karp, 2007), and a key motivation for students to take DE courses is to gain experiences with college (Kanny, 2015; Lile et al., 2017; McGowan Bucci & Simpson, 2022).

The participants were three high school students, who, at the time of the study, were taking a calculus course at a 4-year university called Tech College (pseudonym) located in northeastern US. Our participants were Catherine, Billy, and Richard (pseudonyms), who all self-identified as Black/African American and attended Eastern High School (pseudonym), where 68% of the students were designated as low-income and consisted primarily of students of color. Eastern High School utilized DE to provide career-oriented coursework for their students in computer science, engineering, and health sciences. All DE students were in the engineering pathway and calculus was the first mathematics course they were taking on the college campus, whereas they took some college engineering courses at Tech College prior to the study.

The data we report here is based on two semi-structured interviews conducted with the students individually. Each interview was recorded and conducted via video-conferencing technologies to allow the greatest flexibility for the students to participate in the study. The first interview elicited general information about the students and their DE program, courses, and overall experiences. The second interview elaborated on each participant's responses in the first interview to provide more in-depth information about their experiences and allowed us to ask additional questions to each participant based on other participant interviews. For example, one of the questions in the first interview was "Can you describe your experiences in your dual enrollment courses?" In the second interview, depending on each participant's responses, we asked questions such as:

> In our last interview, you mentioned that you could not attend your professor's office hours due to your high school schedule. How do you navigate not having access to this additional assistance? What do you usually do when you need help?

Since the second interview was informed by the first interview, data analysis occurred simultaneously with data collection (Merriam & Tisdell, 2015). We transcribed each interview

and used theme analysis (Guest et al., 2012) involving deductive coding derived from our interview questions as well as inductive coding derived from the emerging themes in students' descriptions and narratives. We classified the emerging themes and subthemes as affordances and limitations of DE students' experiences depending on whether they supported or hindered ease of transition from high school to college.

Findings

Affordances of DE Students' Experiences

Deeper conceptual understanding of mathematics. The students reported that taking DE courses assisted them in developing deeper conceptional understanding of mathematics. Through her experiences in her DE calculus course, Catherine made a distinction between two types of mathematical skills: procedural "when you see just like an integration sign and a function it's automatic about what you have to do," and conceptual, where:

> They don't just give you these numbers, they give you … a situation and you have different variables to it … [in] optimization and related rates … you have to paint a literal picture and consider this and this…and you actually have to think about what you have to do.

Although Catherine mentioned that she struggled with optimization and related rates, she also said she appreciated being exposed to them since it supported her overall understanding of calculus. Billy expressed that, while taking his college mathematics courses, he started to understand how "a certain concept is the way it is, and not just how to do it … and how to get from A to B and why I'm getting from A to B in this certain way." Billy further elaborated that his DE mathematics courses allowed him to go "beyond the world of [routine] problem solving and really seeing … why you do things specifically this way and why and how, if you do it another way, then you know it's not gonna work." Richard mentioned how he performed calculations more easily in his DE engineering courses because of the connections he made between engineering and mathematics concepts: "[In] engineering graphics class, they will give you measurements … [but other] measurements you have to calculate it … and I could just look at it and already tell what the measurement was based on the geometry, everything was connected at times." Richard further explained that these moments "uplifted my knowledge or what I thought … of math," indicating enhanced understanding through making connections. The student responses suggested that their DE experiences helped them learn how to solve non-procedural mathematical problems (Catherine, Billy), why a mathematical concept is the way it is (Billy), and make connections between mathematical and other concepts (Richard), which are components of conceptual mathematical understanding (Kilpatrick et al., 2001).

Learning about applications of mathematical concepts. The participants mentioned learning about applications of mathematical concepts in real life and to other disciplines as an aspect of their DE experiences. Catherine explained how the inclusion of real-life applications in her college calculus course helped her see the usefulness of mathematics.

> Catherine: The examples and the problems that we're made to solve in calculus … they were … dealing with planes and bridges and we were calculating different things that people, especially engineers, use a lot. It was good to see math in a practical way and see that it actually is used pretty often.

Billy commented that taking the college calculus course allowed him to "better understand" the "fundamentals" of mathematics, which included "not knowing just how to solve an equation but knowing how to apply it to the real world." Billy also noted that "calculus ties into basically

everything related to engineering," suggesting that his DE experiences fostered understanding of applications of mathematics in engineering and the real world. Richard noted "I see math as already in my future solidified, since I want to do engineering," indicating that he viewed mathematics as applicable to engineering. Richard also mentioned that "math is everywhere. I think a lot of people say that but it's just the truth. You need math for everything … math is pretty big in society," suggesting a connection he made between mathematics and real life. The students' DE experiences appeared to have assisted them in making connections that give mathematics meaning through the relationships between mathematical ideas and external contexts (Kilpatrick et al., 2001) and participating in meaningful mathematical practices to help them view mathematics as a tool for interpreting the world (Cobb, 1994).

Development of agentic practices. All students stated that their DE experiences facilitated the development of various practices in support of their agency.

> Catherine: I think that having that type of [college] coursework go along with your normal workload, a balancing those two, I think adds a skill, a time managing skill to the students that take it … Now I am better able to handle a lot of coursework and balance it better with my outside of school life than I was able to before.

Catherine also explained that, to balance her DE and high school coursework, she prioritized her studies each weeknight and utilized her weekends to spend time with family and friends or "catch up on any missed sleep" during the weekdays. Billy similarly stated that he had to alter his study habits when taking DE courses.

> Billy: There's more expected of you because you're a college student and you're approaching higher level education. So, there's no time to really constantly keep having those bad habits and procrastinating a little bit too much … even now, I still have to make sure I don't slack off or anything.

Billy also noted starting to work at a part-time job the previous semester and stated he would have to "finish all my [school)]work before … I go to work. Because I'm not able to do anything at work. So, it's better to get all the stuff I have to do out of the way." Richard, who also worked part-time on the weekends, said "I would always … prioritize early college work over everything" to balance his multiple roles and responsibilities. Based on the student responses, their DE experiences helped them develop practices in support of their agency, where agency refers to managing their participation in different communities of practice and across multiple contexts (Wenger, 1998). From a sociocultural perspective, practices like time management, balancing high school, college, and personal lives, prioritizing responsibilities, and developing productive practices (e.g., avoiding procrastination) are expressions of student agency as students organize and manage their participation and navigate the demands of socially structured systems (Emirbayer & Mische, 1998; Holland et al., 1998).

Enhanced sense of community within DE students. Since all students were in the engineering pathway of their DE program, they took many of their high school and college courses together with the same group of students. As Billy shared, for the last two years, "we've always took the same classes, it's very rare that we were separated … I've pretty much connected with them throughout the years." This sentiment of connection and the formation of a supportive community within the group of DE students was also echoed by Richard, who said "the little bubble we had, it was … like a safe spot for all of us if we needed any help, or we were kind of anxious about the work, just lend a hand and whatnot, just like a community." Similarly, Catherine mentioned feeling a sense of comfort and camaraderie working with her fellow DE

peers as “we know what each other's been through, we know the traumas and other times.” Catherine also detailed how being a part of the DE student community helped her feel more willing to take intellectual risks, such as asking for help, in her DE courses.

> Catherine: When … you're the only one that doesn't know something, it can feel really uncomfortable to ask the teacher for help or ask a random person for help. But if we're all in there together and we're struggling, it's less sad, it's more like funny, we laugh about it, and one of us will maybe get the courage to ask for help.

Catherine mentioned that the students typically had “a free hour” together and would “take that time to do homework and also projects” because each person was “good at different things.” Billy corroborated that the DE students would “always do our homework together” and “would always collaborate.” Richard also shared that when given group projects in their DE courses, the DE students “didn't have to work with college students, we could actually work with each other.”

The student responses indicated that their DE experiences fostered their sense of connection, comfort, and camaraderie with one another; created a safe space for them to take risks and develop trust; and has allowed them to work collaboratively and navigate challenges as they worked towards a common goal, which are components of developing a sense of community (Lave & Wenger, 1991; Wenger, 1998). However, student descriptions of enhanced sense of community formed within their DE peer group contrasted with their feelings of discomfort and alienation when working with college students, which will be discussed later.

Limitations of DE Students’ Experiences

Difficulties with meeting multiple demands. All DE students mentioned struggling with taking high school and college courses concurrently and highlighted challenges in balancing the expectations of all their courses with the limited time they had. Richard pointed out how the students’ schooldays typically ended in evening hours due to their class schedules: “You have to take the bus to go to Tech College … [it is] a time commitment because … we literally got at Tech College at like two [p.m.] and then [class] would end at five [p.m.].” Richard further commented on the limited time he had outside of his coursework, stating “it was kind of crazy, honestly … We don’t have that much time as high school students, because we have a whole day’s worth of work we have to do.” Billy commented on the time DE students needed outside of class to study saying, “be prepared to set a lot of time aside after school and when you get home to do your college work and do your high school work.” Based on her own experience, Catherine discussed what a DE student’s schedule could look like after coming home.

> Catherine: I would get home at six [p.m.], I had three AP [advanced high school classes], and two regular [high school] classes, and the [college] class, and to get all the homework done from six [p.m.] to the time I have to sleep and eat and take a shower and do everything else in the middle of it … I was getting like five hours of sleep.

Billy expressed that, in addition to their full schedules, DE students needed additional time to understand new material they were not yet familiar with in their college courses.

> Billy: I was putting in so much work and putting a lot of time outside of class … to understand what’s actually going on … It was something that was new to me so I didn’t know how to exactly go about approaching the [college] class and the material.

Despite the agentic and productive practices students developed to better manage their time and meet multiple demands they face, the interview responses indicated that the students had ongoing struggles balancing the requirements of high school and college, which, when combined with the demands of their jobs and everyday lives, can lead to stress, exhaustion, and potential burnout in the absence of consistent support structures (Nagy & Hokstok, 2026).

Challenges having an authentic college experience. The participants took classes on the Tech College campus, but they reported not being able to participate in various aspects of college life, which indicated that they could not have authentic college experiences. By authentic college experience, we refer to experiences that make it possible for DE students to fully have access to and participate in (Lave & Wenger, 1991) college activities, practices, and resources. Three subthemes emerged under this theme based on student responses: limited access to general college activities and resources, lack of access to tutoring center and college instructor office hours, and limited sense of community with college students.

Limited access to general college activities and resources. Catherine and Richard commented that their DE schedules allowed for limited time on the Tech College campus and, due to their busy schedules, they could not attend campus events and activities.

> Catherine: Because we have traditional [high school] classes too, it was hard to get that college experience. We were taking the [college] classes, but we couldn't do any of the fun parts of college … So I think we definitely missed out on a lot of the what the other college students actually had to take advantage of.
>
> Richard: There would be events at Tech College that we couldn't go to because we would be in class or it would end before we even got to Tech College … [and] we didn't get to do anything with like the Tech College clubs.

Billy also mentioned the barriers the DE student schedules posed and how this issue prevented him from attending college events by commenting "obviously we're not getting the full college experience." Richard commented on the challenges he experienced utilizing various resources at Tech College. He said that he could not use the gym in the Tech College because DE students did not meet the college's "health insurance requirements." The participants' lack of access to getting "the full college experience" (Billy) including the "fun parts of college" (Catherine) such as participating in college clubs and utilizing college resources (Richard) does not only limit having authentic college experiences but can also hinder DE students' opportunities to socialize and interact with their college peers as well as participate in college communities (Lave & Wenger, 1991; Wenger, 1998).

Lack of access to tutoring center and college instructor office hours. All participants mentioned not being able to attend their college instructors' office hours due to their high school schedules. Billy stated that "office hours, we can't even attend those because it's during high school." Catherine said she could not attend office hours "because they're always at 11 a.m. on a Thursday and I'm in [high] school then." Richard said limited time on campus meant he "never attended tutoring" at the college tutoring center and his college instructor's office hours. He mentioned developing strategies to overcome these issues by working on his assignments early and asking questions in the class.

> Richard: I would just wait until I had class again and then asked my teacher about it in class to get the additional help. Because I would always prioritize early college work over everything … So I'd always start on [assignments] early, so I had time to ask [the instructor] in class about the work.

Similarly, Billy commented that he would "use resources outside of class to understand [the course material] and maybe watch some math videos" to get extra help with his college calculus course. Catherine highlighted how the DE students "definitely use each other a lot for support" in completing their college assignments. While the DE students developed some strategies to get help with their college coursework, lack of access to the college tutoring center and college instructors' office hours limited their opportunities to have direct interactions with university educators, which are opportunities available to typical college students. Lack of access to academic support is a barrier that can impact DE students' academic success in college courses (Barnett & Stamm, 2010; Karp & Hughes, 2008).

Limited sense of community with college students. The participants reported discomfort and alienation while interacting with the college students in their DE classes.

> Billy: They're [college students] just doing their own thing. They have their own school and life and there's not really a chance or too much time to really connect on a deep level … it's not as encouraged as it is in high school … I guess it's uncomfortable in a way.

Richard referred to some interactions with his college-aged peers as "scary", which he attributed to being an "introvert" and "shy." Catherine reported feeling alienated from her college peers, especially in her college engineering courses.

> Catherine: They [college engineering students] would hear you struggling, but would never offer any help, even if they know they can do something … it just felt very separated. It was my high school group all together, struggling together, and then there was them finishing their work in 10 minutes and then leaving the class … [In] my first year engineering classes … the teacher would give the instruction to pair up and they [college students] would just sit there and … not say a word to you … they don't make you feel comfortable … I knew they knew more than me, but they were using that as kind of leverage above me … not putting themselves in a supportive mindset, not making themselves feel like someone that I can ask for help because I feel they would judge me a little, call me stupid.

Catherine also observed a difference in how college engineering students interacted with her compared to male DE students: "they were much more willing to work with him [a DE male student] rather than me, you could see the energy change when they were working with them [male DE students] versus me." Although Catherine added, "it didn't really bother me, but like, it's crazy," her comments suggested experiencing gender-based differences in college engineering courses, which might be why she thought, "you just have to get away from the engineering people"—an alarming view from a Black, female student on the engineering track of her DE program. On the other hand, Catherine spoke fondly of her interactions with the college students in her calculus course and referred to them as "cool people."

The DE students' descriptions of sense of community with each other contrasted with how they described their interactions with college students. The DE students shared feeling discomfort (Billy and Catherine), not connected (Billy), separated (Catherine), judged (Catherine), and scared (Richard) when interacting with the college students in some DE courses. They viewed some of their interactions with college students as indicating potential unwillingness or lack of effort to make deeper connections (Billy); indifference or refusal to offer help and interact (Catherine); and gender-based differences in favor of male DE students (Catherine). The DE students' discomfort interacting and collaborating with college students can

limit their academic learning opportunities and sense of belonging in college communities (Giani et al., 2023; Lave & Wenger, 1991).

Discussion

Our results indicate that the DE students' experiences afforded them some opportunities as well as presented challenges. Taking DE courses on the college campus gave students access to deeper conceptual understanding of mathematics and learning about applications of mathematical concepts. It also fostered students' agentic practices and sense of community with other DE students. The students faced challenges in aspects of college life and reported difficulties in meeting the demands of their high school and college work. Although they found ways to manage their time and prioritize college coursework, they all seemed stressed in the process of balancing high school, college, and everyday life, which can lead to exhaustion and burnout (Nagy & Hokstok, 2026). Students' lack of access to the tutoring center, office hours, and other college activities were tied to their time-related challenges, impacting the authenticity of their college experiences as well as academic and socialization opportunities (Barnett & Stamm, 2010; Karp & Hughes, 2008). The DE students struggled forming communities with college students and experienced discomfort, alienation, and at times, marginalization when interacting with college students, which can lead to fragmentation of their experiences and impair their sense of belonging (Johnson, 2022; Karp, 2007). While some discomfort is expected since the DE students are newcomers entering a college community with different norms and expectations than high school (Clark & Lovric, 2008; Di Martino et al., 2023; Gueudet, 2008), lack of access to college activities and resources except scheduled college coursework can limit DE students' opportunities to form social connections with college students and influence whether they can fully participate or remain peripheral in college communities (Lave & Wenger, 1991; Wenger, 1998).

Research indicates that DE students benefit most from having experiences that closely mirror the college environment such as taking courses on the college campus (Burns & Lewis, 2000; Edwards et al., 2011; Karp, 2007), which is aligned with the main motivation for high school students to take DE courses: gaining college experience (Kanny, 2015; Lile et al., 2017; McGowan Bucci & Simpson, 2022). The student responses in our work suggest that, despite having access to DE courses on a college campus, DE students can continue facing challenges in terms of access, legitimacy, and participation in many aspects of college life (Lave & Wenger, 1991). These barriers can be particularly problematic in relation to the goals of existing DE programs in aiding high school to college transition for students who, like our participants, come from historically marginalized communities and can limit opportunities for engagement, identity development, and belonging, which in turn can influence students' academic learning and participation (Giani et al., 2023; Lave & Wenger, 1991; Wenger, 1998). High schools and post-secondary partners need to coordinate efforts and provide support structures to ensure that DE students have more opportunities to have access to and participate in college communities while also taking into account the time limitations and demands of DE student coursework and schedules (Barnett & Stamm, 2010; Hofmann & Voloch, 2012). Support structures that promote academic as well as non-academic opportunities in college can play key roles in the social integration of DE students into college communities and in cultivating DE students' sense of belonging through opportunities to interact with, expand social networks, and develop supportive relationships within college communities (Garrett, 2022). More research utilizing sociocultural perspectives that also prioritize DE students' own voices can be useful in gaining more insights

on the specific needs of DE students and providing insights on how to improve DE programs and models based on the needs of the students.

EXAMINING JULIA'S FRACTIONAL THINKING IN SMALL GROUP PROBLEM SOLVING DISCUSSIONS ON EQUAL SHARING TASKS

Juanita M. Silva
Texas State University
jsilva@txstate.edu

Imaneh Soleimani
Texas State University
soleimani.emma@txstate.edu

This study examines how a bilingual child, Julia, develops her fractional mathematical thinking through problem-solving instruction over five weeks. Using a qualitative case study, we used the constant comparison method of analysis to trace Julia's evolving fractional reasoning strategies, drawing on her gestures, drawings, and verbal descriptions. Initially, she relied on rudimentary partitioning and non-anticipatory strategies, but gradually Julia demonstrated emergent anticipatory strategies. Initially, she relied on simple partitioning strategies (e.g., dividing in halves) but gradually transitioned to more complex partitioning strategies like partitioning by the number of sharers. These findings offer insights into how responsive teacher moves and norms of choice could support bilingual children's developing fractional understanding.

Keywords: Bilingual Learners, Fractional Mathematical Thinking, Problem Solving

Most research in special education on fractions with children identified with learning difficulties primarily emphasizes behaviorist models that focus on performance versus conceptual understanding (Lambert & Tan, 2020). Behaviorist studies typically emphasize pre- and post-assessments that capture children's knowledge at isolated points in time (e.g., Namkung & Fuchs, 2019), rather than examining their conceptual development longitudinally. Furthermore, many of these studies assume that the measured performance is inherently valid and free from bias. Performance-based research studies may have limited impact on advancing children's mathematical knowledge and, in some cases, could contribute to the marginalization of children of color by constraining opportunities for problem-solving learning (Lambert, 2015; Tan et al., 2022). Few of these studies have examined fractional interventions grounded in constructivist approaches such as teacher-responsive moves designed to support bilingual children's mathematical thinking (e.g., Lambert, 2015; Hunt et al., 2023; Silva et al., 2023). In this paper, we add to the literature by examining how a bilingual child with identified mathematics difficulties engaged with and constructed fractional knowledge. Our research question was: How did Julia, a child with identified mathematical difficulties, demonstrate her fractional thinking during problem-solving instruction when supported through responsive teacher moves and norms of choice?

Theoretical Framework

This study drew on Jacobs and Empson's (2016) framework of responsive teaching to support students' engagement in mathematical reasoning. Specifically, we incorporated eliciting (e.g., "I noticed you added four each time. Why did you do that?," clarifying (e.g., "What is the problem asking you to find?"), and extending (e.g., "What if there were five brownies instead of two? How would you share them?") prompts to support children in sharing their mathematical thinking in ways that were meaningful to them. Our norms were centered on choice and children's funds of knowledge (Silva, 2018, 2021). The sessions were designed to position children as sense-makers, with teacher support to help them exhibit mathematical agency. Children had opportunities to solve mathematical tasks using a strategy of their choice, share and represent their mathematical thinking in multiple ways, and communicate ideas in English or

Spanish while using gestures. Centering norms around choice helped humanize participation and broaden how children engaged in solving and discussing mathematical ideas. To investigate children's part-whole understandings of fractions, we utilized equal sharing tasks as described by Empson and Levi (2011). We identified equal sharing tasks as appropriate, as they are well documented in the literature as great entry points into children's fractional reasoning (Streefland, 1993). Consistent with Hunt and Empson (2015), we sought to document the development of children's fraction thinking over time.

Methods

This study took place at an elementary school in an urban city in the southwestern United States. The first author conducted and taught 12 lessons during small group instruction held within the school day. Three bilingual children participated in the small group, and each session lasted approximately one hour. Instruction occurred in a conference room equipped with a large table, manipulatives (i.e., unifix cubes), paper, pencils, and a whiteboard. This paper presents preliminary data on five problem-solving sessions on the mathematical thinking of one bilingual child, Julia (pseudonym). Julia was purposefully selected because she was a bilingual Latina third-grade student identified as an English Language Learner (ELL) and as having mathematics difficulties. Her mathematical difficulties were identified by the school through the response to intervention (RTI) model (Fuchs & Fuchs, 2007). Under this model, Julia was designated as Tier 3, indicating that she received intensive, individualized intervention. The assistant principal identified Julia as experiencing mathematics difficulties based on midyear and end-of-year mathematics benchmark assessments, and she was undergoing evaluation for a potential mathematics learning disability.

Our sessions were taught using a problem-solving model (Stein et al., 2008). Children were encouraged to solve problems using strategies that made sense to them; they were allowed to represent their mathematical strategies visually and verbally through Spanish or English, work individually or with partners, and share their ideas in ways that best supported their understanding.

Data Collection

To document Julia's mathematical thinking across sessions, we collected video recordings of each problem-solving session, her written work, and researcher-teacher field notes. Each video was transcribed verbatim, with attention to Julia's gestures, verbal explanations, and utterances. We analyzed video transcripts for her fractional reasoning, strategy drawings, and gestures to examine the development of her fractional partitioning strategies over time.

Analysis

To examine Julia's development of fractional understanding, we used retrospective analysis (Leech & Onwuegbuzie, 2007) to identify patterns of her mathematical ideas and conceptual growth across fractional tasks. We also employed content analysis (Saldaña, 2013) to identify and categorize the fraction strategies she used. The first author initially reviewed Julia's strategies from the first session using video recordings, transcripts, and written work. These data were then independently coded by the second author through analysis of the videos and transcripts. To identify and interpret Julia's fractional strategies, we drew on the initial codes established by Hunt and Empson (2015), which broadly characterize children's fractional strategies as non-coordination, non-anticipatory, and emergent anticipatory. We also developed additional partitioning codes to capture nuances within and across these categories (see Table 1 for final codes). All transcripts were transferred and analyzed using MAXQDA 2024 software, resulting in the identification of 10 analytic episodes across the five sessions. We defined

episodes as interactions in which Julia explored and discussed her fractional reasoning strategies during each equal-sharing task. Once the episodes were identified, we independently wrote analytic memos for each episode, addressing questions about what Julia's fraction understanding revealed and how she demonstrated her fractional thinking, while also noting changes across sessions. Next, we met to refine the initial codebook by collaboratively coding the first two episodes, revising and clarifying code definitions until we reached 100% agreement. We then coded the remaining episodes independently and subsequently met to discuss discrepancies and reach consensus. The final interrater agreement was approximately 96%.

Table 1: Fractional Codes of Partitioning

Category	Codes	Definitions of Codes
No Coordination	Partitioning leftovers by correspondence	Sees the whole as divisible. Links sharers to a plan for sharing after the fact (perhaps on final piece/pieces) as they distribute wholes items first and then see the need to partition leftovers. Child begins to partition leftover pieces by doubling/halving, but the partitioning seems ineffective for the child. Does not mind having additional pieces leftover and has remaining pieces that are not shared or the share for each person is not distributed equally.
No Coordination	Partitioning all wholes by half and leftovers by correspondence	Sees the whole as divisible. Child partitions all wholes by half, the remaining leftovers were partitions by correspondence. Child is bothered by having additional pieces leftover and or remaining pieces that are not shared or distributed equally among the sharers.
Non-Anticipatory	Partitioning all wholes by half and leftovers by number of sharers	Sees the whole as divisible. Partitioning all wholes by half, then the remaining leftovers were partitions by the number of sharers. Child seems to evidence an increased need for equal pieces through partitioning and distributes all the shares to sharers equally.
Non-Anticipatory	Partitioning leftovers by number of sharers	Sees the whole as divisible. Child links sharers to a plan for sharing after the fact (perhaps on the final pieces) as they distribute wholes items first and then see the need to partition leftovers. Uses number of sharers as a prior plan to partition leftover wholes. Child seems to evidence an increased need for equal pieces through partitioning and distributes all the shares to sharers equally.
Emergent Anticipatory	Partitioning all wholes by number of sharers	Links sharers to a plan for sharing before activity. She may use the number of sharers as a partitioning strategy for all the wholes (e.g., 5 share 3 cakes, says cut all 3 cakes into 5 pieces). The strategy was formed in activity with correspondence, yet its use becomes implicit as the child abstracts his/her activity.

Results

Julia made shifts within her fractional partitioning strategies. Initially, she relied on partitioning strategies by correspondence (see Table 2) and gradually transitioned to more complex strategies, including partitioning by the number of sharers. Julia adapted her strategies based on the type of representation and whether the share was greater than or less than one. When the share exceeded one, she first distributed a whole to each person and then partitioned the leftover pieces by the number of sharers. When the share was less than one, she began by partitioning the whole in half rather than dividing directly by the number of sharers. A particularly significant shift occurred between sessions nine and 12 (see Figure 1). In session

nine, Julia attempted to partition the leftovers by the number of sharers, though only after several attempts. By session 12, she consistently partitioned the leftovers by the number of sharers. Teacher questions to clarify and elicit mathematical thinking helped Julia reflect upon her strategies and carefully examine her partitioning strategies over time. Notably, in Session 11, Julia partitioned all wholes by the number of sharers rather than beginning by distributing whole pieces. When prompted to explain how many pieces she planned to make, Julia responded, "seven in each," indicating that she intended to create seven parts per candy bar before she enacted her strategy. This marked an important developmental shift, as her approach was beginning to be pre-planned and demonstrated an emergent anticipatory strategy for the first time.

Table 2: Julia's Fractional Strategies

Session	Task	Partitioning Strategy Code	Fractional Code
8	8 chocolate bars shared equally among 3 kids	Partitioning leftovers by correspondence	No-coordination
9	3 cakes shared equally among 5 kids	Partitioning all pieces by half, partitions leftovers by correspondence	No-coordination
10	10 cookies shared equally among 4 kids	Partitioning leftovers by number of sharers	Non-anticipatory
11	11 candies shared equally among 7 kids	Partitioning all wholes by number of sharers	Emergent-anticipatory
12	4 brownies shared equally among 6 kids	Partitioning all pieces by half, partitions leftovers by number of sharers	Non-anticipatory

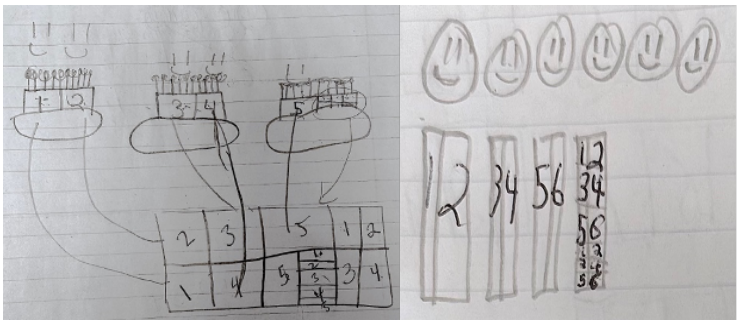

Figure 1: Julia's Written Solutions to Session 9 (right) and 12 (left)

Conclusion

Mathematics and special education teachers who work with bilingual children should critically examine their problem-solving instruction. Instruction that focuses only on standardized testing and rigid curricula reduces creativity and curiosity. In contrast, participating in mathematical teacher practices supports children's conceptual development and increases understanding in the classroom (Bodovski & Farkas, 2007). The current study examined how responsive teaching and problem-solving instruction using equal sharing tasks can help foster a bilingual child's understanding of fractions. This study demonstrates the crucial role of teacher responsive moves in enhancing students' mathematical thinking of fractions during problem-solving. Moreover, it shows the importance that teaching norms of choice can shape bilingual students' opportunities to execute problem-solving strategies that develop deeper understanding

of mathematical concepts. This study illustrates how future studies of bilingual children with math difficulties can participate and learn fraction concepts during problem-solving instruction.

FACTORS CONTRIBUTING TO UNDERGRADUATE STUDENTS' DISLIKE OF SCHOOL MATHEMATICS

Amrit Bahadur Thapa
Eastern New Mexico University
amrit.thapa@enmu.edu

This qualitative study examines undergraduate students' reflections on their school mathematics experiences and the development of their dislike of mathematics. Fifteen undergraduates enrolled in a college Quantitative Reasoning (QR) course at a midsize university in the Midwestern United States participated in the study. Participants were purposefully selected based on their self-reported dislike of mathematics. Semi-structured interviews conducted at the beginning of the semester were transcribed, coded using NVivo, and thematically analyzed. Findings identified six factors contributing to students' dislike of school mathematics: irrelevant content, poor instructor-student relationships and support, inflexible assessment practices, learning disabilities, parental pressure, and media influence.

Keywords: Dislike of School Mathematics, Factors Contributing to Dislike of Mathematics, Attitude Toward Mathematics

Purpose of Study

Dislike of mathematics is expressed in emotional, psychological, and social forms that can lead individuals to distance themselves from mathematics and its application in both academic and everyday life (Thapa, 2016). Aguilar (2021) explored high school students' dislike of mathematics, identifying factors that contribute to its development. News media have also reported widespread dislike of mathematics. For example, Cook (2015), in *U.S. News*, highlighted research on young students' disinterest in mathematics that often extends into high school. Similarly, a *Washington Post* article (2016) described math anxiety as a cultural phenomenon, and Strauss (2011) argued that the issue stems less from ineffective teachers and more from the content taught in mathematics classrooms. This widespread dislike affects not only academic performance (Wachsmuth et al., 2017) but also students' personal and professional development. Dislike of mathematics can lead to avoidance, reduced confidence, and limited participation in mathematics-intensive fields (Ernest, 2016). Therefore, addressing dislike of mathematics requires identifying its root causes—including teaching practices, curriculum content, and societal influences (Sam & Ernest, 2000; Taylor, 1996; Levy-Warren, 2017). Accordingly, this study is guided by the following research question: What are undergraduate students' perspectives on the factors that contribute to their dislike of school mathematics?

Literature Review

The word *like* is a transitive verb, defined by the Merriam-Webster dictionary (n.d.) as "to feel attraction toward or take pleasure in" (para 1). In mathematics, liking mathematics means that a student is attracted to or takes pleasure in learning it, whereas disliking reflects the opposite. These responses are shaped by students' experiences and environments (De Houwer & Hughes, 2020) and represent stable affective responses rather than temporary emotions (McLeod, 1992).

Attitudes toward mathematics consist of beliefs about oneself and mathematics, together with emotions associated with the subject (Di Martino & Zan, 2010). Self-concept refers to an

individual's beliefs about their ability to handle a situation (Skaalvik & Skaalvik, 2006), while positive self-concept and self-efficacy support achievement and performance (Van der Beek et al., 2017; Liu & Koirala, 2009).

Mathematics is often portrayed as abstract, rigid, and accessible only to a few, shaping students' identities, engagement, and sense of belonging (Ernest, 2003, 2016; Sam & Ernest, 2000). Students' liking or disliking of mathematics is also influenced by aptitude, instruction, and the social-psychological environment (Mzomwe et al., 2019).

Mathematics anxiety, characterized by fear and tension during mathematical tasks (Field et al., 2019), is associated with lower performance, reduced engagement, and avoidance (Núñez-Peña et al., 2013; Liu & Koirala, 2009). It disrupts cognitive processing (Ashcraft, 2002) and is influenced by classroom practices emphasizing speed, correctness, and evaluation, as well as teachers' own anxieties (Finlayson, 2014; Pieronkiewicz, 2017; Bates et al., 2013; Swars et al., 2006).

Negative attitudes can emerge in elementary school and are linked to viewing mathematics as procedural and evaluative (Larkin & Jorgensen, 2016; Di Martino & Zan, 2010). Teaching mathematics as a process rather than a product may reduce these negative dispositions (Hannula, 2012).

Although research documents students' dislike of mathematics, fewer studies examine students' perspectives on why they dislike mathematics. This study addresses that gap by exploring student perspectives on their experience with learning school mathematics and identifying factors that contributed to their dislike of mathematics.

Methodology

Qualitative research is particularly well-suited for studies involving subjective and in-depth exploration of human perspectives of their lived experience (Wilson, 2015); this approach enables a deeper understanding of complex and dynamic variables (Denzin & Lincoln, 2018; Leavy, 2020), making it appropriate for this study, which explores students' reflections on their school mathematics learning experiences and the development of their dislike of mathematics. Fifteen undergraduate students enrolled in a college-level quantitative reasoning course at a mid-sized university in the Midwestern United States in Spring 2023 participated in the study. Six of the seven sections of the QR course were invited to participate in the study. The seventh section was excluded because it was taught by the principal researcher, thereby minimizing the potential for researcher bias and perceived coercion (Creswell & Poth, 2018). The QR class was purposefully selected as this was a foundational general education course, and generally, students in non-math majors and with math aversion enrolled in it (Hennrich & Lee, 2011; Foley et al., 2023). Participants were selected based on their self-reported dislike of school mathematics and were 18 years of age or older. Each participant completed a semi-structured interview lasting approximately one hour at the beginning of the semester. The semi-structured format allowed flexibility in participants' responses (Merriam & Tisdell, 2015). Participants were given the option of in-person or virtual interviews, and the interviews were audio- and audio-video-recorded, then transcribed and coded using NVivo software.

To ensure quality and rigor, I employed thick description, peer debriefing, member checking, pseudonyms, verbatim participant quotes, and thematic saturation to support confidentiality, trustworthiness, credibility, and transferability (Patton, 2015; Brinkmann & Kvale, 2015).

Findings

Factors Contributing to Dislike of Mathematics

The findings identified six factors contributing to students' dislike of mathematics: irrelevant content, poor instructor-student relationships and support, inflexible assessment practices, learning disabilities, parental pressure, and media influence. Of these, the first three factors appeared most frequently across interviews, whereas the remaining three were mentioned by fewer participants.

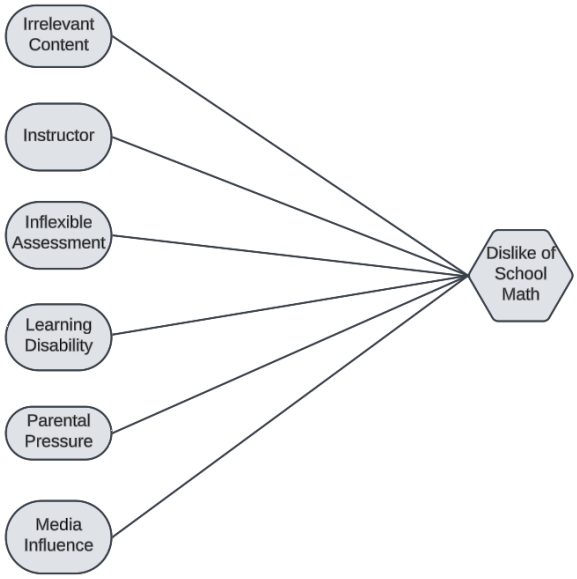

Figure 1: Factors Contributing to Dislike of Mathematics

Lack of real-world connection and relevance. Most students expressed a lack of interest in mathematics because the content and the way it was taught were not relevant to or connected with the real world. Some students stated, "*I don't recall any real-world connections in those classes.*" Another student commented, "*I know in school you never really learned much about how things are taxed. I feel like if there was a way for it to benefit my future, then I think that would have helped me a lot.*" A third student remarked, "*If the course content involved real-life units, questions, and examples, it makes a lot more sense to me. And I would enjoy doing those a lot more than random formulas that I don't even know if I'll personally use.*"

Lack of student-centered teaching and support. Most students expressed dissatisfaction with teacher-centered approaches focusing primarily on textbooks. One participant said, "*She would just pass out the papers at the beginning of class. And have you turned them in by the end? There was no personal connection, no walk-through, or anything. … I thought it was awful.*" Another participant said, "*It was mostly because there wasn't a very good teacher-student connection. … And, so, I didn't really like to ask questions. And, so, that made me kind of fall behind.*" A third participant said, "*He just has the reputation because he just does not work with kids. He's just like a straight, intimidating guy.*" And a fourth participant said, "*There have been instances where I would ask my teachers for help, and they wouldn't be very nice about it, or they wouldn't really have anything to offer me.*"

Inflexible assessment practices. Most participants expressed that inflexible assessment practices contributed to their struggle with mathematics and dislike of it. More specifically, they highlighted the timed exams and the exams focused on memorization of facts from texts, causing anxiety and fear. One participant said, "*There were a couple of times where I was like just so nervous for a math test that I would have to leave the room and go to the nurse's office. ... the thought of failing a test was terrifying*." Another participant said, "*I think a lot of the anxiety does come from one being timed … that was my biggest downfall was it was timed*." A third participant said, "*Definitely to every single math test. … I would never go in like super confident … it was painful going through a math test*."

Learning disabilities, parental pressure, and media influence. Out of the 15 participants, six mentioned that they had some form of learning disability, such as ADHD, dyscalculia, or dyslexia. For many, these disabilities were identified only later, and even then, their schools provided little support beyond extending due dates or providing extra time. For example, one participant said, "*Typically, to get additional time, I'd have to have some sort of medical documentation … And I didn't realize I had any sort of learning disability or something that would affect my learning until I was in 12th grade.*"

Similarly, some students recalled parental pressure. Although their parents encouraged them and intended to be supportive, many were unable to provide adequate academic or other support. As one participant explained, "*They definitely pushed me a lot. I did tutoring sessions outside of school for math specifically. And, I had to do online courses at some point. … It definitely made me hate it more.*"

Likewise, some participants recalled that media influenced their self-concept of mathematics ability and perceptions of mathematics, with cartoon programs and other social media reinforcing negative beliefs. For example, one participant said, "*social media or stuff like that kind of feeds into the hatred of math. It's just seeing so many other students who might also hate math talk about their hate of math … you'll be like, 'Oh, I hate it too.*'"

Discussion and Conclusions

The findings indicate that students' dislike of mathematics begins early, often in elementary grades, when foundational concepts are taught in rushed, textbook-centered, and procedural ways without meaningful real-world connections. As students progress, abstract content, fast-paced instruction, and heavy reliance on timed, standardized assessments intensify anxiety, avoidance, and negative self-concept. Learning disabilities, insufficient accommodations, parental pressure, and negative media messages further compound these experiences. Students consistently reported low enjoyment, limited perceived utility, minimal motivation, and poor performance in school mathematics, reinforcing students' dislike of mathematics.

The transition from arithmetic to algebra is often hindered by a reliance on whole-number rules that "expire" in secondary mathematics. Paralleling the early algebra movement, we push for a similar early integer movement. This theoretical research report centers on the integer principles for addition and subtraction, a framework designed to expand K–5 numerical understandings toward the signed number system. By prioritizing symbolic flexibility, absolute and linear value, and translation models, the framework establishes a robust foundation for algebraic success. Establishing these principles early ensures mathematical coherence across number domains. Ultimately, this work reimagines learning progressions to foster the numerical, symbolic, and operational foundation required for advanced mathematics, like algebra.

Keywords: Algebra and Algebraic Thinking, Elementary School Education, Number Concepts and Operations

Algebra remains a significant gatekeeper to advanced mathematics and STEM careers (e.g., Barroso, 2020; Herscovics & Linchevski 1994; Kieran, 1992), leading to a broad consensus that students require earlier access to algebraic thinking (National Mathematics Advisory Panel, 2008; Moses & Cobb, 2001). The early algebra movement successfully addressed earlier access by promoting developmentally appropriate preparation in the early grades, such as shifting student understanding of the equal sign from an operational to a relational view (Blanton et al., 2007; Cai & Knuth, 2005). However, while students are becoming better equipped for algebraic generalization, a significant hurdle remains: the transition from the restricted domain of whole numbers to the broader system of integers (e.g., Bishop et al., 2014; Vlassis, 2004, 2008).

Despite the successes of early algebra, accounts of student struggle with the "arithmetic-to-algebra" transition remain plentiful (e.g., Cao et al., 2025; Barroso, 2020). This difficulty is due, in part, to a foundational reliance on whole-number rules that prove insufficient when negative integers surface in secondary mathematics (Bofferding, 2014; Karp et al., 2014). In traditional K-5 curricula, students are immersed in a whole-number-only environment that reinforces procedural rules that expire. For example, procedural shortcuts like "you cannot subtract a larger number from a smaller one" or "subtraction always makes a number smaller" (Karp et al., 2014) are not true from the transition from whole numbers to integers. While these are localized truths for positive whole numbers (or natural numbers), they create a limited understand of number that leads to immediate frustration and a decreased sense of competence when students encounter integers in middle school (e.g., National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010; Vlassis, 2004).

To mitigate these difficulties, mathematics education must pivot toward a robust framework that exposes negative integers to students in the early grades. Students need the conceptual tools to move beyond binary operations toward the multiple meanings of the minus sign, like interpreting it as a unary sign and a directed distance (Vlassis, 2008). Without this foundation, structural misconceptions persist into algebra; for example, students often incorrectly extend commutativity to subtraction, transforming $a - x = b$ into $x - a = b$ (Gallardo & Rojano, 1994).

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

By shifting focus from procedural shortcuts to the underlying structures of the number system—including the symmetry of the number line (e.g., Tsang et al., 2015) and directed distance—we can better prepare students to interpret addition and subtraction flexibly across all algebraic situations.

An Argument for Early Integer Introduction

The early algebra movement gained traction by arguing that integrating algebraic thinking in elementary school, rather than treating it as a separate post-arithmetic stage, is a key factor for later success (Katz, 2007; Gardiner et al., 2016). Just as early algebra focuses on promoting generalizations and noticing structures like the identity and inverse properties (Blanton et al., 2007; Cai & Knuth, 2005), an early integer approach allows students to notice the structure of the number system, rather than as a series of disconnected rules. Previous accounts illustrate that even children in kindergarten and first grade can productively reason about negative numbers (Aze, 1989; Behrend & Mohs, 2005–2006; Bofferding, 2014; Wilcox, 2008). Therefore, we argue against a strictly linear "whole numbers-then-integers" approach in favor of appropriately integrating integers into the early grades and reimagining learning progressions to promote mathematical coherence.

The goal is not to push secondary curriculum down, but to further prepare students for algebraic thinking in developmentally appropriate ways (Blanton et al., 2007). How can we introduce negative integers in developmentally appropriate ways? One way may be by introducing integers through playful mediums like number talks or games. These mediums should provide students with opportunities to explore negative integer principles, such as understanding the meanings of opposite or that the commutative property works for addition, but not subtraction, within a conceptually oriented and accessible framework (Bruner, 1963; Wessman-Enzinger & Bofferding, 2014). This early exposure ensures that when students eventually encounter algebra, they are not "unlearning" whole-number principles, but are instead extending a robust, coherent understanding of the number system. We acknowledge that similar issues may exist with the transition from whole numbers to rational numbers, but we restrict our focus here to integers. Before numerical learning progressions are reimagined or games are designed to incorporate integers, we first need to envision the types of number principles that are affected by expansion of experiencing mathematics with only whole numbers to mathematics that include negative integers.

The Integer Principles

We present the idea of the *integer principles* as a framework for thinking about what expanding the number system from whole number to negative integers in elementary schools might entail. The integer principles are the mathematical generalizations that allow for a coherent understanding of the signed number system. They extend whole-number reasoning by introducing the concepts of directionality, symmetry, and additive inverses, ensuring that mathematical rules remain consistent across all real numbers. Table 1 details whole number principles compared to integer principles. The whole number principles are ways children may conceptualize numbers if limited to only positive integers, or whole numbers. The integer principles are ways children may conceptualize numbers if their number system is expanded beyond positive integers to negative integers.

Table 1: Whole Number Principles Compared to Integer Principles

	Whole Number Principles	Integer Principles
A	Numbers are represented by numerals. Addition is represented by the plus sign. Subtraction is represented by the minus sign.	Numbers are represented by numerals and signs. The plus sign can designate an addition or a positive number. The minus sign can designate subtraction, negative, or opposite (Vlassis, 2004).
B	Numbers can be ordered by their position in the count list [starting at 0 or 1] (Steffe, 1983; Vosniadou et al., 2008).	Numbers exist on both sides of zero (Bishop et al., 2016). Numbers can be ordered by their position *and* direction from zero (Russo, 2019; Schindler & Huβmann, 2013).
C	Numbers can be embodied naturally with physical objects (Schindler & Huβmann, 2013).	Negative numbers can only be embodied abstractly with physical objects (e.g., mapping -1 or +1 to a chip; Lakoff & Nuñez, 2000; Martínez, 2006); they are relative numbers (Gallardo, 2002).
D	Numbers further from zero have larger values (Vosniadou et al., 2008).	Numbers have absolute values (numbers further from zero have larger absolute values) and linear values (positive > negative, and negative numbers closer to zero have larger linear values than negative numbers further from zero (Ball, 1993; Bofferding, 2014; Wessman-Enzinger, 2018).
E	Numbers can be decomposed into numbers with smaller values.	Numbers can be decomposed into infinite combinations of numbers that could include numbers with larger values than themselves.
F	Adding or subtracting zero does not change the value *(Identity with Addition and Subtraction)*.	Adding or subtracting zero does not change the absolute or linear value *(Identity with Addition and Subtraction)*.
G	Adding can be done on numbers in any order and still have the same answer *(Commutative Property*).	Adding numbers can be done in any order and still have the same answer *(Commutative Property*), but switching numbers in subtraction leads to different answers (3 – 2 = 1; 2 – 3 = -1, *Non-commutative Property*, Bofferding, 2010).
H	Subtracting a number from itself equals zero *(Subtracting Same*). Subtraction starts with the bigger number (Karp et al., 2014).	Subtracting a number from itself equals zero *(Subtracting Same)*. Adding a number to its inverse equals zero (*Additive Inverse*, Dickman & Bofferding, 2016-2017).

I	Addition results in bigger values (Karp et al., 2014; Vosniadou et al., 2008). Subtraction results in smaller values (Karp et al., 2014; Vosniadou et al., 2008).	Addition results in absolute and linear values that are either smaller or bigger than the original value. Subtraction results in absolute and linear values that are either smaller or bigger than the original value.
J	Adding can be represented as a translation to the right on a number line. Subtracting can be represented as a translation to the left on a number line.	Adding can be represented as a translation to the right or left on a number line (i.e., a movement more positive or more negative). Subtracting can be represented as a translation to the left or right on a number line (i.e., a movement less positive or less negative; Bofferding & Farmer, 2019; Marthe, 1979; Selter et al., 2012; Wessman-Enzinger, 2019; Wessman-Enzinger & Tobias, 2020).
K	The sum of two translations is a longer translation. Subtraction can be represented as the difference or distance between two states.	The sum of two translations is the directed distance from zero to the final position of the translation. Subtraction can be the directed difference or directed distance between two states (Marthe, 1979; Wessman-Enzinger, 2019; Wessman-Enzinger & Tobias, 2020).

The integer principles summarized in Table 1 are the fundamental structures that could naturally evolve from the whole numbers in developmentally appropriate ways during the elementary years and also provide insight into future instructional or game design. The integer principles represent the conceptual extension a student must make to move beyond "counting objects" to "imagining number beyond zero" (Bishop et al., 2016; Wessman-Enzinger, 2025). Next, we dig into the integer principles more.

Symbolic and Structural Principles (Principles A, B, C)

Principles A, B, and C (see Table 1) define what a number is and how it is represented. Principle A directly addresses the multi-faceted use of the negative sign. In a whole-number world, a minus sign only means "take away." With negative integers, it can be a binary operation (subtraction), a unary sign (negative), or a relational direction (opposite) (Vlassis, 2004, 2008). Principles B and C highlight that numbers are relative and can be placed with symmetry around zero on a number line (Russo, 2019; Schindler & Huβerman, 2013; Tsang et al., 2015). Zero is no longer just "nothing" or the starting point; it is the center of a system where number exist in two directions (e.g., Bofferding, 2019; Vosniadou et al., 2008).

Symbolic and structural principles parallel to the early algebra movement. Just as the early algebra research rejects the idea that students must master all of arithmetic before being introduced to algebraic structures, an early integer approach rejects the traditional linear progression that delays negative numbers until middle school. By introducing integer principles in the early grades, we provide a "structural" rather than a "computational" foundation, mirroring how early algebra encourages students to see the equal sign as a symbol of equivalence rather than a command to compute (Knuth et al., 2006). In both movements, the goal is not to accelerate secondary content into the elementary classroom, but to foster an early habit of mind that prioritizes mathematical generalizations and the identification of underlying structures (Cai & Knuth, 2011).

Symbolic and structural principles' impact on algebraic thinking and learning. Establishing these integer principles early makes a profound difference in a student's ability to navigate the formal abstractions of algebra. When students transition to algebra without a robust understanding of directed numbers, they often treat variables as "whole number placeholders," leading to significant errors when those variables take on negative values (Gallardo & Rojano, 1994). By mastering the multi-faceted use of the minus sign (Principle A) and the symmetry of the number line (Principles B and C) early on, students develop the "symbolic flexibility" required to manipulate algebraic expressions where signs are relational rather than just operational (Vlassis, 2008). Ultimately, this early conceptual expansion ensures that the "rules" of mathematics remain coherent; students are not forced to unlearn whole-number restricted reasoning but are instead prepared to apply generalized principles to the abstract landscapes of functions and equations.

Order and Value Principles (Principles D, E, I)

Principles D, E, and I (see Table 1) redefine how we determine which number is "larger" or "smaller." Specifically, these integer principles introduce the idea that a number has two types of value: absolute value and linear value. When students compare only positive integers, or whole numbers, linear and absolute value are the same so distinguishing between them is unnecessary (Vosniadou et al., 2008**)**. Absolute value (distance from zero) and its linear value (its relative position from left to right on a number line) do matter when the concept of number is extended beyond positive numbers to include negative integers (Ball, 1993; Bofferding, 2014; Wessman-Enzinger, 2018). This explains why –10 is "larger" in absolute value than –2, but "smaller" in its linear value. These principles also highlight that numbers can be broken down into an infinite combination of others, including numbers larger than themselves (e.g., $2 = 5 + -3$).

Order and value principles parallel to the early algebra movement. The distinction between absolute and linear value mirrors a core tenet of the early algebra movement: the shift from viewing mathematics as a series of discrete computations to a study of relationships and structures. Early algebra research argues that students must move beyond "arithmetic" results to understand the underlying properties of numbers (Blanton et al., 2011; Kaput, 2008). Similarly, introducing the dual nature of number values—where a number's distance from zero is distinct from its relative position—mirrors how early algebraists teach the equal sign as a relational symbol of balance rather than a signal to calculate (Knuth et al., 2006). In both cases, the goal is to expand the student's mathematical ontology. Just as early algebra avoids the "arithmetic-then-algebra" trap by integrating structural thinking early (Gardiner et al., 2016), introducing the absolute-value (or magnitude) distinction in the elementary grades prevents students from becoming tethered to the whole-number misconception that "larger" always means "further from zero" or always means "further to the right."

Order and value principles' impact on algebraic thinking and learning. Mastering these order and value principles is essential for developing the numerical flexibility required to handle algebraic variables and inequalities. When students do not distinguish between absolute and linear value, they struggle to conceptualize expressions like $|x| > 5$, often failing to realize that a "smaller" linear value (such as –10) can possess a "larger" absolute value (Ball, 1993; Wessman-Enzinger, 2018). Knowing that integers have these two types of values and can be decomposed into infinite combinations is a direct prerequisite for algebraic manipulation and working with equations. This conceptual shift allows students to view integers as vectors or directed distances rather than just as counting numbers. Without this foundation, students often perceive algebra as

a collection of arbitrary "tricks;" but with it, they gain a coherent system for thinking that allows them to predict and verify the behavior of negative terms in complex equations.

Operational Principles (Principles F, G, H, I)

Principles F, G, H, and I (see Table 1) reimagine how addition and subtraction are defined when negative integers extend a prior number system with only whole numbers. A notable example of this is the non-commutative nature of subtraction. Addition is commutative (e.g., $5 + -2 = -2 + 5$), and when students only operate with positive integers, they extend the commutative property (e.g., $5 + 2 = 2 + 5$) to subtraction, which does not hold. The integer principles solidify that subtraction is not commutative. Reversing the order of numbers within subtraction results in the additive inverse (e.g., $5 - 3 = 2$, but $3 - 5 = -2$). When using only whole numbers, addition always increases value. Yet, when using negative integers, adding a negative decreases linear value, and subtracting a negative increases it (Karp et al., 2014; Vosniadou et al., 2008).

Operational principles parallel to the early algebra movement. This redefinition of operations mirrors the early algebra movement's emphasis on helping students notice and generalize mathematical structures, such as the identity and inverse properties (Blanton et al., 2007; Cai & Knuth, 2005). The early algebra movement argues that arithmetic should be taught as a way for exploring these properties rather than just as a method for finding answers. Similarly, an early focus on operational integer principles moves students away from computing a result toward understanding an operation. Just as early algebraists teach that the equal sign represents a relationship of balance, these integer principles teach that operations like subtraction represent a specific relationship between two points on a directed number line (Gardiner et al., 2016). By rejecting a "whole numbers-then-integers" approach, we align with the early algebra rejection of "arithmetic-then-algebra," fostering a unified understanding of how operations behave across all numerical domains.

Operational principles' impact on algebraic thinking and learning. Establishing these operational principles early prevents the cognitive shock students often experience when they first encounter algebraic expressions containing negative terms. In algebra, students must frequently manipulate expressions where they must distinguish between the minus sign as an operator and as a sign of the number (Vlassis, 2004). If students have already mastered the principle of the additive inverse and the non-commutative nature of subtraction, they are far less likely to make common algebraic errors, such as incorrectly rearranging $a - b$ as $b - a$ (Gallardo & Rojano, 1994). Furthermore, understanding that adding numbers can result in numbers with a smaller value prepares students for the conceptual demands of combining like terms and solving linear equations. This foundation transforms algebra from a series of counter-intuitive rules into a logical extension of a robust, pre-existing numerical system.

Translation Principles (Principles J, K)

Principles J and K (see Table 1) redefine how numbers are conceptualized through addition and subtraction (often on a number line). Subtraction is not just "taking away" objects or "removing" something but can be seen as a translation or directed distance between two points (Marthe, 1979; Wessman-Enzinger, 2019). Addition no longer means "move right." It means translating a specific direction based on the sign of the integer (Bofferding & Farmer, 2019; Wessman-Enzinger & Tobias, 2020).

Translation principles parallel to the early algebra movement. This shift from a counting model to a translation model parallels the early algebra movement's focus on promoting mathematical coherence through visualization and spatial reasoning (e.g., Blanton et al., 2007;

Pinialla, 2024; Venkat et al., 2020). Early algebra research emphasizes that students must move beyond the computational view of the number line to a structural view, where they can notice patterns and generalize properties (Blanton et al., 2007). Just as early algebraists use number lines and balance scales to represent algebraic equivalence visually (Knuth et al., 2006), these translation principles use the number line as a geometric tool to represent signed numbers. By introducing these translations in the early grades, we provide students with a spatial "map" of mathematics that mirrors the early algebra goal of preparing students for algebraic thinking in developmentally appropriate, conceptually-oriented ways (Cai & Knuth, 2011).

Translation principles' impact on algebraic thinking and learning. Mastering translation principles provides the vital scaffolding needed for students to grasp the concept of vectors and slope in secondary mathematics. When students view numbers as translations rather than just static quantities, they are better prepared to understand algebraic functions as transformations. For example, the concept of a directed distance is essential when students begin graphing linear equations or calculating the difference between two variables in the form of $x_2 - x_1$. Without this translational foundation, students often struggle with the negative space of a coordinate plane (e.g., Kieran, 2007; Sarama & Clements, 2009; Skordoullis et al., 2009); however, students who have explored these principles in elementary school develop a robust mental model that accommodates both positive and negative movement (Wessman-Enzinger & Tobias, 2020). This spatial fluency reduces the cognitive load during algebra, allowing students to focus on solving complex equations rather than struggling to navigate the directionality of the number system.

Future Directions for Research and Teaching

The integer principles framework serves as a roadmap for reimagining for both instructional design and pedagogical research in the elementary grades. For teachers, this matters because it provides a language to move beyond procedural tips toward structural mathematics. For example, instead of teaching students that subtraction always results in a smaller value, educators can facilitate explorations of directed distance and linear value. For researchers, this framework opens new avenues to investigate the longitudinal impact of early integer exposure on students' later success in formal algebra. Future studies should examine how specific playful mediums, such as the design of integer-based board games or targeted number talks, can be used to explicitly highlight these principles. By focusing research on how children navigate the transition from counting objects to directed quantities, the field can continue to refine learning progressions that prevent the development of deep-seated misconceptions before they take root.

Concluding Remarks

Mathematical success should not be a matter of unlearning whole number rules that expire (Karp et al., 2014) but should be the result of a coherent, cumulative expansion of mathematical understanding. By introducing the integer principles in the early grades, we provide students with a robust numerical foundation that remains consistent as they progress into more abstract domains. This shift from a whole-number-only approach to a generalized system of signed numbers addresses the persistent "arithmetic-to-algebra" hurdle by fostering symbolic flexibility and spatial reasoning from the start. As the early algebra movement has successfully argued for the integration of algebraic thinking into elementary school, so too must we advocate for the integration of the full integer system. In doing so, we move toward a mathematics education that is conceptually oriented, developmentally appropriate, and (most importantly) mathematically coherent.

WHEN RIGHT IS WRONG: MISAPPLIED PROCEDURAL PATTERNS THAT PRODUCE CORRECT ANSWERS IN FRACTION ARITHMETIC

Proficiency with fractions is essential for learning more advanced mathematical skills, such as algebra (Booth & Newton, 2012). However, developing a solid understanding of fractions has been a challenge for many students, especially students with mathematics difficulties (Newton et al., 2014). The present study examined how students with MD sometimes apply incorrect fraction arithmetic procedures in ways that still produce correct answers.

The following research questions guided our study: 1) What misapplied procedural patterns result in correct answers when sixth-grade students with MD solve fraction addition, subtraction, and multiplication problems? 2) What percentages of students used each of the identified procedural patterns?

Procedural and conceptual knowledge exist along a continuum and are often intertwined, yet the two ends represent different forms of understanding (Rittle-Johnson et al., 2001). Students often experience difficulties in solving mathematics not just because of limited knowledge, but because of a disconnect between their conceptual understanding and procedural skills (Hiebert & Wearne, 2013).

The present data are from a larger study assessing the effectiveness of a fraction intervention for sixth-grade students ($N = 251$) with MD. The students performed at least two years below grade level in mathematics. We used a deductive coding approach to analyze students' procedures (Braun & Clarke, 2006). Students' assessment booklets were coded to determine the strategies they used in solving the fraction arithmetic problems. The assessment was researcher-designed with an internal reliability of $\alpha = .79$.

Overall, our study revealed that sixth-grade students with MD often followed a misapplied procedural pattern when solving fraction arithmetic problems, which sometimes produced the correct answers for some of the fraction arithmetic problems. For instance, cross-operating produced the correct answer for $1/2 + 1/2 = 3/3 = 1$. Furthermore, these students tend to misapply procedures without considering the sensibility of their answers. Approximately 64% of the students operated across both the numerators and denominators when solving fraction addition, subtraction, and multiplication problems with unlike denominators. Although operating across the numerators and denominators is the correct procedure for fraction multiplication, but the students extended this same procedure to fraction addition and subtraction problems.

These findings show that correct answers do not necessarily reflect correct application of standard fraction procedures. By examining students' written work, teachers can identify instances where students are overgeneralizing procedures and provide instruction that emphasizes conceptual understanding in addition to procedural accuracy to better support students with MD in making sense of fraction concepts.

LLC VS NON-LLC STUDENTS' RESILIENCY, BELONGING, AND CONFIDENCE WHILE LEARNING AN UNDERGRADUATE MATHEMATICS COURSE

Harman Aryal

Stockton University
michael.slaza@stockton.edu

Student success in foundational mathematics remains a persistent challenge, particularly for first year college students who are academically underprepared. Living and Learning Communities (LLCs) purposefully integrate academic coursework with residential life to promote engagement and holistic student development; however, despite documented benefits across disciplines (Spanierman et al., 2013), LLC's impact within foundational mathematics courses and first-year experience programs remains underexamined. This gap is significant: academically underprepared students enrolled in developmental or foundational mathematics courses are especially vulnerable to attrition, and understanding how residential-academic structures may mediate their confidence, resilience, and belonging carries direct implications for retention and institutional practice. This study addresses the research question: *How do the perceptions and lived experiences of LLC students differ from those of non-LLC students while learning a Mathematical Thinking course?*

A qualitative multiple-case study design (Yin, 2018) was used to explore the experiences of first-year LLC and non-LLC students taking Mathematical Thinking course in Fall 2025. Both sections were taught by the same instructor with no instructional intervention. Seventeen students (eight LLC, nine Non-LLC) completed three surveys—the Math Confidence (Hendy et al., 2014), the Academic Resilience ARS-30 (Cassidy, 2016), and Sense of Belonging Scale Hoffman et al.'s (2002) Sense of Belonging—and composite scores were used to identify interview participants across low, moderate, and high ranges. Twelve students participated in 30-minute semistructured interviews conducted in person or via Zoom. Data were analyzed using thematic analysis (Braun & Clarke, 2006; Merriam & Tisdell, 2016), incorporating open coding and cross-case analysis to identify convergent and divergent patterns between groups.

Cross-case analysis showed four thematic patterns. First, regarding *peer collaboration*, LLC students described peers as actively involved in learning—"Somebody else in the group would teach them, and I think that's the good part about it"—while non-LLC students emphasized independent study: "I mostly just do it on my own." Second, concerning *instructor support*, LLC participants used relational and affective language ("It gave me belief in myself"), whereas non-LLC participants referenced instructors primarily in the context of academic difficulty. Third, with respect to *classroom participation*, LLC students expressed comfort with intellectual risk ("I feel like I can be wrong, and it's okay"), while non-LLC students tied participation to certainty ("I would only participate if I knew what I was learning"). Fourth, in *responses to academic difficulty*, LLC students described structured review and peer-supported coping, while non-LLC students described individualized coping without collaborative support.

These findings suggest that LLC creates a supportive sociocultural environment that may enhance belonging, resilience, and mathematics confidence. Collaborative engagement and relational instructor support among LLC students align with sociocultural learning theory and belonging research (Walton & Cohen, 2007), while non-LLC environment reflects more individualized learning. These results extend the LLC literature into foundational mathematics education and offer implications for designing high-impact first-year programs that integrate residential and academic structures to support underprepared students' mathematical success.

YOUTH INSIGHTS INTO NARRATIVES ABOUT THE USEFULNESS OF MATHEMATICS

Tracy E. Dobie
University of Utah
tracy.dobie@utah.edu

Bailey N. Ondricek
University of Utah
bailey.ondricek@utah.edu

Liza Escobar Aquino
University of Utah
liza.escobar@utah.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Middle School Education

Youth frequently question the usefulness of mathematics, and prior research has illustrated a range of benefits of perceiving mathematics as useful (e.g., Hulleman et al., 2010). And yet, the voices of early adolescents are typically not represented in this research despite middle school being a time during which attitudes towards mathematics often decline and youth frequently question the usefulness of mathematics (e.g., Dobie, 2019). Adults often offer perspectives that align with common narratives about mathematical utility—e.g., for getting a job or making our country more globally competitive (e.g., The President's Council of Advisors on Science and Technology [PCAST], 2010). Questions remain about youth perceptions of these narratives and potential disconnects with their own values (Dobie, 2019). Guided by expectancy-value theory (Eccles & Wigfield, 2002), research on adolescents' prosocial values (e.g., Eisenberg et al., 2009), and emphases on connectedness and harmonious relationships in Hispanic/Latine cultures (Ruiz, 2005), this study asks, "How do early adolescents perceive common individualistic and relational narratives about the usefulness of mathematics?"

Solo or pair interviews with 17 youth ages 12–15 (majority Hispanic/Latine) were conducted in after-school programs in the Mountain West. Interviews involved a card-sorting task in which youth were presented with narratives about the usefulness of mathematics and asked to explain whether and why they agreed or disagreed with each statement (see Table 1 for statements and frequencies of agreement). Inductive and deductive approaches (Fine, 2004) were used to develop a coding scheme to identify applications of mathematics emphasized by youth (e.g., money, jobs, school). Two coders coded all verbal responses and resolved any disagreements.

Table 1: Youth Agreement with Narratives About Mathematical Utility

	Agree	Unsure	Disagree
You will need math so you know how to manage your money.	12	0	0
Math will help you to be a better critical thinker.	11	0	1
Math is useful for helping people.	9	3	0
You should learn as much math as you can because you don't know what might be useful to you in the future.	9	2	1
You will need math for your job someday.	8	4	0
Math is important because we use it in everyday life.	8	4	0
Math is useful for making sense of the world.	6	4	2
You will need to be good at math to get into college.	3	8	1
You can use math to help make the world a better place.	2	9	1

Findings illustrated that youth (1) emphasized uses of math for money, jobs, and critical thinking; (2) conceptualized critical thinking as speed and smartness; (3) were skeptical about whether math is needed to get into college; (4) emphasized individual uses of math over relational uses; and (5) saw math's potential for helping individuals but not society at large, with

concerns about how math can be used "for bad" (e.g., making weapons). Future research should explore impacts of youth learning varied ways in which mathematics can be used to improve the world.

ROOTED IN RELEVANCE: PLACE-BASED MATHEMATICS AND RURAL STUDENTS' PERCEPTIONS OF MATHEMATICAL VALUE

Melissa Goretskie
Montana State University
megoretskie@me.com

Fenqjen Lou
Montana State University
fluo@montana.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Integrated STEM/STEAM; Modeling

Purpose

Rural students often experience school mathematics as abstract and disconnected from their lived worlds, positioning mathematics as a pathway away from community rather than a resource for participation within it (Corbett, 2011; Howley et al., 2011). Place-based mathematics education addresses this disconnect by grounding instruction in local contexts (Smith & Sobel, 2010). This study examines whether a place-based algebra modeling project using local agricultural data influences rural students' perceptions of mathematical relevance.

Theoretical Framework

Grounded in Self-Determination Theory, this study conceptualizes mathematical relevance through autonomy, relatedness, competence, and identity positioning (Ryan & Deci, 2020). Relevance was measured through four dimensions: everyday usefulness, community connection, engagement/sense-making, and future orientation (Hardré, 2011).

Method

This quantitative pre-post survey study involved 18 rural Algebra students in Montana. Participants completed a 19-item relevance survey before and after participating in a place-based modeling project. Students used CODAP to analyze local spring wheat field-treatment data.

Analysis

Mean survey scores ranged from 3.33 to 4.50, indicating generally positive perceptions of mathematical relevance. Students reported the strongest agreement on future-oriented items ($M = 4.50$) and lower agreement on conceptual relevance items ($M = 3.33$). Internal consistency reliability was high ($\alpha = .96$). Cluster analysis identified high-, moderate-, and low-relevance student profiles. ANOVA results showed significant differences across clusters, particularly for engagement and future relevance items, including Q12 ($F = 31.28$, $p < .001$) and Q15 ($F = 27.03$, $p < .001$). Post-survey responses suggested increased perceptions of community relevance and future usefulness.

Significance

This study contributes quantitative evidence on place-based mathematics education in rural secondary settings. Findings suggest contextualized modeling strengthens perceptions of mathematics as meaningful and community-connected. These findings inform equity-oriented rural mathematics pedagogy and future qualitative research.

EXPLORATORY POST-HOC ANALYSIS ON PERCEIVED NON-LEARNING FROM METACOGNITION PRACTICES AMONGST COLLEGE ALGEBRA STUDENTS

Michael N. Johnson III
University of Iowa
michael-n-johnson@uiowa.edu

Keywords: Metacognition, Undergraduate Education

College Algebra enrolls many academically vulnerable students and has high failure and withdrawal rates (Flanders, 2017; Tunstall, 2018). Metacognitive strategies can support students' planning, monitoring, and evaluation of learning (Flavell, 1979; Lovett, 2011; Tanner, 2012; Verschaffel et al., 2017).

This study examined metacognition journals from 1118 students in a redesigned College Algebra course (Farthing et al., 2026). Journal responses were inductively coded through collaborative open coding and thematic analysis (Merriam & Tisdell, 2016; Saldaña, 2016; Glesne, 2018). Analyses first compared students who reported learning something with those who did not (n = 72), then compared students who viewed the journals as productive with 475 students who rated them unhelpful, unused, or reported learning nothing. Groups were compared in R using survey measures, grades, GPA, and demographic data.

Students who learned something from the journals (LS) rated good grades and content mastery more highly than those who did not learn anything (DNLA) from the journals (5.14% higher with p = .00141); DNLA students also showed a larger decline in performance goals (8.67% with p < .00001).

By then broadening the inclusion data, students were then classified as Metacognition Journals Productive Use (MPU) or Metacognition Journals Not Productive (MNP). MNP students earned higher average GPAs than MPU students (3.08 vs. 2.74) and outperformed them on 20 of 36 academic measures (Figure 1).

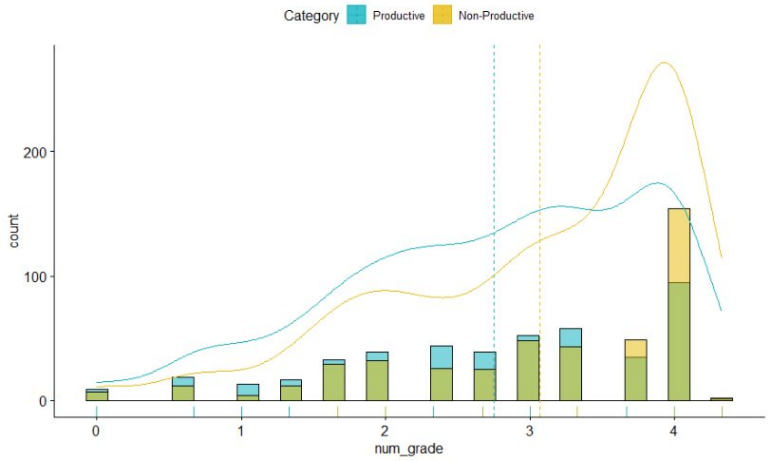

Figure 1: Distribution of Final Course GPA Between MPU and MNP

These exploratory findings suggest that stronger students may already possess effective learning strategies, reducing the journals' perceived usefulness for them. Further research should examine preparation, placement, and later mathematics outcomes.

Keywords: Mathematics Achievement, Approximate Number System, Gender Differences

Early mathematics achievement is linked to both domain-specific numerical competencies and domain-general cognitive abilities (Geary et al., 2017). Numerical cognition studies emphasize the role of early number sense and approximate number system (ANS) acuity as foundational to later math learning (Szkudlarek et al., 2017). Other studies suggest that more general cognitive abilities, such as nonverbal reasoning and cognitive control, may more strongly predict math achievement (review in Krajcsi et al., 2024). Gender differences in math have also been reported (Reilly et al., 2017). Based on the developmental framework that suggests early math performance emerges from the interaction of both core numerical systems and broader cognitive abilities (Geary, 2013), this study examines unique contributions of early general cognitive abilities (e.g., nonverbal intelligence and inhibitory control) and domain-specific numerical abilities (e.g., ANS performance) for children's math achievement, by gender.

A sample of 65 children (34 girls) aged 3–5 years participated longitudinally (predominantly White (77%), from middle-upper middle SES backgrounds). Math achievement, nonverbal intelligence, and inhibitory control abilities were measured using the TEMA-3 (Ginsburg & Baroody, 2003), PTONI (Ehrler & McGhee, 2008), and K-CPT (Conners, 2015). Then, they completed 3 computer tasks measuring their non-symbolic, symbolic, and arithmetic number sense. Hierarchical linear regression was used for analysis.

Boys (M = 106.80, SD = 15.36) demonstrated higher math achievement scores than girls (M = 101.96, SD = 11.95). Nonverbal reasoning robustly predicted math achievement across models (bs = 0.35 to 0.40, ps < .001). In contrast, the relation between domain-specific numerical abilities and math achievement varied by gender. A composite Balanced Integration Score (BIS; z-accuracy − z-response time) was associated with math achievement differently for girls and boys, such that BIS showed a stronger positive association with math achievement among girls than boys (interaction bs = –5.16 to –5.63, ps = .03 to .05). These effects remained significant after controlling for inhibitory control and age. Inhibitory control (reversely scored) was also independently associated with math achievement (bs = –3.14 to –3.37, ps = .035 to .053).

Thus, early math achievement may reflect both domain-general and domain-specific influences, but the contribution of domain-specific abilities may differ by gender before formal schooling. Understanding such pathways may inform developmental models and target support for children's early math learning. Future studies should include larger, more diverse samples and assess numerical abilities beyond the computer tasks used here.

FROM PROCEDURE TO POSSIBILITIES: TRANSFORMING SECONDARY MATHEMATICS EXPERIENCES WITH UNSOLVED PROBLEMS

nenzinger@georgefox.edu

Keywords: Identity and Agency, Problem Solving

Students often perceive mathematics as a rigid discipline focused solely on solving equations and finding numeric answers. This narrow view can discourage creativity and curiosity, leaving students disengaged and disconnected from the true discipline of mathematics (Latterell & Wilson, 2012). To combat this narrow view of mathematics, we created an elective course on exploring accessible but unsolved problems in mathematics (e.g., DeLong, 1971; Devlin, 2003; O'Dell, 2018; Freiman &Ts Abramovich, 2021) and implemented it with a group of middle and high school students. By treating students as active participants in the mathematical community rather than passive learners, we used a seminar-style approach for introducing approachable yet unresolved challenges (e.g., Halmos, 1980). Class sessions consisted of hands-on activities, collaborative discussions, and an exploration of unsolved problems. Thus, students were exposed to mathematics as a dynamic, creative, and sometimes open-ended field. The goal of this project is to see how exploring unsolved problems changes students' perceptions of mathematics.

A pre- and post-survey method captured students' views of mathematics before and after the course. We had 20 students in the class and 10 completed the pre-survey and post-survey. Participants included 7th–11th graders at a small private school in the Pacific Northwest. The course began in Fall 2025 and ended in Spring 2026. The survey consists of open-ended questions around what students' views of mathematics are and task value and critical thinking items from the Motivated Strategies for Learning Questionnaire ([MSLQ], Duncan & McKeachie, 2005). The MSLQ items were on a 1–7 Likert scale. This poster shares data on students' perceptions of mathematics, task value, and critical thinking.

The results on Task Value and Critical Thinking scores changed across the class averages. There was a small increase in students' Task Value from an average of 4.93 to 5 but Critical Thinking decreased from 4.46 to 4.12. To better understand these results, we also examined some of the open-ended questions. The pre-survey open-ended questions indicate participants primarily view mathematics as solving problems through use of formulas, numbers and calculations. Students held views of mathematics consistent with the literature of mathematics as solving problems. However, in the post-test, some students understanding of mathematics broadened, defining it as "Mathematics is working with numbers to discover new perspectives and ideas about them and using them to your advantage." Similarly, there were shifts in students answer to the question if mathematics problems always have an answer. Although only 4 of the students switched their yes or no answer portion to this question, the students that had the same yes or no, had changes in their justification. More examples and themes from students will be shared focusing on shifts in perspectives of mathematics as a closed versed open-ended field. The poster will also share ideas for revisions to the course for the next iteration of the course to help encourage more growth in task value and critical thinking.

Keywords: Integrated STEM/STEAM, Undergraduate Education

Across cultures and historical periods, humans have relied on performance (e.g., storytelling, drama, ritual, and dance) to transmit knowledge across generations. Performance has become an educational medium, shaping how complex ideas are experienced, remembered, and rendered meaningful.

Mathematics, though often positioned as abstract and symbolic, is likewise a human embodied practice (Nathan, 2021). However, with rare exceptions (Calderazzo, 2025; Kazzazi, 2020), performative dimensions of mathematical activity are rarely explored in mathematics education. At the same time, prior literature indicates that systematic integration of theatrical strategies positively affects student learning (Inoa et al., 2014). Taken together, this suggests that mathematical theater may represent a uniquely promising and underexplored site for student engagement and meaning making.

Math Connections Theater (MCT) is a sequence of original comedy sketches that span topics across the undergraduate mathematics curriculum, from pre-calculus to topology and proofs, offering a fresh embodied approach to experiencing and communicating mathematics. Housed at a large public university in the Mid-Atlantic region, the production brings together undergraduate STEM majors and members of a local sketch comedy group in sustained interdisciplinary collaboration.

The beauty of MCT is multifaceted, and its broader impact is felt by everyone involved—from the audience, who are invited to engage with mathematics in a non-traditional and humorous way, to the non-math major comedians, who are challenged to think deeply about mathematical concepts as they bring them to life on stage. By its very nature, MCT is a quintessential embodiment of mathematics—performed, acted out, and physically explored on stage.

Drawing on data from two MCT performances (October 2025 and April 2026), this poster introduces an emerging research program organized around two guiding research questions:

RQ 1: What is the nature of the MCT phenomenon?

RQ 2: What kind of impact does it have on its audience, actors, and the production team?

Data sources include surveys, semi-structured interviews with audience members and the production team, and task-based interviews with actors. Analysis is ongoing. During the poster presentation, we will share preliminary findings and discuss how STEAM initiatives like this can inform collaborations between mathematics education and the performing arts.

MAPPING AT THE MUSEUM: CHILDREN'S EXPERIENCES WITH MAP DRAWING AND VISUOSPATIAL REASONING

Maria Eloisa Nuguid
Purdue University
mnuguid@purdue.edu

Keywords: Elementary School Education, Ethnomathematics, Informal Education

There continues to be a need to support children's spatial conceptions (Clements et al., 2003). Visuospatial reasoning considers visual imagery and the dynamics of space in ways that are rooted in learners' lived experiences (Nuguid, 2026). Mathematics education literature has considered terms such as visuospatial reasoning (Goldenberg et al., 1998; Owens, 2015), visuospatial thinking (Hegarty, 2010), and visuospatial skills (Brock et al., 2018; Carlson et al., 2013). Commonalities among these three terms are spatial manipulation and visualization. This proposed study will focus on several aspects of visuospatial reasoning: (1) recognizing shapes, combinations, and their properties; (2) symmetry thinking; (3) comparing quantities and using ratios; (4) spatial capabilities; (5) locating; (6) intention and attention; and (7) space and place (Owens, 2020). Mathematics education scholars have used mapping tasks to study visuospatial reasoning (Nuguid et al., 2024; Richardson et al, 2024; Suazo-Flores et al., 2023). Mapping is a visuospatial task that will be the focus of this study. I argue that children's experience with mapping contextualizes their lived experience in a reframed structure that has mathematical elements.

The objective of this study is to investigate children's experiences during a series of mapping tasks, where the research question is: "How do children experience mapping?" Children will be tasked with drawing a series of maps using the following prompts: (1) Draw a map from home to school (Cohrssen & Pearn, 2021), (2) draw a map of your choice, and (3) draw a map of three of your favorite places at a children's museum (e.g., dinosaur dig site). A case study methodology (Merriam & Tisdell, 2015) will be used to investigate the cases of four to six children's experiences with mapping. The Mosaic Approach will guide data generation by positioning children as experts in sharing their experiences (Clark & Moss, 2017). Participants and I will use Owens' (2020) framework to identify aspects of visuospatial reasoning via procedural analysis (Saldaña, 2021). For example, I will ask participants to place Post-it® notes to identify shapes in their map, aligning with Owens' (2020) first aspect of visuospatial reasoning about recognizing shapes and their combinations. Cultural-historical activity theory (CHAT) (Engeström, 2000; Yamagata-Lynch, 2007) will serve as the primary analytical framework for examining how children's mapping experiences are mediated by several components that form mediation triangles (e.g., subject, object, tool, rules, community, division of labor, and outcome). Theories of experience will inform the interpretation of children's storytelling about their maps (Bruner, 1986; Dewey, 1938; Glasersfeld & Ackermann, 2011). For example, Bruner (1986) suggests that storytelling is one way that experiences become a reality. This proposed study aims to celebrate the various ways in which children know and do mathematics through mapping, echoing ethnomathematics (D'Ambrosio, 1985).

Acknowledgments

BUILDING CLASSROOM CONNECTEDNESS THROUGH DISCOURSE

Jessica Pierson Bishop
Texas State University
jbishop01@txstate.edu

This paper explores an interpersonal and relational aspect of mathematics classrooms—what I describe as classroom connectedness—using social network analysis. Classroom connectedness is the extent to which a classroom collectively values, encourages, and cares for individuals within the group. In connected classrooms, group members make contributions to shared goals, purposes, and activities while also depending on one another to achieve those goals (Goodenow, 1993; Strayhorn, 2019). Using networks, I map whole-class mathematics discourse in one middle-grades classroom as a case study to investigate how classroom connectedness is built through dialogue. Results show that certain types of interaction including caring interactions and diverse perspectives help build connectedness; that students play important roles developing connectedness; and that non-mathematical talk helps support mathematical talk.

Keywords: Classroom Discourse, Identity and Agency, Instructional Activities and Practices

> [This year I have learned] to try new things. Not just to think that one way would work all the time. Not to give up so easily. … When we share and other people show their strategies, I noticed that different ways would work. Everyone's not judging everybody else, and they accept the ways you're thinking. And help you think about other things. … Like I said before, I used to give up a lot. I was insecure I wouldn't get it right. And I have to admit I was a crybaby. I got frustrated a lot. (Aujane, Grade 5)
>
> A successful math student in our class listens to everyone. If you hear someone say something that might not make sense or might be wrong, like you don't understand how they got it, you would ask, "What do you mean by that?" And then sometimes you end up correcting them. But sometimes you realize that you were wrong. … You help other people, but you also allow yourself to be helped by other people. (Erin, Grade 5)

Erin and Aujane were students in the same fifth-grade classroom. What was it about their classroom that enabled them to feel this way? What supported this change in Aujane where she used to cry and give up but now sees herself as capable and persistent? In this paper, I focus on a feature of mathematics classroom discourse—classroom connectedness—that I believe is instrumental to productive, mathematics interaction but which may be, at times, peripheral to the mathematics under consideration. As an example, consider the following excerpt from Erin and Aujane's classroom.

> Teacher: This morning I want you to think about your 100% smarts. Turn and look at your plate right now. [On the wall are paper plates students partitioned into different smarts based on their relative strengths or smarts.] They all look different. Why?
> Macy: They all look different because we all have different sorts of smarts. Like we could be all big in Body smarts, but we're not all the same percentage big. …
> Bella: They're all different because we're all different. So if we mix them all up we can like, people can help each other. Like if I was struggling with math and Macy had like really high math smarts, I could ask her for some help. And she could build up mine a little bit more. …

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Paris: If we're all the same, then nobody can help us with our struggles.
Aujane: I wanted to add to Bella's because I think she was like saying that if you have a smart and then you help somebody to make your smart grow with their smart. Then they help you in their biggest strength and you grow in their biggest strength if that wasn't your biggest one.
Teacher: Right. We've got a few more people who would like to add on.

In previous work, I have focused more on the mathematical aspects of classroom discourse and, as a result, excluded these kinds of interactions from analysis because they did not clearly address mathematics content. But I began to wonder if part of the reason why Erin and Aujane's classroom was able to have productive mathematics conversations was precisely because they also had conversations about their "100% smarts." In this study, I explore an interpersonal and relational aspect of mathematics classrooms—what I call classroom connectedness—using social network analysis. Classroom connectedness is the extent to which a classroom collectively values, encourages, and cares for individuals within the group. In connected classrooms, group members make contributions to shared goals, purposes, and activities while also depending on one another to achieve those goals (Goodenow, 1993; Strayhorn, 2019). To understand how mathematics classroom connectedness is built through dialogue, I mapped whole-class mathematics conversations using networks to visualize who contributes and in what ways.

Theoretical Perspectives & Related Research

Psychologists argue that connection, or belonging, is a core human need (Maslow, 1943; Ryan & Deci, 2017), and sociolinguists like Halliday (1978) claim that personhood is predicated on membership in a social group, with language being the primary means through which this process occurs. Whether using the term caring (Hackenberg, 2010; Noddings, 1984), sense of belonging (Goodenow, 1993; Strayhorn, 2019), community (Boyer, 1990), or connectedness (Maloney & Matthews, 2020), scholars across disciplines and using various methods of inquiry recognize the importance of forming strong connections to peers and social groups. In fact, Noddings (1984) argues that we are irrevocably linked to others and "this fundamental relatedness is at the very heart of our being" (p. 47). Moreover, research has shown that sense of belonging or connectedness is positively related to other desirable outcomes like retention and persistence in course taking (Good, 2012; Strayhorn, 2019); motivation and engagement (Goodenow, 1993; Middleton et al., 2017; Strayhorn, 2019); and academic achievement (Battey et al., 2016; Good et al., 2012; Noddings, 1984; Strayhorn, 2019; Wilson, 2022).

Across the literature, some frame connectedness as an individual trait of students measured through Likert-scale surveys (Good et al., 2012; Maloney & Matthews, 2020; Strayhorn, 2019), whereas others frame connectedness as a dyadic relationship between two people—typically a teacher and student (Hackenberg, 2010; Noddings, 1984), and still others frame connectedness as a component of teachers' instructional practice or particular teaching moves (e.g., Battey et al., 2016; Matthews, 2020; Wilson, 2022). The relational features and instructional practices focus primarily on *teachers* and how they support classroom connectedness. I wish to extend this work by incorporating what *students* say, do, and contribute to classroom connectedness. Thus, I conceptualize classroom connectedness as a social and malleable, group-level construct comprised of moment-by-moment interactions, aggregated over time and individuals, and operationalized using networks. Discursive interactions, accumulated across classroom members and over time, constitute the larger community to which students belong. However, some discursive exchanges are more important than others in creating classroom connectedness

because they have the opportunity to communicate to students that others care for them, want them to be successful, value their thinking, and will act to help further their learning goals (Noddings, 1984). Table 1 synthesizes the extant literature into five components of mathematics classroom connectedness that research suggests are important to building and promoting connectedness: contributing and being included, caring and feeling valued, emotional support, explicit norms and expectations, and diversity of perspectives. I use the components in Table 1 as both a conceptual and analytic tool for the research presented here. The research questions I sought to answer are: (1) How is classroom connectedness built through mathematics discourse? and (2) How can social network analysis be applied to mathematics classroom discourse to model mathematical and social relationships to measure classroom connectedness?

Table 1: Components of Mathematics Classroom Connectedness

Component	Description	Supporting Literature
Contributing and Being Included	To what extent are classroom members noticed, included, and contributing to the social group/classroom?	Strayhorn, 2019; Noddings, 1984; Goodenow, 1993; Wilson, 2022; Wilson et al, 2019
Caring and Feeling Valued	To what extent are classroom members cared for and valued? To what extent do community members seek to understand one another's ideas and support each other's (learning) goals?	Goodenow, 1993; Hackenberg, 2010; Noddings, 1984; Matthews, 2020; Strayhorn, 2019
Emotional Support	To what extent are classroom members' emotions and affect recognized, affirmed, and supported in classroom dialogue? To what extent is one known outside of math?	Hackenberg, 2010; Jaber & Hammer, 2016; Maloney & Matthews, 2020; Noddings, 1984; Rolon-Dow, 2005; Wilson, 2022; Wilson et al, 2019
Explicit Classroom Norms and Expectations	To what extent does the classroom explicitly state normative values, beliefs, and expectations?	Battey et al., 2016; Cobb et al., 2009; Kazemi & Stipek, 2001; Jaber & Hammer, 2016; Ware, 2006; Wilson, 2022; Wilson et al., 2019
Diversity of Perspectives	To what extent are multiple, different ideas and perspectives encouraged?	Strayhorn 2008, 2019

Methods

Participants and Data

To answer the research questions, I used a case study approach, investigating one fifth-grade classroom across a single academic year. I purposefully selected the case to maximize the likelihood I collected data in a classroom with high levels of classroom connectedness. Thus, I selected an experienced teacher widely recognized by her colleagues, administrators, and other researchers as an excellent teacher (across all subject areas including mathematics). Teacher K had over 30 years of teaching experience, participated in many research studies (including the original Cognitively Guided Instruction study), and routinely facilitated mathematics professional development. Teacher K's class was a self-contained, inclusion classroom in a diverse school located in the northern US (40% economically disadvantaged, 26% English

learners, 38% White, 10% Hispanic, 20% Black). The participants were Teacher K and her 20 fifth-grade students. Data was comprised of video recordings and transcripts of three algebra and nine fractions lessons, totaling 17 hours of instruction across the academic year. I chose the topics of algebra and fractions because of their significance in secondary curricula and overall academic success. Four lessons were filmed in early November, four in mid-March, and the final four in May. As secondary data sources, I conducted interviews with Teacher K and a subset of students to explore what math class was like from their perspective.

Methodological Approach: Operationalizing Connectedness With Networks

I used networks, or graphs, to document and visualize who participated in whole-class mathematics instruction and in what ways. Social network analysis considers both group and individual characteristics when explaining activity or behavior but its underlying assumption is that it is the relationships that have a profound influence on social life (Borgatti et al., 2018; Carolan, 2014). Thus, its emphasis is on social ties and emergent, coordinated activity reflected in network structure and patterns. To represent classroom discourse as a network, a vertex was assigned to every classroom member (including the teacher). I created a Class vertex for instances when the class was addressed collectively and a Student node for unattributable student utterances. For each whole-class turn of talk, an edge and its directionality were assigned on the basis of who (source vertex) addressed whom (target vertex). Additionally, I also created edges when a speaker explicitly addressed a classmate's idea or contribution in their turn of talk, but was not talking to that classmate. (See Example 2 in Table 2 below.) I included these situations to capture instances in which students have made mathematical contributions that extend beyond the specific utterance. Their idea adds to the collective understanding as others refer back to that idea. These situations reflect that someone has made a significant contribution to the mathematical goals of the classroom. By incorporating the previous ideas referenced as an edge, this coding decision helps measure whose ideas are taken up and which students may play important connective roles in linking, clarifying, or challenging their peers' ideas, which are critical components of connectedness. Because I was unable to collect data from all small groups during data collection, I could not represent all of the discourse during a given lesson using networks. Thus, the networks shared in this paper are restricted to whole-class interaction during dedicated mathematics instruction time, but include both mathematical and non-mathematical turns of talk (i.e., social, behavioral, managerial) that occurred during the math lesson.

Table 2: Operationalizing Edges as the Unit of Analysis

Ex	Turn of Talk	Source	Target	Rationale for Edge
1	*Aarya*: Actually, our strategies are the same Erin. We just wrote it down different.	Aarya	Erin	Aarya addresses Erin
2	*Teacher*: Aujane, what do you think she [Bella] is missing?	Teacher	Aujane	Teacher addresses Aujane
		Teacher	Bella	Bella's expression is focus of teacher request

For each turn, a directed edge is identified by linking a source node to its corresponding target node(s). The creation/inclusion of an edge is one way I am capturing the extent to which classroom members are noticed, included in, and contributing to the classroom dialogue. I used this analytic process to create networks for each lesson. Figure 1 (see "Results") is a network

created from one 93-minute lesson in Classroom K (the second of 12 total lessons). In this lesson there were 295 edges across 20 vertices in 46 minutes of whole-class math instruction. Note that multiple edges between a pair of vertices indicates multiple, distinct directed turns of talk between two classroom members during the lesson. The size of the vertex was scaled to reflect its degree, or the total number of incoming and outgoing edges. The vertices' degrees capture members' involvement in the lesson; thus, the larger the vertex, the more that person has contributed to the lesson. However, as described in the literature review, I identified specific features of interaction related to connectedness. Because some turns of talk appeared to be more critical to creating classroom connectedness, I further classified each edge based on the nature of the utterance. For each edge, I determined if the turn of talk could be categorized into one of the connectedness components listed in Table 3. These categories are not mutually exclusive; meaning that a single turn of talk can address more than one connectedness component.

Table 3: Analytic Framework for Mathematics Classroom Connectedness

Component & Operationalization	Examples
Contributing: One is included when they make a contribution, have a contribution directed to them, and/or their ideas contribute to the math goals of the class.	This component is captured with the creation of an edge.
Caring: Identify utterances in which (a) one seeks to understand another (Noddings's [1984] engrossment) or there is evidence one does/has understood another (e.g., revoice), and (b) support another's goal (Noddings's [1984] motivational displacement)	*Grace*: I knew that there was ten pies, so I wrote a little ten here to remind myself. And then so I kind of thought of it like Charles but I just didn't draw my picture, because I had it in my head. I just drew an equation but Charles had the picture. … [evidence one has understood another]
	Teacher K: Can I put Charles's work up here [on doc camera] so you can say this is the parts, this is the ten pies? [supporting another's (Grace) goal]
Emotional Support: Statements acknowledging, recognizing, and affirming community members' emotions and lives outside of math including: Verbal/nonverbal praise or affirmations; statements of support; statements of uncertainty; Sharing out-of-school experiences, hobbies, interests, or family.	*Teacher K*: I realized last night that you guys are like, why is Ms. K even thinking about weight measures? Because most of the recipes we use are in cup measures. … This is my grandmother's cookbook from 1913. And this is the problem. Look at my recipe. How much flour does it use? Three-fourths pound. But I cook in cups. How would I ever know what ¾ pounds is? Do you notice that I have to do some mathematics? So I thought I would give you the reason why. Maybe it builds a little context for you.
Explicit Norms & Expectations: Explicit statements reflecting beliefs about math, math ability/success, expectations for engagement and behavior, and	*Teacher K*: I want you to think about what math is to you. What is math and what is it comprised of and how can you be stronger in one area of math than another area of math? Think about things that are easy for you, challenging for you, or frustrating. … And I wonder, do you think it's true we'll find out that everyone is math smart?

acknowledging emotions and feelings with respect to math.	
Diversity of Perspectives: The extent to which multiple, different ideas/perspectives are encouraged and observed as indicated by disagreements, requests for an alternative idea or strategy, and meta-level comments about multiple solutions or differences.	*Morgan*: But we're all unique and our families are all unique and that's what makes us who we are and are special. [meta-level comment]
	Teacher K: Anybody else have a way that's different than, than Drew's?

Results

To visualize connectedness, I created networks to document who participated in whole-class math interaction. The network in Figure 1 (and all networks in subsequent figures) is a representation of one lesson in Classroom K. The network shows that the teacher receives and directs more talk than anyone else (as seen in the relative size of the vertices which are scaled based on degree). However, some students make significant contributions to the class (Charles, Bella, Aujane, Elias and Elijah). Visual features of the network in Figure 1 such the number of isolated vertices (there is one, AJ), the number of student-student edges, and the size of student vertices suggest Classroom K is a connected classroom. Network measures such as density—the proportion of existing edges out of the maximum number of possible edges—confirm this. (Network density for the graph in Figure 1 is .776, meaning 78% of all possible edges in a complete graph exist. Density accounts for the presence of an edge between pairs of vertices, not the number of edges between pairs.) Visualizing mathematics classroom discourse using graphs reveals features of connectedness that might not otherwise be noticed (e.g., isolated vertices, timing of student contributions in the lesson) and provides new ways of visualizing which community members contribute (or not), how much they contribute, the extent to which their contributions are taken up, and who directs the conversation.

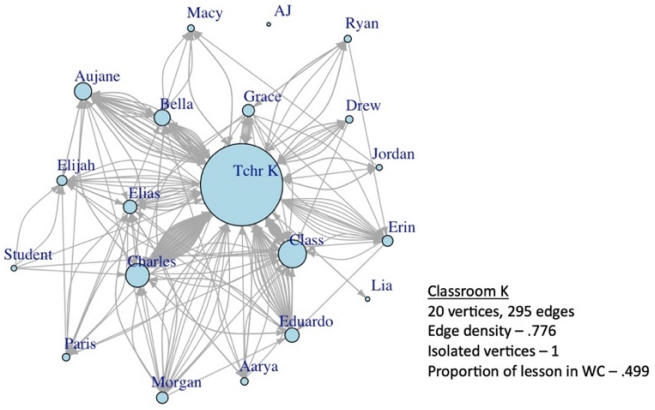

Figure 1: Network For All Turns of Talk in Classroom K

Although participating in the classroom and making discursive contributions is a necessary aspect of classroom connectedness, it seems that certain types of interaction, like Caring interactions for example, may be particularly important for creating community. Caring

interactions focus on mathematics but do so in a way that communicates to students their class values them, is invested in their success, and will act to help further their learning. Moreover, caring interactions are one way connectedness is built over time. Consider the graph of Classroom K in Figure 2 which reflects only edges coded as a Caring interaction. In this graph, multiple directed edges are combined into a single edge whose thickness reflects the number of directed turns between a given pair, and the size of the vertex reflects the total degree. Perhaps one of the more striking features of this graph is the number of Caring interactions (90 out of 295 total edges, or 31%, are caring interactions) and the large amount of student-student caring.

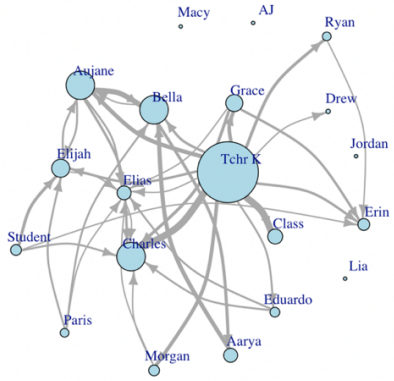

Figure 2: Network for Caring Turns of Talk in Classroom K

Further, consider who receives and who initiates Caring interactions which is shown in the networks in Figure 3. The vertex size for the graph on the left reflects in-degree (the number of caring comments directed toward, or received, by a community member) and the vertex size for the graph on the right reflects out-degree (the number of caring comments a member directs to another). Students whose vertices are relatively large in the left graph (Charles, Bella, Aujane, Elijah, Erin, Elias) may feel particularly valued and cared for, whereas students with larger vertices in the right graph (Aujane, Grace, Aarya, Paris) may play an especially important role in helping others feel cared for. In fact, student initiations of caring interactions, as reflected in the right graph, are an important indicator of classroom connectedness because they reflect the adoption of shared values, expectations, and norms. These students believe they learn better together which is seen in Erin and Aujane's quotes at the beginning of the paper.

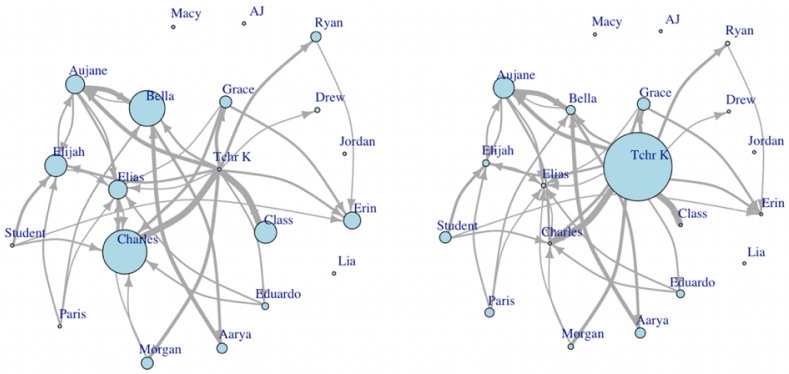

Figure 3: Classroom K Caring Networks: Vertex Scaled by In-Degree and Out-Degree

Another result from this analysis is that non-mathematical talk helps support the quality of the mathematical talk. In Figure 4, edge color is used to represent the different components of connected classrooms in the analytic framework. Though many of these interactions are not explicitly mathematical (e.g., purple edges for emotional support or orange edges for making norms explicit), this kind of interaction seems to provide the foundation upon which students feel comfortable taking intellectual risks, sharing their ideas and mistakes, monitoring their own epistemic affect (Jaber & Hammer, 2016), and responding to peers' ideas. And finally, a defining feature of each network shared is the prevalence of student-student edges. Classroom connectedness was not the sole responsibility of the teacher; students actively initiated Caring interactions (38 of 90 total instances of caring were student initiated), provided emotional support (6 of 9 total instances of emotional support were student generated), and encouraged diverse perspectives (18 of 22 instances were student initiated). Thus, students play an important role in mathematics classroom connectedness.

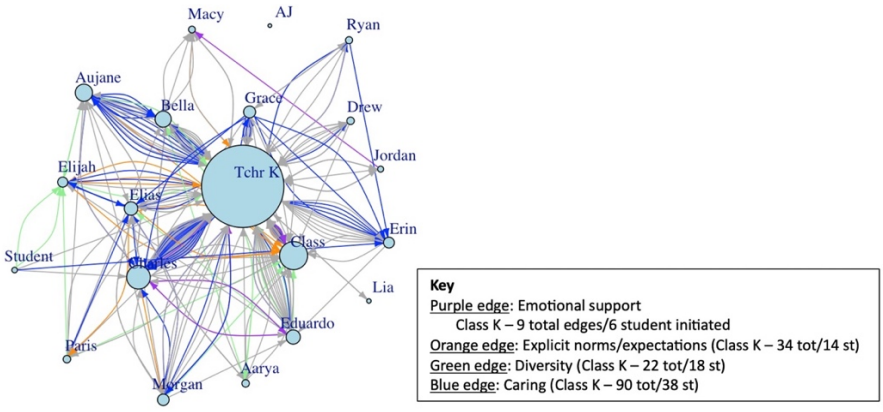

Figure 4: Classroom K Network: All Turns of Talk and Connectedness Components

Conclusion & Discussion

This study contributes to the field by providing a new methodological approach to investigate classroom connectedness and conceptualizing connectedness as a malleable, social construct emerging through moment-to-moment classroom discourse. Using networks and the components described in our conceptual and analytic frameworks, I mapped whole-class mathematics discourse in one middle-grades classroom to investigate how classroom connectedness is built through dialogue. Results of our network analyses show: (1) networks are a promising methodological tool to represent social and academic relationships; (2) certain types of interaction including the presence and prevalence of turns of talk reflecting caring interactions are particularly important to building connectedness; (3) students play critical roles in developing connectedness by taking responsibility for their own and others' learning when they initiate interaction with peers; and (4) non-mathematical talk helps support mathematical talk. In this study, I found that although some components of classroom connectedness may not focus on content, they provide the foundation on which students feel comfortable taking risks, sharing ideas, and responding to their peers' ideas. If, in Nell Noddings words, "the student is infinitely more important than the subject matter," then perhaps spending time to create a connected classroom rather than covering one more section is time well spent (1984, p. 176).

EXAMINING SYMBOLOGY IN INTRODUCTORY STATISTICS THROUGH A UNIVERSAL DESIGN FOR LEARNING (UDL) LENS

Laura Kyser Callis
Curry College
laura.callis@curry.edu

Jennifer Ceven McNally
Curry College
jmcnally@curry.edu

Mathematical symbology can pose barriers in increasingly diverse introductory statistics classrooms. This qualitative study examines instructional practices that support students' developing symbol sense through a Universal Design for Learning (UDL) lens, focusing on UDL Considerations 2.1 and 2.2. Data include interviews with 39 students, surveys from 86 students, and video-stimulated recall interviews with five instructors. Findings indicate that students view symbols as essential yet initially intimidating, and that symbol sense develops through intentional instructional mediation. Effective practices included explicit attention to symbol morphology, translation between symbols and natural language, structured reference tools, revisiting symbols, and highlighting relationships among symbols. These strategies appeared to support students' developing sense of symbols and promoted more equitable access to statistical meaning-making.

Keywords: Communication, Instructional Activities and Practices, Undergraduate Education

In recent decades, there has been increased attention to conditions that support students' access to postsecondary Science, Technology, Engineering, and Mathematics (STEM) courses and programs. As the world becomes increasingly shaped by data, quantitative reasoning and statistical literacy have been a keen area of focus for postsecondary educators and researchers. Effectively communicating data findings clearly, concisely, and efficiently requires the use of symbols e.g., (Bardini & Pierce, 2015). However, research on instructional strategies that develop students' symbol sense is nascent (e.g., Begg & Pierce, 2020; Esuong et al., 2022; Mutodi & Mosimege, 2021; Oyoo, 2022).

Today's postsecondary instructor is confronted with increasing diversity in the mathematical experiences that their students have had in secondary schools (Han et al., 2023), with at least eight distinct course-taking typologies. Whereas there had traditionally been a standard pathway of algebra I, geometry, algebra II, advanced mathematics, now only 14% of students complete that sequence, calling into question whether there is a shared foundational understanding amongst incoming postsecondary mathematics students. Additionally, students with diagnosed learning disabilities continue to grow as a segment of the overall higher education student population (National Center for Education Statistics, 2019), suggesting that the postsecondary mathematics classroom is rich in diversity.

Universal Design for Learning (UDL) is an empirically-supported framework for designing instruction to reduce barriers and increase success for all learners with a focus on those who have historically been excluded from learning opportunities (CAST, 2024). Rooted in design principles, UDL empowers educators to identify and mitigate barriers to students' learning that exist in the educational environment. UDL outlines general recommendations for multiple means of student *engagement*, content *representation*, and *action and expression*. Descriptive guidelines for content representation include several that address symbology: 2.1 Clarify vocabulary, symbols, and language structures; and 2.2 Support decoding of text, mathematical notation, and symbols. Providing specific and detailed descriptions of context-specific applications of UDL may help instructors enact the design principles of this framework in their

own practices. In this qualitative study, interviews with students and instructors lend insight into the instructional practices in introductory statistics classes that support students' developing symbol sense. This study asks: What instructional practices do introductory statistics instructors employ to support students' developing symbol sense, and how do students experience those practices?

Literature Review

Mathematical symbols are central to precise and efficient communication of concepts, relationships, and ideas in quantitative disciplines (e.g., mathematics, statistics, physics, natural sciences). Yet, for many students, the price of this conciseness is that ideas are presented abstractly, which presents challenges in the teaching and learning environment. Instructors are reminded that "it is too easy to assume that our students are thinking what we are thinking as we use and read symbolic expressions" (Begg & Pierce, 2020, p. 7). Explicit attention to symbology in the mathematics and statistics classroom is needed to ensure shared understanding and to build students' symbol sense as they become more confident communicators of quantitative ideas.

Universal Design for Learning calls instructors' attention to differences that may exist in students' ability to access information as it is presented with specialized vocabulary and symbols. Consideration 2.1 reminds instructors that "the semantic elements through which information is presented—the words, symbols, numbers, icons, and language structures—are differentially accessible to learners with varying backgrounds, languages, and lexical knowledge." Instructors must confront any taken-for-granted assumptions that students share the same understanding gleaned from symbols as they do.

Much of the existing research on mathematics symbology is grounded in the secondary school context. These findings highlight the density of symbols in the fields of mathematics and statistics while presenting several instructional suggestions. There is a need for instructors to recognize the volume of symbols that students encounter (e.g., Oyoo, 2022), that they exist with different alphabets, cases, and fonts (Begg & Pierce, 2020), and that some are polysemantic or are homonyms (Mutodi & Mosimege, 2021). Students' prior experience with individual symbols interacts with how they make sense of them in novel situations (Chin, 2013). Students' prior experience with individual symbols may be productive when a new meaning or context extends what is already understood; unproductive, such as when a symbol homonym appears in a new context with a distinct meaning; or nonexistent, as in the case when students are exposed to a symbol for the first time. The use of symbols increases students' cognitive load, especially as they are becoming more fluent with them but over time can help students accommodate the cognitive demands of mathematical thought (Mutodi & Mosimege, 2021; Oyoo, 2022; Sfard, 2008). Students' affective responses to symbols (including anxiety, frustration, and intimidation) represent an additional dimension of this challenge. Prior research on mathematics anxiety suggests that negative emotional reactions to symbolic notation can compound cognitive difficulties, particularly for students who have had limited prior exposure to formal mathematical symbols (Ashcraft & Krause, 2007).

There seems to be consensus in the research literature that teacher mediation of symbols is necessary for students to develop their symbol sense. Arcavi (1994) coined the notion of symbol sense to describe the intuitive and flexible feel for symbols and symbolic forms, including an understanding of when and how to use them meaningfully. Esuong and colleagues (2022) advocate for word-to-word translation and interpretation, finding that a specific mathematics symbol instruction treatment promoted students' algebraic word problem solving ability. Other researchers agree that alerting students to symbols and their meaning supported

students' symbol sense development (e.g., Mutodi & Mosimege, 2021; Oyoo, 2022). As Sfard (2008) describes, there is a "process of proper naming (baptizing)" (p. 169).

Calls for increased attention to symbol instruction exist throughout the research literature. While Mutodi and Mosimege (2021) lament that "teachers do not reflect and devise teaching approaches that promote conceptual understanding and representational efficiencies," it is not clear that this is a general truth (p. 1195). Examining instructional practices that students and instructors identify will help to contextualize the ways that symbol sense development engages students in "action [...] on their part to develop a deep level of mathematical understanding" (Mutodi & Mosimege, 2021, p. 1185).

Methodology

This inquiry is one component of a larger project that is supported by a National Science Foundation Improving Undergraduate STEM Education grant (NSF IUSE #2314358). Quantitative analyses identified five instructors of introductory statistics at Curry College whose students have demonstrated improvements in pre-/post-test scores on statistical concepts (Callis et al., 2026). All five instructors also reported familiarity with UDL and had participated in professional development related to inclusive instructional design, making them well positioned to reflect on how their practices addressed learner variability. Students (n = 39) of these five instructors participated in semi-structured interviews to share their perceptions of the instructional practices that their instructors used, and an instructional practices survey was administered to 165 students and returned by 86. Additionally, these five instructors participated in video-stimulated recall interviews (n = 8) in which a video-recorded classroom session of the interviewee was viewed alongside a member of the research team, with questions posed about instructional decisions evidenced in the classroom episode and interviewees' rationale behind them. Clips for the video-stimulated recall interviews were selected by the research team prior to each interview to highlight episodes representing a range of instructional decisions, including moments where students appeared to struggle with or engage symbology. Interview questions invited instructors to describe their reasoning (e.g., "What were you thinking when you introduced that notation?" and "What were you hoping students would take away from this?"). Ethical review and clearance processes for research involving human subjects (instructors and students) were conducted by the Curry College Institutional Review Board. All names in this article are pseudonyms.

The interview transcripts and open-ended survey responses were read and reread by several members of the research team and deductively coded to identify alignment to specific UDL considerations. Axial coding followed, in which the utterances clustered by UDL considerations were explored for patterns, connections, and relationships (Corbin & Strauss, 2015). Initial codes were derived from the UDL Guidelines themselves (e.g., "clarifying vocabulary," "supporting decoding of notation"), and were applied independently by two members of the research team before being reconciled through discussion. As analysis progressed, codes were refined to capture more nuanced instructional moves (e.g., "morphology attention," "symbol translation," "structural relationships"), and memos were written to document analytic decisions and emerging interpretations.

Results

Analyzing the data revealed insight into the value students and instructors attach to symbols in the introductory statistics classroom, and what instructional practices seem to be supportive of students' developing symbol sense. These themes are detailed below.

What Value Do Students and Instructors Assign to Symbols?

Students appear to recognize the importance of symbology to communicate ideas in the introductory statistics class. They spoke of statistics vocabulary and symbols as "important" and requiring effort to learn. Students characterized the symbols as "fancy," "weird," and "different from regular math," which indicates that they may have limited prior experience with the symbols and the way they were used.

As alluded to in the research base, the context and syntax in which symbols were used interacted with the meaning and appropriate use of specific symbols. Students seemed to notice this, recognizing that their efforts to understand the meaning of symbols could be stymied by underappreciating the context. As Avery shared, "the way the professor explains them might be different from the way, if you Google it, it's explained … I learned that the hard way. But once I realized that was important, I was like, 'OK, I need to actually go to class.' and then it was fine." Students seem to be aware that symbols can carry multiple meanings, and that making sense of them depends on context.

While students seem to appreciate the value of symbols as tools to communicate ideas, they are daunted by them. A survey respondent shared, "sometimes I get lost in the symbols and long equations," and several interviewees expressed their discomfort with encountering symbols in their classwork and homework. When asked to give advice to future statistics students, Madison said, "Don't be scared by equations. Like, try to break everything down and definitely go to tutoring." Ryan, a student in a different class, seemed to agree when he said, "It's intimidating. You need to look at it and not get overwhelmed by the equations because there's Greek letters, there's symbols, but it's doable." Students seemed to have an initial fearful reaction to symbology that they felt they could overcome. As Ryan added, "it's like a puzzle. You have to start it and then once you get it done, it's not that difficult." Students find symbols to be challenging but important, and demystifying them is achievable.

Instructors have a similar regard for the importance of symbols. As Dr. Landry shared, "I think I really understand why we as mathematicians use symbols. I feel like I am saying a lot of words and I'm catching myself not being perfectly precise … and you can see patterns with symbols that you can't see with words." She values the use of symbols to communicate a thought precisely and efficiently, but recognizes that students are still in the process of learning all that symbols encode. She wistfully remarks, "maybe over time I'll just be able to write that on the board and they'll understand it!" All of the instructors referred to how they attended to symbology in the lesson that was the subject of the video-stimulated recall interview.

Developing students' symbol sense was something these instructors viewed as an ongoing process. Mr. Jackson commented about how he makes symbols and their meaning explicit "regularly" and that "it works to do a lot of reinforcement." Dr. Landry explained that she "feels like we have to spiral the vocabulary and the symbols," revisiting symbols and their meanings again and again over the course of the semester. These instructors seemed to view symbology as an instructional focus that requires ongoing attention.

Instructional Strategies to Support Students' Development of Symbol Sense

Developing students' symbol sense was something instructors and students recognized required conscious attention. For Dr. Scott, symbology was one of the two instructional objectives for the class that was observed for the video-stimulated recall interview. He explained that in a previous class, students had not "used symbology or critically talked about" the structure of hypotheses for a test of a single mean, and that it was a focus for that class session. For Ms. Thompson's class, translating statistics concepts into statements using symbols

was likewise an instructional focus, with students building from statements written in words and translating them into concise symbolic expressions of hypotheses.

The conscious attention that symbol instruction required was multi-dimensional. Symbols were introduced by attending to their morphology and meaning. Dr. Landry's classroom episode included a demonstration where she wrote the symbol μ (mu) on the board and explained that it may look different from how μ (mu) is presented in the textbook. In her interview, she explained that one of her students told her he did not recognize that what she wrote on the board was the symbol μ (mu), "Even when I write it carefully, he said it looks like an M." It made her reflect on an article she had read about a student with dyslexia experiencing mathematics and building a personal lexicon for symbols (Lewis & Lynn, 2018), and she concluded, "You keep making it explicit. Every single lesson."

While morphology is important for students to recognize symbols in the various styles they can be written, conscious effort is also needed for students to glean meaning from those symbols. Dr. Scott's student Madison appreciated his word-for-word translation symbols:

> He has a notes app that he screenshares to the board. I like being able to see him write out equations and explain them and write them in plain English so I can understand it. It has been really helpful because at times I won't understand the fancy stats words and seeing it in plain English has really helped me process it. Like, "OK, that's what I need to think."

Later in the interview, Madison shared her process for translating a novel equation into plain English using Google image search and Photomath, mimicking the word-by-word process that she experienced in Dr. Scott's class.

Students appreciated collecting symbols and their meanings on a reference list. In some classes this was a poster displayed on the wall of the classroom and in others students kept personal glossaries of key vocabulary words and symbols. Avery appreciated having a dedicated place to record this information, "instead of me scrambling through my notes." Her instructor, Dr. Young, used a Frayer model graphic organizer for students to record the symbol, its meaning, examples, and nonexamples (Frayer et al., 1969).

An interesting episode in Dr. Landry's video-recorded lesson involved her developing a matrix to notice patterns and features about the structure of how symbols are assigned to ideas in statistics. She drew a 2-by-2 table on the whiteboard to demonstrate that population parameters are encoded with Greek letters while sample statistics use Roman letters with an accent. The symbol for the mean of quantitative data uses a variation of the letter "m" while the symbol for proportions for categorical data use variations of the letter "p." In the video-stimulated recall interview, Dr. Landry explained her rationale for attending to the structure of symbols:

> You want them to see similarities, right? And parallel constructs. So, I was trying to show them, look, these things have this in common. And they are about the same kind of variable. And we're just moving to new kind of variable that we're talking about the same kinds of ideas. Like, we know experts have organized knowledge, right? I don't want them to feel like they have to memorize a bunch of different symbols, which they do. But if they can like reason through them, then maybe they can become more fluent.

For Dr. Landry, the meaning encoded in symbols was structured and revealed patterns that students may otherwise overlook. Her directed attention to the organization of symbols was intended to support students in becoming more fluent in their thinking about statistics concepts in addition to symbols.

Instructors seem to value and encourage students to express ideas in informal language before formalizing ideas symbolically. Dr. Young spoke of the importance of having students "articulate what's happening in spoken word" and Ms. Thompson recognized that "there's a lot of technical language and complex ideas." For Dr. Scott, having students use informal language allows him an "opportunity to reassess" whether students are making sense of key concepts before attempting to encode them symbolically. It seems important for Mr. Jackson to know whether students can distinguish ideas and then apply the correct symbology to those ideas – he explained in his interview that he consistently asks students questions like, "Is it the population mean or the sample mean? And what's the symbol for sample mean?" so that students can more confidently express their ideas symbolically.

Discussion

While Mutodi and Mosimege (2021) contend that instructors are not strategic in engaging students in developing symbol sense, the instructors in this sample offered multiple examples of doing so. These instructors, who are familiar with Universal Design for Learning and attuned to challenges their students may face in the learning environment, exhibited specific strategies and approaches to attending to symbol sense development. It appears their orientation to recognizing the diversity of students' cognitive profiles helped them to empathize with their students and identify ways that symbolic expression could be a barrier to understanding and communicating in the statistics classroom.

That all instructors referred to instances in the video-recorded classroom episode where attention was paid to symbol sense indicates that they believe, as Begg and Pierce (2020) contend, "the complexities of notation and the use of symbols is a reality that cannot be avoided." Rather, they seek ways to enact UDL principles, such as ensuring that learners have "consistent and meaningful exposure to symbols to comprehend and use them effectively" (CAST, 2024). Students and instructors alike regard symbols as important tools for efficient communication. Including symbology as an instructional objective or a focus of instruction ensures accessibility for all students, recognizing that learners have "varying backgrounds, languages, and lexical knowledge" (CAST, 2024). In this study, UDL Considerations 2.1 and 2.2 functioned not only as a coding scheme but as an analytic lens that oriented the research team toward specific instructional dimensions (e.g., vocabulary clarification and decoding support) and helped surface patterns that might otherwise have been described in more generic terms. Three findings stand out as especially actionable for instructors: (1) attending explicitly to symbol morphology, including how symbols appear in different handwriting styles, addresses a source of confusion that often goes unacknowledged; (2) offering word-for-word translation between symbolic and natural language gives students a replicable strategy they can apply independently; and (3) making structural relationships among symbols visible reduces the cognitive burden of treating each symbol as an isolated fact to memorize.

Specific instructional strategies included developing lists or glossaries of key terms, consistent with Bailey (1999). This allows students to recognize the morphology of the symbol while attaching meaning and significance to it. Additionally, tools like a Frayer model graphic organizer invite students to observe how symbols interact with context as they record examples and nonexamples of uses of specific symbols. Oyoo (2022) recommends "multiple representations may be given considerable priority as its linkage to other situations of use is indispensable" (p. 127). Students find that symbol translations without context are not useful - "you can't just Google it" (Avery).

Instructors play a pivotal role in developing students' understanding of symbols. As Esuong and colleagues (2022) conclude, "mathematics teachers concentrate on demystifying the abstraction in mathematics by interpreting mathematical statements and sentences into their symbolic notation." Students appreciated this word-by-word interpretation and found the approach helpful to attempt independently. More broadly, there is a recommendation that "meaning must precede symbolization" (Mutodi & Mosimege, 2021, p. 1194). Encouraging students to express ideas in natural language before encoding them in symbols was something that students and instructors both mentioned. This is consistent with recommendations that building connections between informal and formal language helps students develop symbol sense (Mutodi & Mosimege, 2021).

Insight into how instructors can communicate the symbology ecosystem to their students was evident in Dr. Landry's classroom episode. Dr. Landry recognized that expert knowledge included appreciating the structure and organization of the assignment of symbols to ideas in statistics. Dr. Landry's attempts to communicate relationships between symbols appears to be an attempt to reduce the cognitive load required for students to distinguish between multiple symbols that express related ideas. While researchers seem to agree that learning symbology increases students' cognitive load as students hold multiple ideas simultaneously (e.g., Begg & Pierce, 2020), a strong symbol sense "accommodates new mathematics cognitive demands" (Mutodi & Mosimege, 2021, p. 1195). Dr. Landry seems to be reducing the cost of learning symbols by investigating structure and organization so that the reward of increased symbol fluency can come more naturally to students.

It is worth noting that this study documents instructional practices and students' perceptions of those practices—not learning outcomes. Students' reports of feeling less intimidated by symbols, and of developing strategies to make sense of them, represent meaningful evidence of increased access and engagement with statistical ideas. Whether those experiences translated into deeper conceptual understanding is a question for future research.

Conclusion

The diversity of student cognitive profiles and prior experiences in secondary mathematics courses increases the demands on postsecondary instructors to create responsive and effective learning environments. The Universal Design for Learning framework offers recommendations for designing environments that identify and mitigate barriers students may face. This article offers detailed accounts of student and instructor perspectives on specific practices that align with UDL Considerations 2.1 and 2.2, addressing challenges students may face in understanding symbols.

As qualitative research, this study provides thick, rich description of the lived experiences of the study participants (Creswell & Miller, 2000). Along with that depth comes the limitation of transferability to novel contexts. This study relied on student volunteers at a single institution along with their instructors. The institution's context may limit the generalizability of these findings; most institutions do not have as high a proportion of students who report learning and attention differences. Furthermore, the faculty at Curry College may possess distinct teaching philosophies and employ more student-centered instructional strategies compared to faculty elsewhere.

Future research could examine the ways instructors align their instruction to these UDL Considerations in other course subjects and at different institutions. The qualitative research methods employed in this study provide deep insight into how students and instructors experience the teaching and learning environment.

DIMINISHED FEELINGS OF BELONGING IN AN 8TH GRADE MATH CLASS

Amy J. Hackenberg

Hyunjeong Lee
Utah Valley University
Hlee@uvu.edu

This classroom study describes an experienced eighth grade teacher's actions to support students' feelings of belonging in his Math 8 classroom over an academic year, based on his involvement in a professional development (PD) project to support those efforts. The teacher made progress toward the goal to support belonging with emotional decentering. He identified that validating students' contributions in class was essential to support their feelings of belonging. However, in his classroom he often did not validate cognitively—and so he often undermined this validation. Ultimately, the lack of validation contributed to frayed relationships with some students, which diminished their feelings of belonging.

Keywords: Instructional Activities and Practices; Affect, Emotions, Beliefs, and Attitudes

Feelings of belonging in school are associated with many positive outcomes for students, including engagement, motivation, and learning (Barbieri & Miller-Cotto, 2021; Osterman, 2000). Yet during middle school, students may experience a drop in feelings of belonging (Anderman, 2003). Research has found that student-teacher relationships can positively influence belonging (Booker & Lim, 2018; Maloney & Matthews, 2020). For example, teachers who supported secondary students' feelings of belonging demonstrated emotional consciousness to help students manage frustration, affirmed students as people and thinkers, practiced authentic pedagogy, and showed sociopolitical awareness of care (Booker & Lim, 2018; Maloney & Matthews, 2020). Based on this research, we designed professional development (PD) to support middle school teachers to support their students' feelings of belonging in math classrooms.

In this paper we describe an experienced eighth grade teacher's actions to support students' feelings of belonging in his Math 8 classroom, based on his involvement in our PD. The teacher, Ben Reynolds (pseudonym), identified that validating students' contributions in class was essential to support their feelings of belonging. We found he made progress toward this goal with emotional decentering. However, he was often unable to validate cognitively—and so he often undermined this basic goal. Ultimately, the lack of validation contributed to frayed relationships with some students, which diminished their feelings of belonging. Our research question is: How does a middle school teacher influence students' feelings of belonging in math class?

Literature Review: Belonging in Classrooms

Walton and Brady (2017) define belonging as a conclusion people make about "the quality of fit or potential fit between oneself and a setting" (p. 272). Belonging is experienced as "a feeling of being accepted, included, respected in, and contributing to a setting" (p. 272). Overall, in studies with middle school students, researchers have found a sense of classroom belonging to be positively correlated with motivation (Goodenow, 1993) and academic enjoyment (Sakiz et al., 2012). Feelings of belonging have not been found to directly influence achievement, but they do so indirectly by influencing motivation (Osterman, 2000). However, Barbieri and Miller-Cotto (2021) found that a sense of belonging to the academic community of mathematics was the only factor that predicted middle school students' algebra learning in a unit on quadratics. They also found that under-represented minority students reported lower belonging than other students.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

So, what influences middle school students' feelings of belonging? In a sample of 353 students at a suburban, predominantly White middle school, Goodenow (1993) found that students' perceptions of their teacher were "the most influential single component of belonging and support in terms of association with effort and achievement" (p. 37). Other researchers concur that student-teacher relationships are pivotal in supporting students' feelings of belonging (Booker & Lim, 2018; Harris-Thomas & Roseth, 2025; Maloney & Matthews, 2020; Sakiz et al., 2012). For example, Booker and Lim (2018) found that strong relationships and engaging pedagogy supported eight high achieving sixth grade African American girls to feel like they belonged in math classes taught by White female teachers. Maloney and Matthews (2020) found that secondary school teachers with more productive patterns of caring for students had emotional consciousness, a holistic view of students as mathematical thinkers and people, a collective struggle orientation, and a sociopolitical awareness of care. Students whose teachers demonstrated these characteristics were more likely to feel a sense of belonging in math class, which in turn positively influenced students' valuation of math and perceptions of the relevance of math instruction. Yet, studies have also shown a decline in perceived teacher support across middle grades students (Reddy et al., 2003). We now discuss mathematics teacher learning and decentering, a tool we use to frame teaching practice to support feelings of belonging.

Theoretical Framework: Mathematics Teacher Learning and Decentering

Like many others, we view high-quality mathematics teaching to be facilitated by high leverage practices that are implemented consistently over time (e.g., Grossman et al., 2009; McDonald et al., 2013). For example, leading a discussion is a high leverage practice that consists of many smaller practices such as anticipating students' thinking on a task, monitoring student work, and selecting and sequencing student work to support a learning goal (Jacobs & Spangler, 2017; Smith & Stein, 2018). In our view, this perspective on high-quality teaching has to include a theory of how students learn mathematics in order to guide practices such as formulating learning goals, anticipating student thinking, anticipating questions for students, and enacting that questioning in small group and whole class interactions.

Our theory of students' mathematical learning is centered on how students organize and reorganize their ways of thinking in ongoing interaction in their experiential worlds (von Glasersfeld, 1995). Social interaction in classrooms is essential in this view of learning because it provides a critical site for organizing activities that can provoke learning (Steffe, 2010). So, our theory of high-quality mathematics teaching is an interplay between high leverage practices and how students learn, where each informs the other.

Following Silverman and Thompson (2008), we frame a core of teacher learning to be teachers constructing and refining their own first-order knowledge and then constructing and refining second-order knowledge of their students. We refer to people's own ways of thinking as their first-order knowledge, which they construct to organize and understand their experiences (Steffe, 2010). Second-order knowledge refers to the knowledge a person constructs to describe and explain their observations of another person's experiences (Steffe, 2010). In turn, constructing second-order knowledge requires decentering (Bas-Ader & Carlson, 2022). Decentering involves setting one's own perspective to the side, working to adopt the perspective of another person, and using that perspective as a basis for interaction. In decentering from one's own perspective, one necessarily centers others' perspectives.

Decentering and centering can support students' feelings of belonging. For example, to demonstrate Maloney and Matthews's (2020) emotional consciousness with students, teachers need to set their own emotional experiences aside, work to understand their students' emotional

experiences, and interact with them from that basis. In this process, teachers do not assume that students' emotions are similar to their own. Instead, they aim to understand students' emotions and interact with students from that understanding, thereby centering students' experiences.

Decentering cognitively has not been addressed in studies on belonging in math classrooms, but it is an important part of mathematics teacher learning (Carlson et al., 2024; Silverman & Thompson, 2008). In cognitive decentering, teachers set their own ways of thinking aside, work to understand their students' ways of thinking, and interact with them from that basis. When a teacher interacts with students based solely on their own first-order knowledge, they may not see students' thinking, let alone center it in the classroom. In contrast, when a teacher does not assume that students think as they think, and seeks to understand how they think, the teacher is beginning to build second-order knowledge and has a chance of centering it.

Method

Participants

To support a middle school teacher to support his students to feel a stronger sense of belonging in math class, we conducted a 10-month classroom study with eighth grade teacher Ben Reynolds and one of his classes. The classroom was in a middle school located in a small town in the midwestern United States. Ben was White and was chosen because he agreed to participate. He had 14 years of experience at the time of study and taught Math 8 and algebra.

We conducted the study with Ben's Math 8 students because we thought Math 8 students might vary more in their feelings of belonging in math class compared to algebra students. Sixteen of 25 students in the class consented to participate, which meant they took surveys and assessments and participated in a focus group if asked. They also shared their work with the research team. Of the participating students, one student was Black; the other 15 were White.

Data Collection and Professional Development

In August, Ben participated in an initial interview. We sought to understand Ben's teaching and his initial ideas about belonging. Then we asked him to choose two of four PD foci for our work together: students' reasoning, math talk, social and emotional learning, or students' histories and cultures. He chose students' reasoning and math talk. We had a PD meeting approximately monthly to work on some facets of these chosen foci. In between meetings, Ben worked on an aspect of his practice related to that focus. A 4-person research team observed his class weekly and filmed monthly. Then at our next PD meeting, we debriefed, noticed and wondered, and planned for the next stretch of time (Goldsmith & Seago, 2011). At subsequent PD meetings, we reviewed artifacts, such as student work or segments of audio or video from the recently filmed class, in order to develop the current aspect of practice Ben was working on and to ground our observations in evidence.

We observed Ben's 75-minute Math 8 class every Friday from August to May and took field notes. We filmed six class periods and six PD meetings almost monthly by May (Figure 1). In the May class, students designed a brochure and did not engage in mathematical thinking, so we omitted that from our analysis. In May we conducted a final interview with Ben.

Month	Aug	Sep	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May
Meetings with Ben	Initial Interview	PD 1		PD 2		PD 3	PD 4	PD 5	PD 6	Final Interview
Math 8 Class			Class 1		Class 2	Class 3	Class 4		Class 5	Class 6

Figure 1: Project Timeline of PD Meetings and Filmed Classes

The 16 participating students completed a survey about their feelings of belonging in September, January, and May. We used the survey from Maloney and Matthews (2020) with three criteria each addressed with three items (Figure 2). Students had a choice of six responses from 1–Strongly Disagree to 6–Strongly Agree. Some students participated in focus groups in November, January, and May, each consisting of 3–7 students.

Emotional support from the teacher	My math class is like a family	My contributions are valued
• I feel that I can talk to my math teacher(s) about things that are bothering me. • My math teacher is someone I can count on to help me. • I believe that my math teacher(s) is/are interested in the things I have to say.	• Students in math class help each other, even if they are not close friends. • When I do well in math, the other students in class are usually happy for me. • My math class is like a family.	• My math teacher(s) know that I can do good work. • I want my math teacher(s) to be proud of my work. • I have a lot of opportunities to get involved in my math class.

Figure 2: Nine-Item Survey from Maloney and Matthews (2020)

Data Analysis

To analyze the data, we engaged in rounds of coding of four sets of video data: the filmed class meetings without May (5), the filmed PD meetings (6), Ben's interviews (2), and the student focus groups (3). Each video data source required a unique codebook, although there was some overlap in the codes for class and PD meetings. Many codes arose from constant comparative analysis, as there is not much research on supporting feelings of belonging in math class in middle schools. However, we also used relevant codes about decentering (Bas-Ader & Carlson, 2022). Both authors of this paper coded each piece of data, discussed coding, and ran intercoder analyses until we reached over 90% agreement. As we stabilized coding, we developed 12 categories that described key features of the filmed class meetings. Then we examined the field notes from the Friday observations (28 additional non-filmed class periods) to determine whether these categories were evident in other classes and to search for disconfirming evidence. We developed categories for the PD meeting data and summaries for each interview. Once all categories were stable, we used them to develop themes from the data.

We coded the student focus group data with constant comparative analysis, created a summary of key ideas for each group, and tracked how students' concerns changed over time.

Finally, to analyze students' belonging survey data, we computed descriptive statistics. We tested the normality of our data using the criteria that the kurtosis and skewness should have an absolute value less than 2 (Strunk & Mwavita, 2025), and they did. Plots showed most data to be approximately normal, despite the small sample size. So, we decided we were justified in running parametric tests (Harpe, 2015). We ran a repeated measures ANOVA to test for differences over three time points for each of the three criteria.

Findings

We respond to our research question—how a middle school teacher influenced his students' feeling of belonging—in three parts: Decentering and relationship-building (Fall), lack of cognitive decentering (Fall-Winter), and fraying student-teacher relationships (May). Due to space limitations, we have to summarize some parts significantly.

We begin with a brief portrait of Ben's teaching to provide context. When asked to describe himself as teacher, Ben said in the last 5 of 14 years he had moved from a competitive, computation-focused atmosphere to a relationship-building atmosphere, where he strove to get to know his students. He said he wanted students to become critical thinkers and develop a growth mindset. Ben had, over time, culled many class activities and problems that drew from a variety

of websites, including 3-Act Problems, Desmos, as well as more traditional worksheets. He sometimes used engaging, complex problems that would be classified as "doing mathematics" (Smith & Stein, 2018, p. 16). Ben did not follow a traditional text. In his class, desks were in rows, but students in the same row were in groups that consisted of 2–4 students who worked together at times. He changed these groups a couple of times during the year. During his initial interview, as well as repeatedly over the year, Ben stated how much he loved it when a student pointed out a way of thinking about an idea or problem that he had not thought of before. This often happened during the 3-Act Problems.

Fall: Decentering and Relationship-Building

In the fall, Ben primarily showed evidence of decentering and relationship-building with his students. For example, in October Ben led a number talk to start class: 12 x 25. Students were quiet, seeming reluctant to participate although they had done number talks before. Ben repeatedly and gently acknowledged that the quiet might come from students feeling like they were wrong. Eventually students shared answers of 300 and 250. A student explained that he got 300 by multiplying 25 x 10 and 25 x 2. Other students agreed. When Ben asked about another strategy, students did not respond. So, Ben ended up sharing the idea that you could count by quarters 12 times to solve this problem or count by groups of 50 cents or dollars. It turned out that the student who got 250 counted by 25s six times and got 125 instead of 150. So, this showed evidence that Ben was demonstrating ways of thinking that students had or could make sense of, an example of cognitive decentering. And, Ben decentered emotionally: He imagined the students' emotional reticence to share as distinct from his and tried to reassure them.

Indeed, the November focus group consisted of three students who were very positive about Ben. As one of them said, "he is very patient for a teacher." They said that at first Ben thought like a college student would think but then he will "do it in a way that eighth graders will understand." Their views demonstrate what seemed apparent in class to this point: Overall, the students trusted Ben and thought he was doing a good job as a teacher. These three students' comments were also positive about the class and their position in it. That said, over the year we found that these three students were among the stronger mathematical thinkers in the class. And, two of these students felt a strong sense of belonging over the year: They had the two highest averages on the survey criteria "*emotional support from the teacher*" and "*my contributions are valued*," and one had the highest average on "*my math class is like a family*." So, this focus group might not have been representative of the class as a whole.

Fall and Winter: Lack of Cognitive Decentering

In fact, in the fall Ben self-reported an interaction with a student, Kari, that pointed to a lack of cognitive decentering. We go out of chronological order here to make this point, discussing data from the September PD meeting. In that meeting, the research team presented results from the students' September belonging survey data. We noted that Kari, who had shown some struggles with ideas in class, had fairly positive scores. Kari was White. Ben said he wondered what she thought after today's class, where they were working on writing numbers in scientific notation. He had put up 107.23 and asked where to put the decimal point to express it in scientific notation. He said when he asked questions about what seemed like "simple concepts" to him, he called on students who "need a little more confidence." However, Kari could not tell him where to put the decimal. He said his strategy in these cases is "to repeat things if necessary; maybe she was zoning out; maybe she was thinking about a boy, or thinking about whatever." He restated the question multiple times, but she did not get it. He noted, "And I'm like dying, trying to get her, and she's getting frustrated and [I said] okay, we'll come back to you."

In our view, this interaction can be explained by a lack of second-order knowledge of Kari's ways of thinking about decimals. Specifically, we are not sure what Ben was relying on to simplify his question—what question or idea qualified for him as simpler. We suggest that he was trying to think from Kari's perspective socially and emotionally by wondering about her zoning out or thinking about a boy, but not from her perspective mathematically. Decimals are notoriously challenging because constructing them relies on operations involved in constructing fractions (partitioning, iterating, etc.), repeated partitioning of units into units that are ten times smaller, and relating those units (e.g., Borowski, 2020; Kosko et al., 2026; Wearne & Hiebert, 1988). It appears that Ben's simplification did not meet Kari's current thinking about decimals.

In fact, this self-reported interaction was a harbinger of things to come: Ben continued to demonstrate a lack of cognitive decentering with Kari and her partner Blair in the winter. For example, in December students worked on Turtle Time Trials, a Desmos activity where initially two turtles raced and then later a third turtle was added. Students were asked about the speed of the turtles, filled in distance values in a table with distance and time values, and then looked at a graph of each turtle's distance and time values (Figure 3). Turtle 1 traveled six feet in six seconds; Turtle 2 traveled 12 feet in four seconds; and Turtle 3 traveled 12 feet in eight seconds.

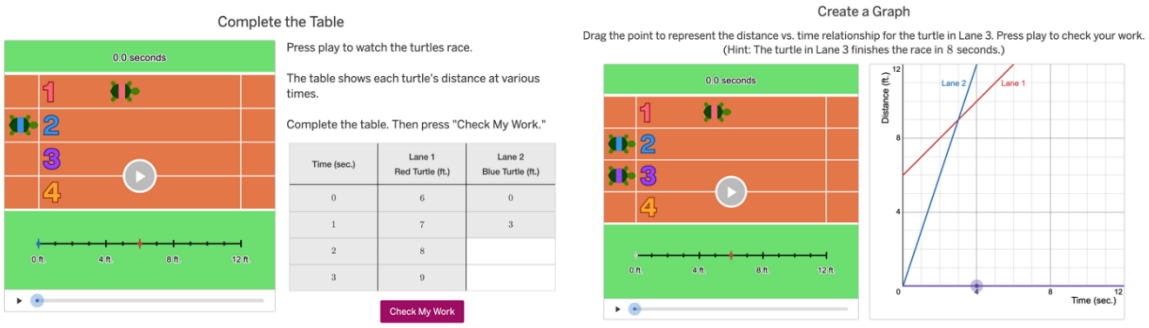

Figure 3: Turtle Time Trials

Students were asked which was faster, Turtle 1 or Turtle 3. Blair and Kari asked Ben about this question, and Ben asked what they had found. Blair said, "We said they had the same." Ben asked, "So how are you determining who is the fastest?" Blair described what they saw when they watched the race, stating, "they just look like they were going the same." Ben then repeated the question about how they were deciding how fast a turtle was, and he pointed them to the formula for speed that was on their worksheet, "speed = change in distance/change in time." Kari described what they had done for the table, where they watched the turtles race, saying, "we did 3, 6, 9" (Figure 3, left). She did not say what these numbers meant in the situation (distances in feet for Turtle 2). Ben interpreted this as them following a pattern. Then he steered them back to the formula and again asked which turtle would be going the fastest. When the students did not seem sure, Ben pointed them to a graph on a later slide (Figure 3, right) and directed them to use that. The students said they did not know how to. He then led them through using the graph.

Here, Ben appeared to assume that when the two students filled in the table, the numbers they wrote down meant distances to them. He also seemed to take for granted that they were tracking elapsed distance and elapsed time, an essential component of conceiving of speed (Hackenberg et al., 2023; Thompson & Thompson, 1994). Ben did not ask them to think about what the numbers meant and how they were related to the turtles' movements. For example, in the race and table (Figure 3, left), it is possible to see that Turtle 2 travels three feet in the first second,

and then another three feet in the next second, and then another three feet in the third second. So, the turtle is traveling three feet every second. It is not necessary to use an equation to figure that out—but it is necessary to focus on how distance in feet and time in seconds are changing together as Turtle 2 moves. Instead, Ben focused on an equation and graph that had meaning for him but not necessarily for students who are building ideas about speed. As teachers have done before him, he treated speed more as a calculation than as a quantity that needs to be constructed (Thompson & Thompson, 1994). This was one example of a phenomena that happened often in the spring.

May: Fraying Relationships

One outcome of the year was that Ben's relationships with Blair and Kari, as well as some of the other students, seemed to fray. For example, in the May focus group with six students, all said they could count on Mr. Reynolds to help them with math. However, when asked whether Mr. Reynolds understood how they thought about problems, Blair said, "probably not." Two students said that if they got something wrong and he tried to explain and they still didn't get it, he got kind of frustrated. Kari said that Mr. Reynolds "understands it how like a higher student understands it." Furthermore, Blair, Kari, and another student said they did not feel comfortable asking him questions. When asked who they went to with questions, they said their groups.

These feelings about Ben were born out in the belonging survey data. The means for *"emotional support from the teacher* and *my contributions are valued"* decreased significantly from September to May (4.35 to 3.02, with $F = 23.286$, $df = 2$, $p < .001$; and 4.62 to 3.87, with $F = 6.406$, $df = 2$, $p = .005$). Partial eta squared was 0.625 and 0.314, respectively, which indicate large effects. However, over the year there was a statistically significant increase in the means for *"my math class is like a family"* (3.0 to 4.6, $F = 17.941$, $df = 2$, $p < .001$). Partial eta squared with 0.562, also a large effect.

Taken together, we can say that students' feelings of belonging decreased on two criteria and increased on one. The teacher has influence on all three criteria, especially emotional support from the teacher. Thus, fraying relationships with teacher detracted from students' feelings of belonging. However, other students have influence on the criteria my math class is like a family. So, despite the fraying relationships, students experienced an increase in that aspect of belonging. Since students were feeling some dissatisfaction with Ben, it is possible that they bonded with each other partly in opposition to a teacher they some felt increasing distance from.

In the final interview, Ben identified that validating students' contributions in class was at the heart of supporting students' feelings of belonging. About a student contribution in class, he said: "You have to do your best, even though it's very difficult sometimes, to find a way to tie it in and give value to that and make them feel like their response was worth something." However, he acknowledged that he did not always pose problems that were sensible to students and that he needed to provide more supports. He noted that he used to teach the math support class at the school and enjoyed that because he had the time to "meet [students] on their level."

Then Ben reiterated that some of his favorite moments in teaching were when students came up with ideas he had not thought of: "you're like, mind blown, you love it. And so the student thought side of it, why are their brains thinking that this is the connection, or this isn't, or how do they not see this or whatever? It is really interesting." Here Ben spoke about how he loved understanding an idea that a student had that was new for him. In fact, his question about students' brains is a question about second-order knowledge. So, Ben seemed to see a strong need for this kind of teaching and for connecting with students' ways of thinking: He found it enjoyable; and he learned new ideas from students. However, when asked what he had learned

from his students this year, he paused. Then he said he did not know that he had learned anything new compared to prior years. Our interpretation is that despite his appreciation of students' thinking, he did not seem to have a way to regularly surface and learn it. He did learn from students, but it was rare at this point, now 15 years into his career.

One outcome of this situation was that Ben could not fully follow through on his goal to validate what students shared with him as a key piece of supporting their feelings of belonging. The reason, in our view, is that to do so requires awareness of students' first-order knowledge as distinct from one's own—as second-order knowledge to build and use as a basis for interacting. We argue that to think about students' knowledge in this way requires an orientation to do so, as well as ideas about what that second-order knowledge could be, such as understanding that students may not be constructing quantities of distance and time, let alone co-varying them, as they watch a race. This learning requires sustained professional support (Carlson et al., 2024).

Discussion

We have shown that Ben was unable to fulfill what he held most dear as a teacher, and what he identified as the heart of supporting feelings of belonging, because of a lack of cognitive decentering. We argue that this was a factor in the fraying of student-teacher relationships, which in turn diminished students' feelings of belonging in the class.

In terms of prior studies, Ben often practiced authentic pedagogy as described by Booker and Lim (2018): He posed complex problems, did not follow a textbook, and frequently used technological tools like Desmos. He also had strong relationships with some students as shown with the November focus group. Ben regularly demonstrated emotional consciousness (Maloney & Matthews, 2020) via decentering emotionally. He was seen as a trusted teacher by many, particularly in the fall semester.

And yet, these characteristics were not enough to support Ben to validate all students' responses in class, the heart of belonging for him. We found that he could sometimes validate the responses of students who had more basic ways of thinking than he would use, as shown during the number talk in October. But it was challenging for him to validate some of his students' responses, as was repeatedly evident in his interactions with Kari and Blair. So, our study suggests that decentering cognitively is a tool to support validation of students' responses in math class that in turn may support students' feelings of belonging—or at the very least, can support strong student-teacher relationships (Hackenberg, 2010). This aspect of teaching has not been unearthed in prior studies about secondary math teachers and belonging (e.g., Booker & Lim, 2018; Maloney & Matthews, 2020). So, this is one contribution of our study.

This study is limited by being a single case. The study was designed to be conducted with multiple teachers. Data collection occurred just as the country was emerging from the pandemic, and we only were able to secure one participant. From this study we cannot make claims about other teachers and classrooms, but it can provide an important foundation for further research.

Based on our study, we conjecture that cognitive decentering plays an important role in supporting students' feelings of belonging in middle school math classrooms. We propose that learning to decenter cognitively requires developing an orientation to value this type of responsiveness, along with new ways of thinking that reflect the mathematical thinking of students (Carlson et al., 2024).

A good question is: How can this work be done in classrooms, when middle school teachers meet over 100 students a day? Our response is: It cannot be done with all of those students at once. However, most middle schools have math support classes for students who struggle. We

think those classes are a potent opportunity for teachers to practice cognitive decentering with support for their professional learning. We are eager to try this in our local settings.

A FRAMEWORK TO CONCEPTUALIZE ADAPTIVE TEACHING IN MATHEMATICS EDUCATION: THE ADAPTIVE TEACHING TETRAHEDRON

Sarah Hartman
Middle Tennessee State University
seh7s@mtmail.mtsu.edu

The ability to adapt to the unexpected in the classroom is an important skill for all teachers to possess. This skill, adaptive teaching (AT), is under-theorized in mathematics education and suffers from a lack of consistency in definition. In this essay, I propose a conceptual framework called the Adaptive Teaching Tetrahedron (ATT) that is built upon themes from existing literature. The framework was developed through an iterative hermeneutic phenomenological process and conjectures a relationship between various literature bases in and around AT. Implications for the mathematics education research and teaching community are presented.

Keywords: Teacher Knowledge, Instructional Activities and Practices, Teacher Educators

The classroom environment is a complex and messy system. The preparation to teach effectively within this type of environment has been debated by mathematics education researchers for decades. Now, with the rise of scripted curriculum and new policy mandates (Vaughn et al., 2022), new standards, and diverse student situations (Parsons et al., 2018), teachers are required to *adapt* to a variety of circumstances to provide quality instruction. Further, adaptive mathematics instructors understand the complexities of student questioning and discourse, can elicit student thinking and the intricacies of various solution strategies, and use student-centered instruction to promote their students' learning (National Council of Teachers of Mathematics [NCTM], 2014). As student-centered instruction is becoming increasingly central to K-12 education, novice teachers may feel unprepared to meet the demands of being an adaptive mathematics instructor (Darling-Hammond, 2006). Adaptive teaching is a 'gold standard of instructional practice' (Darling-Hammond & Bransford, 2005; Parsons et al., 2018) that warrants the attention of the mathematics education research and teaching community. Despite the growing recognition of the importance of adaptability (Gallagher et al., 2022; Parsons et al., 2018; Remillard & Heck, 2014; Vaughn et al., 2016), there remain gaps in both the empirical study and explicit definition of adaptive teaching, especially within mathematics education. Literature has indicated various common aspects of adaptive teaching (Randi, 2022), yet has not conjectured a relationship between these aspects in the actions of adaptive teaching.

In this article, I propose a conceptual framework of the components of an adaptive mathematics teacher that builds on existing literature and incorporates mathematics education-specific components. The goal of this article is to propose this framework to the field of math education as a way to reconceptualize what it means to adaptively teach. Lastly, I call attention to the need for further study of adaptive teaching.

What is Adaptive Teaching?

This research topic is dense with entangled terms, which can make adaptability difficult to define. Loughland (2019) describes that adaptive teaching "suffers from a lack of consensus on a common term, although there is agreement that adaptive teaching, by any other name, involves a response to a range of stimuli provided by their students" (Loughland, 2019, p. 17). In addition, some researchers view adaptive teaching as only happening within the classroom in response to an unexpected stimulus (Gallagher et al., 2022) that supports student needs (Parsons et al., 2018),

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

while others conceptualize it as a disposition towards teaching and a mindset both in and out of the classroom, coupled with specific practices (Corno, 2008; Loughland, 2019).

Despite this, literature has documented what an adaptive teacher looks like. Responding to students' thinking, attending to students' needs, and handling classroom complexity with flexibility are all features of adaptive teaching (Corno, 2008; Darling-Hammond & Bransford, 2005; Parsons et al., 2018). Adaptive instruction is responsive, reflective, and creative (Randi, 2022). The adaptive teacher effectively uses student thinking to progress lessons and adapt to their environment (Lin et al., 2007). Adaptive teachers assess students in the moment using content expertise, all while maintaining a flexible mindset (Randi, 2022). Likewise, effective teachers adapt to sociocultural contexts (Herbst & Chazon, 2017; Franke, 2007) and view variation among learners as an opportunity (Beltramo, 2017; Corno, 2008; Schipper et al., 2018). Adaptive Teaching has been referred to as a component of effective teaching (Vaughn et al., 2022) but has rarely been discussed or theorized explicitly in mathematics education.

Herbst and Chazan (2017) argued for increasing the subject specificity of research in mathematics teaching. Researchers such as Prediger (2022), Parsons et al. (2018), and Gallagher et al. (2022) emphasized that adaptability may not be fully understood or implemented without considering the content-specific demands of the classroom. By incorporating subject specificity into theoretical models about adaptive teaching, the mathematics education community can move toward investigating what it means to better prepare teachers to make contextually appropriate adaptive decisions, thereby building more responsive and effective teaching practices.

The definition of adaptive teaching I will use throughout this article is when a teacher adapts their instruction in such a way that it attends to content, knowledge of students and their thinking, and the pedagogical demands of the situation (Darling-Hammond & Bransford, 2005; Hoffman & Duffy, 2016). The adaptation, then, is a high-leverage move that is specific to the needs of the learners in the moment (Vaughn et al., 2022). A high leverage move is one that significantly alters the progression of the lesson to meet the needs of the students, whether that be cognitively, behaviorally, or situationally (Martin et al., 2012). In a mathematics context, the needs of the students are tied to the mathematics at hand.

Examples of adaptive teaching in math education are slim. One example in another discipline is described by Parsons and Vaughn (2013). Parsons and Vaughn (2013) observed two teachers' adaptive instruction. They describe a teacher, Ms. Bradley, who was focused on literacy and social studies education. In one instance, Ms. Bradley "adapted her instruction by initiating a discussion about how certain groups of people were left out of history: women, African Americans, Native Americans, and slaves." (Parsons & Vaughn, 2013, p. 310). Parsons and Vaughn (2013) noted that this adaptation was in response to a student contribution. The adaptation was specific to the needs of the learners in the moment, and attended to social studies content, knowledge of student thinking, and pedagogical demands. Although this example is not from mathematics education, it does demonstrate what an adaptation is in this context. The scarcity of examples from literature in mathematics education motivates the need for further study of adaptations in mathematics-specific contexts.

It is for these reasons that I call attention to the need for further study of adaptive teaching in mathematics education. This article presents the Adaptive Teaching Tetrahedron (ATT), a conceptual model built upon synthesized literature that makes visible the relationships between student thinking, subject matter expertise, and adaptive expertise, as well as conjectures some skills needed in teachers to support adaptive teaching. This framework contributes to the literature by positing a relationship between the components of adaptive teachers.

Methodology

For this article, I took a hermeneutic phenomenological approach to theory development (Annells, 2006; Boell & Cecez-Keçmanović, 2014; Creswell & Poth, 2024). A phenomenological approach requires a researcher to identify a phenomenon to study, distinguish the philosophical assumptions of the phenomenon, and then collect data, traditionally from individuals who have experienced the phenomenon. Phenomenology is focused on extracting the essence of a phenomenon across multiple instantiations (Creswell & Poth, 2024). Due to the complexity in definition and conceptualization, this approach was appropriate. Likewise, a hermeneutic approach focuses on the iterative interpretive process of the 'texts of life' (van Manen, 1990). Rather than collecting data from individuals, a literature review was conducted following the framework proposed by Boell and Cecez-Keçmanović (2014).

The framework involves two hermeneutic circles: 1) search and acquisition of literature and 2) and interpretation of the literature. The first hermeneutic cycle of search and acquisition involves acquiring, reading, identifying, refining, searching, sorting, and selecting literature. The second hermeneutic circle of analysis and interpretation includes mapping and classifying literature, critical assessment of literature, argument development, and open research questions. These cycles are intertwined and representative of the fluid nature of literature review, which allows for "the development of new linkages among concepts and theories and new synthesis" (Boell & Cecez-Keçmanović, 2014, p. 264). Boell and Cecez-Keçmanović (2014) argue that the literature review process is fundamentally iterative in nature while developing an understanding of a phenomenon.

Because there is an absence of theoretical advances and understanding of the fundamental relationships between literature bases and considerations involved with adaptive teaching, a hermeneutic phenomenological approach allowed me to synthesize data in the form of literature, generate themes from this analysis, develop textural and structural descriptions to ultimately report a composite description that represents the understanding of adaptive mathematics teaching in a written form (Creswell & Poth, 2024). By using this approach, I was able to extract the invariant essence of adaptive teaching by iteratively interpreting past literature. The result of this process was a dynamic, conceptual model, the Adaptive Teaching Tetrahedron (ATT). Here, I present this composite description along with a conceptual narrative to support the theoretical discussion of the many moving parts of adaptive teaching, specifically in a mathematics education classroom.

Results of Literature Synthesis

As I reviewed the literature on this topic, I found major themes within the literature speaking to what an adaptive teacher is and the types of actions they take. The first theme is Content Fidelity, wherein adaptive instructors adapt with respect to the content at hand. Adapting with Content Fidelity involves knowing how and when to make adjustments to instruction that are consistent with the content-specific components of the lesson. The focus on the content goals of coursework was emphasized in some adaptive teaching studies (Becker et al., 2023; Prediger et al., 2022; Prediger, 2022). Prediger and colleagues (2022) argued that adaptivity is not characterized by teachers moving in a content-independent way. This builds on the work of Parsons and colleagues (2018), who argued that more content-specific teacher moves are needed to fully conceptualize adaptability. Thus, Content Fidelity is an important aspect of adaptive teaching.

A second theme is Adaptive Expertise. Adaptive Expertise (Franyo & Dorner, 2024; Severson-Irby & Parkhouse, 2025; Suh et al., 2023; Suh et al., 2024; Vale et al., 2025; Yoon et

al., 2019) involves adaptive behavior in response to student needs that are 'novel and appropriate' (Hammerness et al., 2005; Randi, 2022). Adaptive expertise involves balancing efficiency and innovation in novel classroom situations (Anthony et al., 2015; Bransford et al., 2005; Riel & Rowell, 2017; Schwartz et al., 2005; Severson-Irby & Parkhouse, 2025). In addition, adaptive expertise draws on prior experience and knowledge (Severson-Irby & Parkhouse, 2025), which enables pedagogical practice that is flexible and able to shift to student needs (Anthony et al., 2015; Hammerness et al., 2005; Severson-Irby & Parkhouse, 2025; Hu, 2024; Spiro, 1997). This refers to a teacher's ability to perform creatively and effectively in unfamiliar situations (Severson-Irby & Parkhouse, 2025). Adaptive Teachers act in a way that is true to how and why strategies, techniques, and practices impact their students and environments (Severson-Irby & Parkhouse, 2025), which is a goal for all teachers (Barrett & Hordern, 2021).

A third theme is Student Specific Traits. The social, instructional, and linguistic needs of the student are at the forefront of instructional adaptations. Understanding student responses and in-the-moment assessment of student thinking, as well as the needs of the student, characterizes this theme (Gallagher et al., 2022; Robertson et al., 2016). In prior literature, adaptive teaching practices have generally been regarded as being in response to student need (Gallagher et al., 2022), where adaptive teachers consistently adjusting routines in the moment to meet the needs of students, especially in a content-specific manner (Riel & Rowell, 2017). These three themes summarize what adaptive teachers' actions look like in the classroom.

The Adaptive Teaching Tetrahedron

The ATT (Figure 1) is a conceptual model intended to draw together the ideas present in adaptive teaching literature to provide a basis for future efforts in adaptive teaching. The ATT is composed of the three areas previously described, where Content Fidelity, Adaptive Expertise, and Student Specific Traits form the faces of the tetrahedron. The faces of adaptive teaching represent action, while the edges are fundamental components upon which action is built. Interestingly, I found three other themes about core skills adaptive teachers possess: Formative Assessment, Subject Matter Knowledge, and Improvisation, which form the edges of the tetrahedron. The intersection of the faces and edges reciprocally supports an adaptive teacher's complex navigation of the classroom. The faces in the ATT are actions of adaptive teaching supported by the qualities presented in the edges.

Elaborating on the edges, *Improvisation* (Aadland et al., 2017; Ben-Horin et al., 2016; Holdhus et al., 2016; Thomas et al., 2023; Vinnichuk et al., 2022) refers to a teacher's ability to use premises of effective teaching and content knowledge to make spontaneous, in-the-moment changes to practice (Randi, 2022). Randi (2022) likens this to creative teaching and disciplined improvisation. Improvisation straddles general pedagogic knowledge and pedagogical content knowledge (Holdhus et al., 2016; van Driel & Berry, 2010), and is a fluid response to the constraints of the classroom structures (Holdhus et al., 2016). Subject Matter Knowledge refers to the knowledge that teachers have of the designated subject being taught. This is separate from Content Fidelity because the subject matter knowledge is part of what allows for an adaptation to be content-specific. *Subject Matter Knowledge* is also related to Student Specific Traits because it allows teachers to be faithful to the content they teach, as well as the students' content-specific thinking. *Formative Assessment* refers to the continual, informal, dynamic assessment that occurs both asynchronously and synchronously in the classroom based on elicited evidence of student thinking and understanding to inform pedagogical decisions (Allen et al., 2013; Black & Wiliam, 2009; Corno, 2008; Grigorenko, 2009; Nickl et al., 2024). In sum, each of these themes represents something a teacher would need to be adaptive: knowledge of the content itself, an

ability to improvise instruction, and assessment of student needs and understandings during classroom instruction.

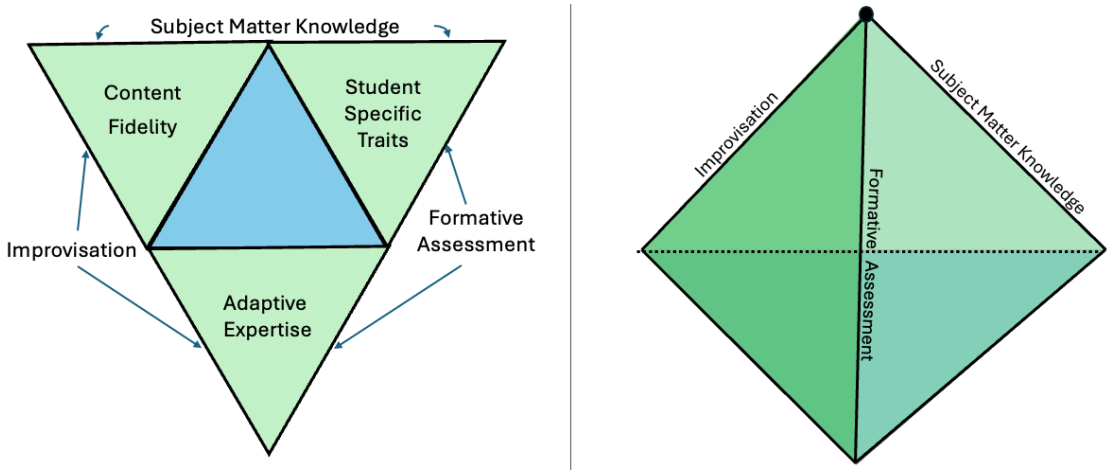

Figure 1: The Adaptive Teaching Tetrahedron

Thus, the ATT includes these three aspects as core components of adaptations. For instance, Adaptive Expertise is defined in literature by improvisation, creativity, and flexibility, as well as the continual assessment of student needs (Severson-Irby & Parkhouse, 2025). Therefore, in the ATT, Adaptive Expertise is supported through formative assessment and improvisation. An action specific to students, Student Specific Traits, is specifically related to content and is based on the students' apparent understanding of the content, which is why Student Specific Traits are supported with both subject matter knowledge and formative assessment. Content Fidelity is supported by improvisation skills and subject matter knowledge. Improvisation and subject matter knowledge support Content Fidelity because students often respond differently to the mathematics than expected, which requires the teacher to be able to improvise instruction with attention to the subject matter.

The nature of the ATT is important to consider. The ATT presents multiple aspects of adaptive teaching that consistently interact and form a complex, dynamic image of the adaptive teacher, who continually monitors and pushes the boundaries of interaction with themselves, their students, and their content (McMillan & Jess, 2021). The ATT is a dynamic entity; As teachers develop with expertise, the competencies and adaptations teachers have and do will subsequently change. For example, scholars emphasize that learning to be adaptive is possible (Granziera et al., 2019; Hardy et al., 2019), and for many pre- and in-service teachers, the edges of the ATT are still in the process of development.

Each component of the ATT supports the other when the tetrahedron is folded, so no one edge or face is independent of another. This is in support of the definition of adaptive teaching, where an adaptation attends to content, knowledge of students and their thinking, and pedagogical demands of the situation. To clarify, in this model, an adaptation is the conglomerate of all three faces. Other constructs and terms researchers use when discussing adaptations or adaptive teaching may not address all aspects of the ATT.

An adaptive teacher, however, would combine each of these aspects during instruction in a self-regulated and metacognitive manner (Randi, 2022). Further, self-regulation and metacognition are two other themes that arose from the literature search. Metacognition and self-

regulated learning (Duffy, 2005; Lin et al., 2007; Corno & Randi, 2005; Randi, 2022; Rowland, 2013) are related to adaptive metacognition (Lin et al., 2007), where teachers regulate themselves to the learning differences of a classroom (Randi, 2022). Adaptive Metacognition specifically concerns the ability for a teacher to adapt their metacognitive thinking to the events of a classroom (Randi, 2022; Lin et al., 2007). Researchers in this area are working towards developing metacognitive thought that indicates when to adapt and work towards developing an aptitude for adaptive teaching (Randi, 2022; Lin et al., 2007). In this same way, a mathematics teacher's metacognition is specific to mathematics itself and continually reflects the mathematical knowledge for teaching (Rowland, 2013) needed for any classroom situation. Furthermore, self-regulation is a vital aspect of adaptive teaching; an adaptive teacher must control their own emotions and thoughts while teaching (Corno & Randi, 2005; Randi, 2022). These components are not included in the tetrahedron because these two themes more readily describe the navigation of the complex environment; though vital to adaptive teaching, these were not included in the ATT. Future research should investigate where these components fit.

Conceptual Narrative

I employed a conceptual narrative as a reflexive heuristic, designed not for empirical analysis but to illustrate and support reflective engagement with the ATT. The narrative was constructed using evidence of adaptive practice in classrooms from literature (e.g., Parsons et al., 2018) and is intended to support the theoretical discussion of the many moving parts of adaptive teaching, specifically in a mathematics education classroom. The narrative follows Kelley, an introductory algebra instructor who uses student-centered instruction regularly. Kelley's classroom is set up in groups, and students are encouraged to participate in class.

On one particular day, Kelley is working with her students on combining like terms. This lesson is at the beginning of her content progression for this unit. She has one of her students come up to the board and solve the following expression for y: $x^2 + y = 4x^2 + 2$. After subtracting the x^2 term from both sides, the student combines the $4x^2 - x^2$ term into $3x^2$. As the student is writing this on the board, another student raises their hand and asks, "Well, they don't have the same coefficient, so how could we do that step? Why does that work?" Kelley ponders the question, recognizing that the student does not understand what it means for something to be a like-term. Kelley then reflects and realizes this is a common issue for many students. Kelley responds, "That is a great question. Does anyone know how to answer it?" The student writing on the board stumbles and says they do not know. Silence covers the class. Eventually, a student in the back of the class raises their hand and says, "Well, maybe we could figure it out with a picture or something." Kelley has a choice to make: does she follow this student's idea and sacrifice her lesson plan, or answer the question for the class? Kelley recognizes the importance of understanding what a like-term is for the rest of her students' math career, but she did not plan for this. She wants to do something that engages all the students in a discussion about math and remembers that the whiteboards would allow the class to see each other's work. Kelley responds, "That is a great challenge! Ok, everyone, in your groups, see if you can model this process using a picture, and when you have something, send a representative to the board to draw it." During this time, Kelley circles the room observing student work and passing out markers. She notes which students are on the right track and which are not. Soon, every group has a visual on the board. Most of the groups have a representation similar to one x^2 term being subtracted from 4 of an x^2 term, but not every group does. Two of the groups, in a similar variation, chose to use the exponent to combine like terms, and wrote a picture dictating $4x^2 - x^2 = x^6$. The thinking behind this was difficult to see, especially through the representation the students in this group

chose to make, and Kelley struggled to see where the students were coming from. Kelley asked two groups to explain their pictures: one group with the first representation (Group A), and the other from the second set of variations (Group B). After this, Kelley posed to the whole class, "which representation best matches what a like term is, based on the notes you took yesterday?" The students shuffled, found their notes, and began reading when someone from Group B said "wait… we didn't realize it was 4 copies of the same thing… is that what the $4x^2$ means?" Another student chimes in and says "yeah I think so… because 4 – 1 is 3 and the definition of a like term depends on the exponent because I don't think you can mess with the exponent." The rest of the students start to nod, and Kelley asks again which representation best matches the definition of a like term. The students unanimously agree that Group A is the correct representation. Kelley thanks the student who suggested using a visual representation and provides a summary of what the class just discussed, along with another example of the same idea, being sure to use pictures similar to those of her students to explain and continues with the lesson.

Discussion of Narrative

The adaptation described here is Kelley's choice to use the whiteboards in this classroom to show students' thinking and engage her students in exploring mathematical ideas. This move was not planned, and it significantly altered the course of the lesson. In addition, the adaptation was focused on content, knowledge of students and their thinking, and pedagogical demands of the situation, and was subsequently made with content fidelity, student-specific traits, and adaptive expertise. More specifically, Kelley reasoned that her students needed to know and understand what a like term was, but ultimately, her adaptation was based on where her students were in the lesson. In addition, the adaptation followed a student's contribution to mathematics. Thus, the adaptation was made with respect to student-specific traits. Secondly, the adaptation allowed student mathematical thinking to be seen in multiple representations and progressed the lesson towards collective mathematical reasoning. In this way, the adaptation possessed content fidelity. Lastly, the use of whiteboards is indicative of the application of professional knowledge and classroom constraints that ultimately allowed the adaptation to be successful, noting the mathematical benefits of using the whiteboards. Thus, Kelley demonstrated an adaptation with adaptive expertise. The edges of the ATT were also present while Kelley adapted. Kelley had to think on her feet and pivot to whiteboards to make use of the classroom structures; Kelley improvised. In addition, part of the reasoning for the adaptation was based on Kelley's content knowledge of past, current, and future mathematical needs of her students; Kelley used subject matter knowledge. Lastly, Kelley used formative assessment of her students both before and after this adaptation to create an adaptation specific to her students' needs.

Ultimately, Kelley adapted to her students' need to provide high-quality mathematics instruction that is effective and equitable because it allowed all students to engage with and make sense of mathematics (Celedón-Pattichis et al., 2018; Franke et al., 2007). Adaptive teaching is a skill that should be honed for if and when students in a classroom are in need of a change in pedagogy that would promote further mathematical understanding, such as a student in Kelley's class who may be misunderstanding like-terms based on previous instructional moves.

Discussion, Implications, and Limitations

In light of the considerable complexity in existing literature on adaptive teaching and practice of adaptive teaching, new theoretical approaches are needed to understand adaptive teaching and teacher preparation. By highlighting how each theme from the literature is related, the ATT responds to gaps in current theoretical literature to provide a tool that straddles research and

practice. In future efforts, researchers can leverage other related literature bases to fully understand how they are related to the constructs within the ATT. Examples include teacher metacognition (Lin et al., 2007), teacher noticing (König et al., 2022), ambitious teaching (Lampert et al., 2013), differentiation (Tomlinson et al., 2003), teacher flexibility (Leikin & Dinur, 2007), responsive teaching (Robertson et al., 2016), micro-adaptive teaching (Prediger et al., 2022), Building on Mathematical Opportunities in Student Thinking (MOSTs, Stockero et al., 2022), reflection (Schon, 1988), and improvisational teaching (Sawyer, 2011).

Adaptive teaching is not necessarily something that would happen in every lesson taught. In fact, in considering whether thoughtfully adaptive teaching occurs in literacy settings, Hoffman and Duffy (2016) answered *no* on the basis that adaptations occurred very rarely, attributing its lack to scripted curricula. However, provided adaptive teaching is necessary for effective teaching, and adaptive teaching should be developed in teachers, Hoffman and Duffy (2016) describe that teacher educators have the ability to promote adaptive teaching.

The construction of faces using the edges may be a useful conceptualization of task design in methods courses for learning to be adaptive. For example, a teacher educator could work with specific faces and focus on the edges that support them when engaging students in rehearsals (Kazemi et al., 2016). Future research, specifically in mathematics education, is needed to corroborate these ideas. Focusing on developing teachers' ability to make adaptations that are mathematics specific requires teachers to hold a deep understanding of the mathematics itself, the trajectories of the students in the classroom, as well as the connections between those two concepts to ultimately make an adaptation appropriate to content, students, and pedagogical demands in the class (Wang, 2026). This view requires a conceptualization of adaptability specific to the mathematical content.

In addition to a lack of research focused on mathematics education around adaptive teaching, some scholars have called attention to what affordances are in the curriculum that allow adaptive teaching to occur (Vaughn et al., 2022). Following Hoffman and Duffy (2016), future research is needed to understand a) if adaptive teaching is or is not occurring in mathematics classrooms and b) why and how it may or may not occur. Given prior research has shown policy and curricular decisions to be major points of contention for adaptive teaching, on the basis that adaptive teaching is a component of effective teaching (Vaughn et al., 2022), the mathematics education community has the right to further investigate this. Also, The ATT can be used by the practicing teacher who may be looking to improve their practice. The practicing teacher may choose to reflect on their own teaching and investigate how they view their improvisation, dynamic assessment, and content fidelity, and how these skills are reflected in their own teaching.

Limitations of this work include, firstly, that the tetrahedron is a conglomerate of separate literature bases whose connections are, at this point, theorized. The mathematics education community needs to collect data to further explore the ATT and adaptive teaching. In addition, adaptive teaching is a difficult skill to hone. Because of this, its development, while becoming increasingly important, may be difficult to ultimately develop. Secondarily, more research is needed to understand where self-regulation and adaptive metacognition fit with the ATT and adaptive teaching. For the mathematics education community, it is important to consider what support teachers need to be adaptive, what supports or constrain the development and presence of adaptive teachers at all grade levels, and where related literature bases can aid in better understanding adaptive teaching. It is my hope that communicating this framework to the field of mathematics education will spark conversation around adaptive teaching as an important aspect to develop in all teachers.

TEACHING INFLUENCES FOR INSTRUCTORS OF GRADUATE MATHEMATICS

Peter Karanevich
Utah Valley University
pkaranevich@gmail.com

Research on university mathematics teaching has largely focused on graduate student preparation and undergraduate instruction, with limited attention to faculty who teach graduate-level courses. This study examines how instructors of graduate mathematics develop teaching practices. Drawing on a sociocultural perspective (Ball & Ladson-Billings, 2020) and interview data from three faculty members, I analyze instructor-reported influences using a framework adapted from Oleson and Hora (2014). Findings indicate that experience as an instructor is a dominant influence, but its impact varies: for some, it reinforces inherited norms; for others, it prompts experimentation or identity-driven commitments. These findings suggest that teaching development is mediated by identity, affect, and institutional incentives, raising questions about how departments might more intentionally support reflective instructional growth.

Keywords: Teacher Learning, Education in Graduate Mathematics

Introduction / Problem Statement

Research on the teaching of university mathematics has documented the persistence of lecture-dominant instruction, limited pedagogical preparation, and strong inheritance of instructional norms (Bass, 2003; Schoenfeld et al., 2016; Speer et al., 2010). While scholarship has examined graduate student teaching assistants (Deshler et al., 2015; Speer et al., 2005; Musgrave & Carlson, 2016) and undergraduate mathematics instructors (Biza et al., 2014; Coppin et al., 2009; Mesa et al., 2020), considerably less attention has been given to faculty who teach graduate-level mathematics. Graduate mathematics courses play a central role in shaping future researchers, faculty, and disciplinary norms. Yet we know little about how instructors of these courses develop their teaching practices.

Teaching does not emerge in a vacuum. Prior experiences such as those as students, instructors, researchers, and community members, shape how instructors conceptualize the purpose of class time, the role of students, and the meaning of effective instruction. Making these influences visible creates space to interrogate taken-for-granted practices and to imagine alternative possibilities.

This study asks: How are the teaching practices of instructors of graduate mathematics developed?

Focusing on instructor-reported influences, this paper examines how three faculty members describe the experiences that have shaped their teaching. In doing so, it contributes to ongoing conversations about teacher learning in higher education and extends them into the largely unexamined context of graduate mathematics instruction.

Theoretical Framing

This study is grounded in a sociocultural perspective on teaching and learning (Ball & Ladson-Billings, 2020). From this view, teaching is not simply the enactment of content knowledge or technique. Rather, it is shaped by the instructor's histories, identities, relationships, institutional positioning, and the communities in which they participate. Teaching is understood as socially situated practice.

Sociocultural theory foregrounds the idea that instructors' actions are mediated by tools, norms, and prior participation in communities of practice (Lave and Wenger, 1991). Thus, when instructors teach "the way they were taught," this is not merely imitation but participation in historically situated instructional traditions. At the same time, instructors are not passive inheritors of norms; they reinterpret and reconfigure past experiences considering current contexts.

To build an analytic framework, this study draws on categories developed by Oleson and Hora (2014), who identified multiple sources of teaching knowledge in higher education. These include experiences as a student, experiences as an instructor, professional development, interactions with colleagues, disciplinary research, and non-academic influences. Using these categories deductively allows for systematic examination of the range of influences instructors report, while remaining attentive to how they interpret and prioritize those influences.

Taken together, this framing positions teaching development as cumulative, relational, and identity-laden rather than purely technical.

Methods

Design and Context

This study draws on data from a larger ethnographic comparative case study of graduate mathematics education. The broader project included interviews with 14 graduate students, five undergraduate students, ten faculty members, and two postdoctoral scholars, as well as nine graduate mathematics classroom observations and field notes. The present analysis focuses specifically on interviews with three faculty members who teach graduate mathematics courses. Each interview lasted approximately 60 minutes and was transcribed in full.

Participants

To preserve anonymity, participants are referred to by pseudonyms: Hank, Mariana, and Jason. All three are research-active mathematicians teaching graduate-level courses in a PhD-granting mathematics department.

Data Collection

Interviews were conducted either in person or over Zoom and were recorded and later transcribed. Interview questions were not framed explicitly around "influences." Rather, participants were asked questions about their teaching practices, including: "What is the purpose of class time?", "How do student responses influence your teaching?", "How do you typically plan for a class?" Responses to these prompts frequently included reflections on how participants had learned to teach and what shaped their instructional decisions.

Analysis

Full transcripts were analyzed using a deductive coding scheme based on Oleson and Hora (2014). Their coding scheme included: experience as an instructor, experience as a student, experience as a research, and non-academic experiences. Further, sub-codes of the experience as instructor code included: prior classroom experiences, professional development, reflections on feedback, and interactions with other instructors. I chose to include an "other" code to keep in mind the possibilities of other factors that may not fall neatly into one of the codes listed above. Coding of transcripts focused on identifying both the presence of these influences and the ways participants described their impact. Analytic memos were used to compare across cases and identify patterns.

Findings

Hank: Learning to Teach Through Teaching

Hank's instructional development was shaped primarily by experience in the classroom rather than by formal pedagogical preparation or structured inquiry into teaching. When describing how he learned to teach, he emphasized the near absence of formal support: "None, almost none … We just had a one-hour meeting with the equivalent of the associate chair for undergraduate, who just gave us some tips, and that was it." In the absence of sustained preparation, Hank described drawing on available local models. For example, he adopted elements of a colleague's assessment structure: "[The] format [of] my exams came from [professor], and he had a true-false question in his course, and I thought, oh, this sounds good. I just used it." These comments suggest that Hank's teaching repertoire has developed through accumulated practice and pragmatic adaptation rather than through intentional study of pedagogy. He also articulated a perception that institutional structures provide little incentive to invest deeply in teaching:

> Part of the problem is lack of incentives. So for somebody like me, there's no carrots and no sticks. There's no incentive for me to do anything really apart from my basic job. The university doesn't detectively care if I do a good job or a bad job.

Taken together, Hank's case illustrates how teaching experience itself becomes the primary site of learning. Without structured feedback or institutional emphasis, prior classroom practice—his own and his colleagues'—serves as the dominant influence on instructional decision-making.

Mariana: Identity, Community, and Teaching as Social Commitment

Mariana described a more interconnected set of influences, linking her instructional commitments to her experiences as a student and to her identity within the mathematical community. She explicitly connected her background to her pedagogical goals:

> I'm interested in supporting students who are not necessarily always thought of as the students that will be the leaders in mathematics… Because I just experienced first hand, what it is to have a class structure for other people, you know for other culture[s], for other needs.

For Mariana, prior experiences of positioning and belonging informed her commitment to designing more inclusive classroom structures. She noted directly, "Of course, now, and actually it [background] informs my practice as an instructor." Her descriptions of mathematics as collaborative further shaped her instructional orientation:

> I think one of the nicest things about math is that we work in groups to tackle hard problems, and we each bring a perspective … really in math is a place where you can kind of see it happen quite a bit.

Unlike Hank, Mariana discussed frequent student feedback, active learning structures, and intentional reflection on teaching. Her development as an instructor appears mediated not only by experience in the classroom but also by identity, values, and a vision of mathematics as communal practice. Teaching, in her account, is inseparable from questions of belonging and participation.

Jason: Experimentation Without Structured Feedback

Jason described himself as someone who actively experiments with his teaching. He reported polling students about instructional format and adjusting in response to their input: "I polled them on: do you want to continue with the active learning or do lectures? And the overwhelming response was to switch to lectures." These experiments, however, occurred largely without

formal structures for feedback or mentorship. Although Jason frequently tried new approaches, he did not describe sustained guidance on how to interpret student responses or evaluate instructional impact. Over time, this lack of structured support shaped his orientation toward pedagogy. Reflecting on his experiences, he noted:

> That experience is really pushing me towards this attitude that the details don't matter. There's not some magic way of presenting things that will suddenly make the students understand and make them engaged.

Rather than indicating disengagement from teaching, this statement reflects the challenge of experimenting in relative isolation. Jason expressed a desire to "do a good job" and repeatedly sought student input, yet the primary feedback available to him was immediate student preference rather than longer-term evidence of learning.

His case highlights how experimentation alone may not lead to sustained pedagogical development when instructors lack communities or structures to help them interpret and refine their practice. Experience as an instructor is again central—but its impact depends on the kinds of feedback and reflection that accompany it.

Cross Case Comparison

Across all three participants, experience as an instructor emerged as a central influence on teaching practice while Mariana also expressed experience as a student and personal identity as being factors. Each described classroom teaching itself as a primary site of learning. However, the meaning and impact of that experience varied, and these differences appear connected not only to identity and commitments but also to career stage.

Hank and Jason were veteran faculty members with many years of teaching behind them, whereas Mariana was in her first few years as a faculty member. This distinction matters. For Hank and Jason, accumulated experience appeared to stabilize particular orientations toward teaching. Hank described refining what already worked and drawing from established local norms. Jason described cycles of experimentation shaped primarily by immediate student feedback. In both cases, teaching practices seemed to have stagnated over time. Without sustained external feedback or structured professional development, classroom instruction functioned less as a site of transformative teaching practice and more as a mechanism of delivering content.

Mariana, by contrast, spoke from an earlier point in her faculty trajectory. Her reflections suggested a more fluid relationship to practice. She described actively experimenting with structure, seeking feedback, and intentionally aligning her teaching with her commitments around belonging and participation. While experience was still influential, it had not yet hardened into settled routines. Her case implies that early-career stages may represent a critical window in which teaching orientations are more malleable.

Identity also differentiated the cases. Mariana explicitly connected her experiences of positioning within mathematics to her instructional commitments. Hank and Jason did not foreground identity or belonging as shaping forces in their teaching. Instead, they emphasized pragmatics, experimentation, or institutional structures. Taken together, these comparisons suggest that teaching development in graduate mathematics is mediated by an interplay of accumulated experience, career stage, identity, and access to feedback. The longer one teaches without structured opportunities for reflection, the more instructional norms may become ingrained and less visible as choices.

Discussion/Implications

This study extends conversations about faculty teaching development into the context of graduate mathematics, where pedagogical preparation is often minimal and instructional norms remain largely unquestioned. The findings suggest that experience as an instructor is a powerful force in shaping teaching practice. However, experience alone does not guarantee growth or transformation. In the absence of structured feedback or meaningful incentives, experience may instead reinforce inherited norms and stabilize existing approaches.

The cases also highlight the importance of identity and affect in teacher learning. Mariana's reflections demonstrate how experiences of belonging, exclusion, and disciplinary positioning can shape instructional commitments. Teaching, in this sense, is not only a technical endeavor but also an expression of how instructors see themselves within the mathematical community. Professional development efforts that focus exclusively on technique risk overlooking these mediating factors.

Career stage appears to play a consequential role. Early-career instructors may be in a period where practices are still forming and therefore more open to intentional shaping. Over time, particularly when experimentation occurs without sustained feedback, instructional routines can become entrenched. This raises questions about when and how departments intervene to support reflective development. If teaching practices solidify through repetition, then structured mentorship and community engagement early in a faculty member's career may be especially important.

More broadly, these findings complicate the familiar claim that faculty simply teach the way they were taught. Prior experiences matter, but they are refracted through identity, institutional structures, career trajectories, and opportunities for reflection. Making these influences visible may create space for departments to reconsider how graduate mathematics instructors are supported—not only in learning new strategies, but in examining the histories and commitments that shape their practice.

In this study, we examined how middle school mathematics teachers enacted Rough Draft Math [RDM]. Drawing on self-reports from 13 teachers in a larger mixed-methods project, we analyzed teachers' written reflections about how they engaged students in drafting and revising and how successful they perceived these opportunities to be. Teachers' self-reports of their enactments of RDM varied, and we categorized their reports of drafting and revising enactments into explicit and implicit enactments. We also identified differences in teachers' reports of their success of enacting RDM that aligned with whether they reported enacting RDM implicitly or explicitly. A contribution of this study is a framework to characterize RDM enactments in terms of implicit and explicit drafting and revising. Findings also illustrate the value of examining teachers' criteria for success with teaching practices.

Keywords: Instructional Activities and Practices, Middle School Education, Classroom Discourse

Mathematics teachers increasingly try to support students in sharing in-progress ideas, revising their thinking, and taking intellectual risks as they make sense of mathematical concepts. Rough Draft Math (RDM; Jansen et al., 2020) offers one such approach by positioning students' initial ideas as drafts and building classroom structures in which students are expected and supported to revise those drafts over time. Although prior work has documented a variety of RDM-aligned practices and argued that naming and reinforcing these practices can help teachers plan, enact, and reflect on them more deliberately (Jansen et al., 2026), there is a need to develop a framework of how teachers characterize their RDM enactments and how they judge the success of these enactments in their classrooms.

This study addressed that problem by analyzing middle school teachers' self-reports (diary responses) about how they enacted rough drafting and revising over a ten-day period and how successful they perceived those opportunities to be. We focused on (a) how teachers' self-reported RDM practices can be characterized as explicit or implicit enactments and (b) how teachers' success ratings and rationales for success revealed different dimensions of efficacy.

Background

Given that teachers can enact RDM in various ways, it is worthwhile to name teachers' approaches. Specifying and decomposing teaching practices "involves breaking down practices into its constituent parts for the purposes of teaching and learning" (Grossman et al., 2009, p. 2058). Once teaching practices have been named and labeled as discrete instructional moves, teachers can practice them and improve them in a more targeted manner (Grossman, 2011) due to having access to a specific technical language for teaching (Grossman et al., 2009).

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Listening to teachers' voices about their practices provides insights about what teachers can see themselves enacting in their contexts. RDM has been developed previously through listening to teachers' voices (e.g., Jansen et al., 2016) because research has a greater impact on practice when teachers play a purposeful role in the research process (Cai et al., 2017). We amplify teachers' voices to offer resonance and credibility to our investigation, which are criteria for quality in qualitative research (Tracy, 2010).

Explicit and Implicit Approaches to Rough Draft Math

Rough Draft Math takes place when teaching has been intentionally planned and enacted to provide students with opportunities to draft and revise to make sense of mathematics. Teaching with intention involves planning and making instructional decisions that are purposeful and deliberate on the part of the teacher (Fisher et al., 2016). However, intentionality behind teaching practices may be communicated to students more and less explicitly.

Some teaching practices intended to support students engaging in learning could be enacted in ways that are "useful but subtle" (Watagodakumbura, 2013, p. 303). One example is allocating time for what teachers value (e.g., time for students to engage in well-thought-out reasoning rather than recalling). Students may be aware of the literal event (e.g., more time) but they might be less aware of benefits that they could experience (e.g., greater opportunities to develop their reasoning) if teachers do not explain potential benefits to students.

In our research group's prior work (Jansen et al., 2026), we found that teachers reported that they enacted RDM with more or less explicitly communicated opportunities to revise. We interpreted explicit revising opportunities as events when students were all asked to write more than one attempt of their thinking or solution through a structured activity. Explicit revising often took place on a written document where students had specific sections to write a first draft and a revised draft. An example would be the Math Language Routine (Zwiers et al., 2017), Stronger and Clearer Each Time; students write a first attempt, discuss those first attempts with peers, and then write a second attempt. We interpreted implicit revising opportunities as instances when it was possible for a student to revise, but not every student was asked to do so. An example would be having students work in groups, but not asking students to document multiple attempts, as students could potentially revise after hearing a peer's point of view, but they were not directly asked to do so.

Teachers' Self-reports of Successful Teaching

Teachers' reports about their teaching can reveal their sense of teaching efficacy, which is beliefs about their capabilities as teachers (Tschannen-Moran, et al., 1998). According to Wheatley (2005), there are multiple dimensions for teachers to use to judge the success of their teaching: (a) teachers' perception of their ability to enact a practice (agent-means efficacy), (b) teachers' perception of whether an enactment of teaching can generate positive student outcomes (means-ends efficacy), and (c) teachers' perception of their ability to generate positive student outcomes (agent-ends efficacy). When understanding teachers' self-reports of their success with teaching, it is worth investigating which dimensions teachers report.

Data and Methods

Procedures

We collected data within a larger mixed-methods study exploring the nature of middle school mathematics teachers' rough drafting and revising practices. We instructed teachers to select a single class period from among their rotating mathematics classes to focus on. Teachers completed self-reports in the form of diary reflection activities about their typical rough drafting and revising practices in their selected class period.

Participants

Thirteen secondary mathematics teachers participated during the 2025/2026 academic year. Teachers were from two U.S. states, one in the Mid-Atlantic and one in the Pacific Northwest. The majority of teachers were Female (77%; 10 teachers), and White (77%; 10 teachers), 8% were Asian, Latino/a, and biracial, respectively (1 teacher each). Teachers ranged in years of experience as a teacher of record from 4 to 28 years. 46% taught 6th grade (6 teachers), 15% taught 7th grade (2 teachers) and 38% taught 8th grade (5 teachers).

Measures

All teachers completed diary entries during the second half of September. The goal of the teacher diary activity was to capture a general picture of the rough drafting and revising practices that are part of each teachers' daily mathematics instruction. Teachers responded to a fillable Google form which included 9 survey questions and 15 open-ended text entry questions. We asked teachers to reflect on the past two weeks (10 school days) of instruction in their focal class period and to then report the topics they taught, whether and how these topics aligned with rough drafting and revising, their enactments of rough drafting and revising practices while teaching including whether, when, how, in which contexts and to what extent they enacted these practices, and their perceptions of the success of these enactments.

For this study, we investigated teachers' open-ended text-entry responses. Open-ended questions were typically presented after teachers were asked to report on specific practices via list-selection items. For example, one list selection item asked teachers: "Over the 10 school days, during the following activities/lesson phases, did you enact revising? Select all that apply." We provided choices including "launching a lesson," "while discussing publicly displayed student work," or "at the conclusion of the lesson," among others. The open-ended item to follow was: "Look at the activities/lesson phases that you selected above. In a few sentences, tell us more about the extent to which you enact revising in each of these lesson phases."

Two members of our team assessed teachers' text entry responses according to an investigator-developed qualitative criteria for coding, using and open-ended, emergent process. We engaged in what Saldaña (2013) called "eclectic" coding, which was a back-and-forth process between identifying possible codes from the data and testing the codes on additional data points, refining as needed.

We categorized each enactment quote, for drafting or revising, as either explicit or implicit. *Explicit enactments* were described as structured activities in which all students were expected to participate. *Implicit enactments* were instances when teachers used drafting and revising language to build an environment conducive to drafting and revising or to encourage a discretionary drafting/revising activity that was not a required component of the lesson. One team member coded quotes describing drafting enactments and one coded quotes describing revising enactments. We then sub-categorized based on the function of each enactment (e.g. "activating prior knowledge" or "initial solving attempt.")

For the second research question, two members analyzed open-ended responses in which teachers reported how successful their drafting and revising opportunities were in helping students refine or reframe their thinking. We coded these responses for the criteria teachers wrote to determine success of their enactments. Teacher success ratings (very/mostly successful vs. somewhat successful) were then interpreted in relation to these coded indicators of student thinking.

Findings

Research Question 1: How can middle school mathematics teachers' self-reported enactments of drafting and revising be characterized as implicit or explicit?

Explicit Enactments of Drafting

Teachers reported multiple ways of explicitly engaging students in drafting. For instance, teachers shared that they asked students to write down initial thoughts individually before working with peers or to draft in groups before sharing at a larger level. When describing explicit drafting in their classrooms, teachers focused on different functions, such as: (a) eliciting students' first attempts, (b) activating prior knowledge, and (c) generating predictions.

Eliciting first attempts. Teachers reported using explicit drafting routines for students to start a solution process for a new problem or topic. Ms. Sponaugle explained the start of her routine: "Typically I use rough draft math the most when introducing a new topic … The first step introduces the problem and students are asked to provide a rough draft on how to solve it." For her lesson, she described: "RDM is completed with practice problems at whiteboards throughout the lesson. Students are typically given a higher-order thinking problem and asked to present a draft; whole group/small group discussion occurs before editing and finalizing their solution." Throughout their lessons, teachers used drafting as an entry point into problem-solving.

Activating prior knowledge. Teachers also used drafting to activate students' prior knowledge about new concepts. Ms. Brennan shared a specific example: "I utilize rough draft math at the beginning of lessons to see what students already know about the concept of ratios and unit rate… I had students write down what they thought a double number line was and what it could be used for." She then noted: "By having this knowledge to pull from, students were able to come up with a rough draft initial idea as to what unit rate may be." Ms. Brennan's example showed how a teacher could use an explicit drafting task, in this case, wondering about a double number line, to prompt students to share their existing knowledge of a topic to build on later.

Generating predictions. Teachers also reported using drafting to generate students' predictions about new concepts or vocabulary. Ms. Dougherty wrote: "We often set up our lesson with some predictions or ideas about a concept." Ms. Brennan described her process of drafting with whiteboards: "I have students write out on their whiteboards what they think the [vocabulary] term means and how it relates to the task." Drafting in this way required students to make predictions about concepts and connect those ideas to the lesson. This was an explicit drafting routine because students were given a specific prompt to draft with a structured goal.

Implicit Enactments of Drafting

Implicit drafting often occurred when students were working in groups or during whole-class discussion. These practices were implicit because they were not structured or planned drafting events. Implicit practices, like explicit practices, also seemed to have specific functions, such as (a) modeling drafting and (b) creating a culture of drafting in the classroom.

Modeling drafting. During a lesson, students can learn what it means to draft from peers or their teachers. Ms. Brown wrote: "In the whole group, the students who are comfortable can model what it looks like to rough draft ideas and take risks. In the small group settings, the quieter students feel more comfortable engaging in these tasks." Ms. Alderman explained that teachers can also model drafting: "During lessons in seminar space, I modeled thinking aloud through rough drafting." Teachers can use modeling, either by students or themselves, to demonstrate how to draft. These moments of modeling were implicit enactments because they

provide a space for students to understand the drafting process without being expected to do so, as drafting is not a required component of the lesson.

Creating a culture of drafting. Implicit drafting practices can foster an environment where drafting is encouraged in various stages of a lesson. Ms. Alderman shared: "Most of our time spent rough drafting happens in the heart of the lesson as students are persevering through problems." Mr. Young builds a culture of drafting in his classroom, addressing an "I don't know" by encouraging drafting: "My response of their sharing of 'I don't know' to a question has often been, 'Thank you… can we think this through as a class? We're rough drafting this…'" Although these might not have been planned drafting events, students were working in the spirit of drafting as they solved problems in class and were encouraged by their teacher to engage in drafting to problem solve, whether planned or spontaneously. Given that not all students were expected to draft in these discussions, drafting was an implicit practice.

Explicit Revising

Teachers also reported multiple ways of explicitly promoting revising, often at the end of the lesson or after a collaborative activity. If teachers had students discuss their drafts in groups (and/or in whole class discussions), some of these teachers explicitly asked their students to document revisions to their thinking that were informed by these interactions. Another explicit revising opportunity teachers reported was allowing students to revise tests or quizzes.

Revising as a reflective lesson closure. Some teachers incorporated revising by closing their lessons and asking students to write down how their thinking had changed. For instance, Mr. Young stated: "Students have also been asked to reflect at the end of a lesson with 'At first I thought ___, now I think ____.'" Similarly, Ms. Brennan described how revising occurs during and at the end of her lessons:

> As the lesson progresses, I have students go back to their definitions and add notes or diagrams to what they already had written. I also have students who were completely off describe using sentence frames, such as 'at the beginning of the lesson I thought… now I think.… My thinking changed because…' After student discussion at the whiteboards, I then allow students ample time to revise their thinking a final time during their cool down/independent work time.

Revising after collaboration. Teachers incorporated explicit revising through peer collaboration. Teachers expected students to revise their individual work after talking with partners. For example, Ms. Shisler noted: "In Sub-Unit 2, students worked on scale drawings. Once they talked with partners and also saw student work, students revised their thinking and drawings." Another teacher, Mr. Young, described revision occurring after discussion using a different color to indicate changes to students' prior drafts:

> During partner talk, partner work time, and in whole group plenary discussion I will ask students to think about whether their thinking is the same or different. When applicable, I will then encourage them to look specifically at what led to them having different answers to then decide what answer makes most sense. I encourage them to *not* erase, use a different color pencil for revisions.

If a teacher expected all students to write down how their thinking changed after collaborating, the teacher enacted revising explicitly.

Revising tests or quizzes. Lastly, teachers provided explicit revising opportunities by allowing students to revise tests or quizzes. Mr. Jenkins stated: "Students turn their quizzes/tests in and get them returned highlighted with no grade. [They can] make corrections and elaborate

on what was done incorrectly." Another teacher, Dr. Green, described: "To earn back points, they must retake the assessment, so the revisions will help them know what to review." If teachers invited every student to complete assessment revisions, this was explicit revising.

Implicit Revising

Teacher reports of students potentially revising, but having no structured activity asking them to do so, indicated implicit revising. Teachers wrote that they suggested revision opportunities to students, but these did not describe events when all students were expected to revise. Descriptions of implicit revising sounded like reminders from the teacher, perhaps in an effort to create a classroom culture of revising, in contrast to revising events or activities.

Teachers' examples illustrated this implicit positioning of revising as discretionary, rather than event-based. Ms. Brennan described: "students are reminded throughout their small group instruction at their whiteboards that they can add or change ideas to their initial thoughts at their own discretion," without identifying a specific moment when revision was expected to occur. Likewise, Dr. Green emphasized encouraging clarifying questions and invoking students' "right to revise their thinking" during small group work: "I introduced students to Torres' Rights of the Learner at the beginning of the year and I try to use the phrase 'right to revise your thinking' either by noting when students are using that right or when students can use that right." Similarly, Ms. Dougherty noted that revising could occur at any point, depending on the student: "Some students can revise their thinking as we talk in whole group, while some need more 1:1 support and instruction to really understand enough to revise." These examples demonstrate implicit revising enactments, in which teachers positioned revising as an available and valued practice but left its enactment largely unstructured.

Teachers' Perceived Success

Research Question 2: How do teachers' reported success levels and rationales differ between implicit and explicit enactments of rough drafting and revising? We observed that some teachers' success ratings for enacting drafting and revising [RDM] appeared to align with their observations of changes in students' thinking. Teachers who reported greater success with enacting RDM (very or mostly successful) and reported explicit enactments of RDM also reported criteria for success in terms of students' thinking. Teachers who reported less success or implicit enactments did not use these criteria to determine success. We interpreted teachers' reports of success through Wheatley's (2005) lenses of agent-means, means-ends.

Explicit Enactment and Very/Mostly Successful

Teachers who reported enacting RDM explicitly and rated their enactment as very or mostly successful described success in terms of shifts in students' mathematical thinking. BJ reported that rough drafting "got students thinking, they produced quality work, and it has them looking at math in a totally different way." Ms. Shisler, similarly, grounded her 'very successful' rating in how students changed their ideas: "When I move them to Mode 2, I hear a lot of agreeing and disagreeing and see students revise their original thinking. During Mode 3, when we share out as a class, students either add on to their original rough draft thoughts and answers, or they revise their thinking altogether and change their answers or drawings." For these teachers, success aligned with how RDM (means) led to changes in students' thinking (ends).

Explicit but Somewhat Successful

In contrast, teachers who reported enacting RDM explicitly but rated their enactment as only somewhat successful justified their ratings by pointing to limits in student engagement (ends) or doubts about their own enactment (agent). For example, Ms. Sponaugle wrote: "students are used to copying notes and were first confused as to what to write or how to go about each revision.

When working in small groups, not all students were actively engaged. With the introduction of a lesson, time to complete all steps was challenging." Her 'somewhat successful' rating may reflect an incomplete drafting-revising cycle and uneven participation, which did not lead to refined thinking across the class. Mr. Young also implemented explicit drafting routines; however, he wrote: "I'm not sure I am doing what I am supposed to be doing… there's so much I want to do with them that it has been hard to prioritize a sequence that helps build their capabilities (while moving along with what the curriculum requires)." Here, the teacher's rating may be tied to his uncertainty about his enactment (agent) of explicit drafting and revising routines (means). He expressed uncertainty about whether he implemented the approach correctly and described struggling to prioritize instructional steps that both support students' development and meet curricular demands.

Implicit Enactments and Success Criteria Reported

Teachers who reported implicit enactments, regardless of their reported level of success with RDM, usually described success in terms of student engagement or classroom culture. Ms. Miller, who rated her (implicit) enactment as very successful, wrote: "We are in a constant state of rough drafting and revising. 'I'm not sure but…' is used all day long. Students are encouraged to think out loud and revise whenever they need to do so," and concluded that "rough draft & revision is part of our classroom culture. We are 2 months in, and students have taken ownership of the process." Her evidence for success centered on students' willingness to participate and take ownership, not on descriptions of changes in students' thinking. This was a means-ends reflection on teaching effectiveness. Her ends outcome (e.g., engagement) differed from the means-ends reflections among teachers reported explicit, strongly successful enactments. Mr. Pryzbylewski rated his implicit enactment as somewhat successful, and similarly highlighted: "I have not succeeded much with formal revising… we don't have a routine or system where we intentionally plan to revise something." This was an agent-means reflection because he reflected on his own success with enacting RDM. He added: "I think the spirit of rough draft thinking is in the classroom." This part of his rationale for success emphasized using RDM to guide his instruction (means) and cultivating the "spirit" of rough draft thinking (ends of classroom culture) rather than changes in students' thinking (ends of students' thinking).

Discussion

We determined that teachers reported enacting RDM with explicit and implicit drafting and revising practices. We also determined that teachers reported a range of success levels, but the teachers who reported strong success and explicit RDM enactments also reported changes in their students' thinking. Our findings indicate that teachers can enact RDM in their classrooms in different ways with a range of functions, and that there were different ways that RDM added value to their teaching. These benefits included changes in students' thinking over time and changes in students' engagement or the culture of the classroom.

Teachers' Explicit and Implicit Enactments of Drafting and Revising

Teachers shared that they enacted drafting and revising in a variety of ways, as found previously (Jansen et al., 2026). Some reported explicit RDM activities and others reported more implicit RDM enactments. Teachers explained that drafting can create a basis for later revisions, either by revising individually or in groups. Implicit RDM practices can also be valuable for sustaining a classroom culture of ongoing learning. When the language and spirit of RDM are present, students may already be accustomed to the ideas of drafting and revising, even without structured activities. This study extends this research team's previous work (Jansen et al., 2026)

by adding more clarity to definitions for explicit and implicit RDM enactments and providing additional examples of explicit and implicit RDM enactments.

Teachers' Perceptions of Successful Enactments

Our analysis revealed differences in teachers' criteria for success, and these criteria varied both in terms of teachers' perceptions of success and whether they reported enacting RDM implicitly or explicitly. We interpreted that teachers drew on different perspectives on teaching efficacy (Wheatley, 2005): (a) agent-means efficacy [their (agent) perceived ability to enact RDM (means)], (b) means-ends efficacy [whether RDM (means) generated positive student outcomes (ends), such as revisions to students' thinking or improvements to students' engagement]. Teachers who reported implicit enactments of RDM or teachers who reported less success with RDM did not refer to students' thinking as evidence of success with RDM. Our analysis extends Wheatley's (2005) research by showing how RDM enactment type and perceived levels of success with RDM may align with different efficacy judgments.

Limitations and Future Research

We acknowledge that this study is limited due to a relatively small sample size. Additionally, with written reflections, we cannot probe for future elaborations as we could during an interview. However, the value of this analysis is that we were able to identify explicit and implicit RDM practices, which could be studied in other classrooms. These practices are also worth naming so teachers could adopt them into their own practice (Grossman et al., 2009).

Future research could investigate how teachers' self-reports of explicit versus implicit practices align with researchers' observations of their teaching. Teachers might not report components of their teaching practice that a researcher could see as productive in a video-recorded observation. Finally, we studied only middle school teachers at a single point in time. Further research could explore self-reports of teachers at other grade bands and over time.

Implications for Teaching Practice and Teacher Education

If teachers develop an awareness of a variety of explicit and implicit drafting and revising practices, they could reflect upon enactments to try in their own classrooms. Drafting and revising can serve multiple functions in a classroom. Some teachers might choose to enter into enacting RDM implicitly by using drafting and revising language to create a culture of drafting and revising in their classrooms. Alternatively, teachers may first try explicit enactments to help students understand the value and purpose of RDM. Professional development for teachers could introduce teachers to various RDM enactment approaches and support teachers with recognizing criteria that they use to determine success. Teachers could consider how to improve their practice and see strengths in their teaching that they can build upon through identifying their RDM enactments and considering a variety of dimensions for interpreting success of their teaching.

Conclusions

Our study of self-reports of teaching showed that teachers enacted RDM practices in their classrooms in multiple ways and with multiple functions. Teachers enacted drafting and revising explicitly (through specific activities) and fostered a culture of drafting and revising (through implicit practices). Secondly, teachers reported varying levels of success with enacting RDM, but those who reported more success and explicit RDM enactments also reported changes in their students' thinking. We continue to stress that teachers' voices are a valuable resource for understanding their practices in the classroom, and we also advocate that researchers benefit from trusting teachers' self-reports as evidence of their classroom practices.

ECOLOGICAL FACTORS INFLUENCING MATHEMATICS TEACHERS' INSTRUCTIONAL DECISION-MAKING: A CROSS-CASE SYNTHESIS

Camille Lund
Weber State University
camillelund@weber.edu

In this qualitative multiple-case study framed by Bronfenbrenner's ecological systems theory, the author conducted semi-structured interviews with three elementary teachers in districts across northern Utah. These interviews utilized the novel Ecological Factors Map to explore how teachers described the interplay of factors within their ecological systems and the influence of these factors on their implementation of mathematical student discourse. After developing within-case themes through a thematic analysis, the author performed a cross-case synthesis to identify themes spanning the three cases. These cross-case findings highlight the complexity of teacher decision-making and show that various factors within each participant's environment interact to affect their decision-making. This paper incorporates extant literature into a discussion of the cross-case findings and provides recommendations for educational leaders.

Keywords: Instructional Activities and Practices, Classroom Discourse, Elementary School Education

Introduction

As educational leaders work to promote stronger mathematics academic gains for students, the instruction that takes place in the classroom does not always align with what is considered best practice (Remillard, 2005). Though mathematics education research is robust, there remains a gap between research and the practices that take place in real classrooms (Silver & Lunsford, 2017). Because the instructional decision-making of mathematics educators is complex and affected by various factors (e.g., Bartell, 2011; Conner & Singletary, 2021; Herbel-Eisenmann, 2006; Ruef, 2021; Schifter, 1995), there is a need for research that examines the interplay of factors that influence teachers' instructional decisions in the mathematics classroom. This exploratory study used ecological systems theory (Bronfenbrenner, 1974, 1977) to explore how teachers described their decision-making related to one extensively researched teaching strategy—mathematical student discourse (MSD). Here, MSD refers to the opportunities for students to engage in mathematical discussions in whole-group, small-group, or peer-to-peer settings (Chapin et al., 2009). In this study, participating teachers used MSD to refer to many different forms of mathematical discourse, including whole-group discussions, brief opportunities for students to share an idea with another student, choral or individual responses to questions posed by the teacher, and partner work. The purpose of this study was to explore factors influencing teacher decision-making for instruction involving MSD (as well as mathematics instruction more generally) in order to better understand the support teachers need both individually and collectively to provide rigorous mathematics instruction to all students.

Theoretical Perspective

Ecological Systems Theory

Ecological systems theory, developed by Urie Bronfenbrenner (1974, 1977), suggests that humans' development is impacted by the interactions of aspects of their complex environments, or ecosystems. Bronfenbrenner (1977) conceptualized four systems that make up an individual's environment and influence the individual's development: (1) the microsystem—the

environmental settings and elements with which the developing individual directly interacts, (2) the mesosystem—the interrelations between the microsystem elements, (3) the exosystem—interrelations between social structures that influence the individual's setting, and (4) the macrosystem—the overarching culture and patterns encompassing the developing individual's world.

Though ecological systems theory is a theory of human development most often used in social work, educational studies that have used this theory as a framework (Buchanan, 2020; Falloon et al., 2022; Smith et al., 2017) demonstrate that the highly complex and social field of education can also benefit from such a holistic examination. In this study, the theory provided a meaningful lens through which to view the experiences of teachers and the interplay of ecological factors that affect their decision-making for mathematics instruction, particularly related to the facilitation of MSD.

Figure 1 illustrates the conceptual framework for this study, framed with an ecological systems perspective. At the center of the framework are the teacher and components of the teacher (Remillard, 2005). An arrow connects the teacher to the teacher's decisions for MSD, representing the effect that the teacher and the components of the teacher have on their implementation of MSD. Factors shown to influence teacher decision-making sit within the teacher's ecological systems. Bidirectional arrows show the influence that these factors may have on each other, and on the teacher and the teacher's decision-making.

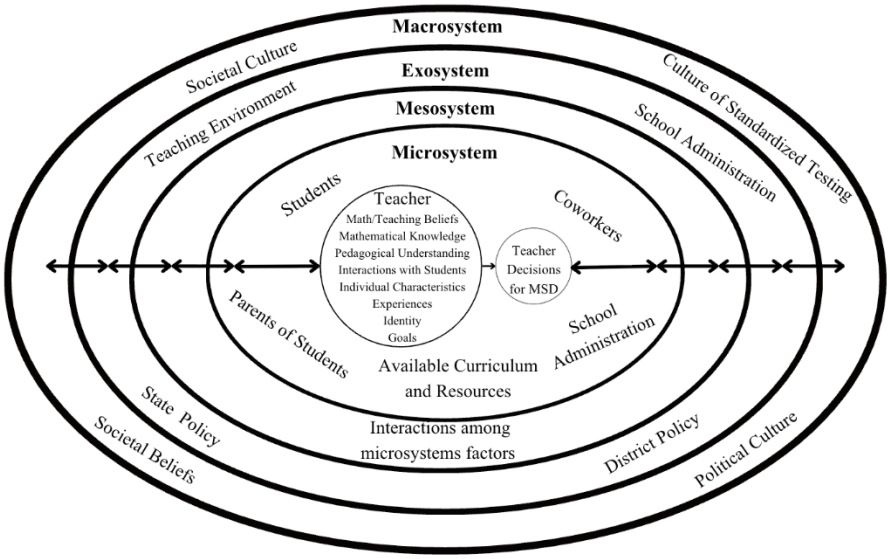

Figure 1: Conceptual Framework

Method

I conducted a multiple-case study (Yin, 2014) of three elementary teachers who teach mathematics in separate districts across northern Utah. I conducted teacher interviews, which were audio recorded and transcribed, with each participant utilizing the novel Ecological Factors Map (EFM, see Figure 2). I created the EFM based on the ecological systems theory (Bronfenbrenner, 1974, 1977) and the research literature describing factors that influence teacher decision-making in mathematics classrooms (Ayalon & Even, 2016; Bronfenbrenner, 1974, 1977; Davis et al., 2020; Herbel-Eisenmann et al., 2006; Smith et al., 2017; Remillard, 2005).

The EFM was displayed on a single 8-inch by 11-inch document and included several factors from each ecological system shown in the conceptual framework (see Figure 1).

The participants were three generalist elementary teachers referred to by the pseudonyms Taylor, Sarah, and Carmen. All participants had taught elementary mathematics in a general education setting for at least three years. Taylor was a white male fifth-grade teacher; Sarah and Carmen were both white, female first-grade teachers. Carmen taught in a dual-language immersion (DLI) classroom where she and her students spoke in Spanish.

In the teacher interviews, I asked the participants to describe the MSD that takes place in their classroom. I then asked the teachers to take a careful look at the concepts listed on the EFM and asked them to create a visual on the EFM that illustrated how certain factors influence how they implement student talk in their classrooms, either positively or negatively. I asked the participants to talk about their actions as they performed them. This use of the EFM allowed the participants to discuss complex influences of various interconnected factors on their decision-making and teaching experiences. The completed EFMs from each interview are displayed in Figure 2.

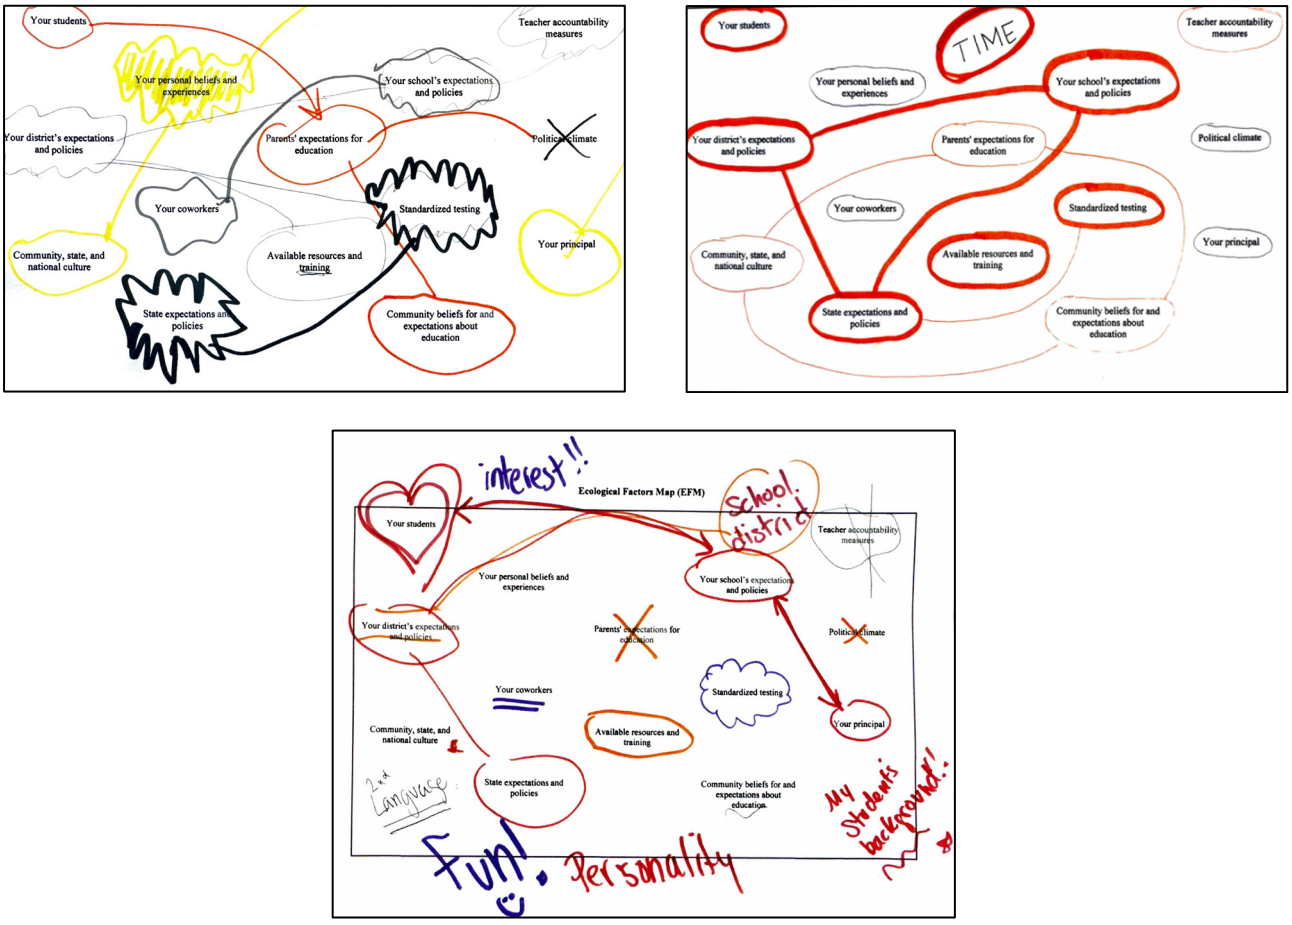

Figure 2: EFM Visuals Created by Taylor (top left), Sarah (top right) and Carmen (bottom)

While decision-making for MSD served as a focal point and the primary interest of this study, it was anticipated that the teachers may discuss decision-making for mathematics

instruction generally. This proved to be the case, with the teachers occasionally discussing ideas and experiences related to mathematics instruction broadly. Such ideas were seen as important elements of the teachers' complex experiences as educators and were included in the analysis.

Data Analysis

I conducted a thematic analysis (Nowell et al., 2017; Riger & Sigurvinsdottir, 2016) of the data sources described in the previous section. This process involved becoming familiar with the data in the form of audio recordings, transcripts, and EFM visuals; taking analytic notes; generating initial codes in the transcripts using MAXQDA; searching for themes; iteratively reviewing and altering themes that were eventually defined and reported; and performing member checks with each participant (Nowell et al., 2017). The unit of analysis was a concept or idea shared by the participant, whether it be a sentence or a paragraph from the transcripts.

I first conducted three within-case analyses of the data from each teacher's interview and EFM. I triangulated the data for these analyses with administrator interviews and classroom observations, which are not directly discussed in this report. After completing the within-case analyses, I conducted a cross-case synthesis (Yin, 2014) by searching for patterns across the within-case themes (see Figure 3). The development of cross-case themes emerged from iterative reviews and alterations as I returned to raw data and took detailed analytic notes. This paper includes a discussion of the cross-case synthesis connections to relevant extant literature.

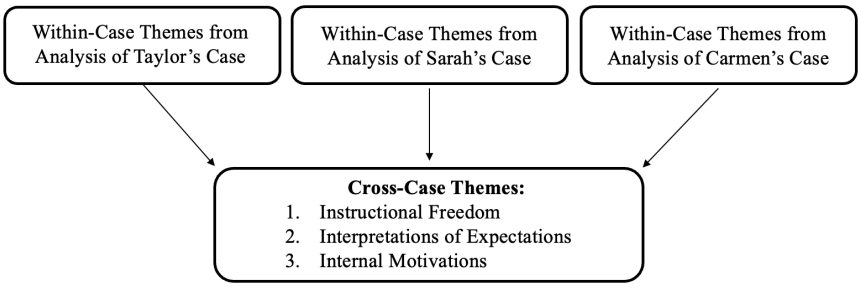

Figure 3: Analysis Process for the Development of Cross-Case Themes

Findings and Connections to Literature

Each teacher expressed unique ideas throughout the interview as they created their visuals on the EFM. While full reports of each case are reported elsewhere (Lund, 2026), this research report focuses on the cross-case themes synthesized from the findings of all three cases. To provide context for these cross-case themes, a brief overview of the within-case findings is reported here.

Taylor discussed conflicts between his personal views about mathematics instruction—which centered around problem-solving and real-world application with natural connections to MSD—and expectations from his students' parents, his district, and the state. He shared a perception of "foggy" expectations from his district—especially related to standardized testing—and his negative feelings toward state policy and standardized testing as "enemies to education" that, in his mind, are both unhelpful and discouraging. Sarah described her focus on student needs through instructional strategies such as MSD and a sense of instructional freedom that was largely based on a personal sense of confidence and the ability to view expectations from educational bodies as "guidelines," creating a flexible framework for her instructional decisions. Carmen also described a focus on her students, including their needs, interests, backgrounds, and

sense of fun. She shared ways that she chooses to use MSD to meet student needs and described expectations from her school and district that aligned with this teaching style.

Cross-Case Themes

This section includes the three cross-case themes discovered from the cross-case analysis. Each theme is discussed in connection to extant literature relevant to the findings.

Cross-Case Theme 1: Instructional freedom. The three teachers shared experiences connected to instructional freedom that influenced their instructional decision-making. Sarah and Carmen experienced strong instructional freedom within their schools and districts. They discussed ways that they use this freedom to prioritize MSD, flexible problem-solving, and conceptual understanding to meet their students' academic and personal needs and to align instruction with their own personalities and values. Sarah and Carmen seemed to enjoy this sense of freedom and did not express a desire for more guidance. Carmen noted how working in a DLI classroom afforded her more instructional freedom than her English-teaching counterparts:

> We have the same curriculum, but English teachers don't have that freedom like [what] we Spanish or Portuguese teachers, we have. And English teachers, they have, like, every single time measure, and they have a routine to do it, and they give them the routine, and even the words that they have to say. But [if] we want to do routines, or we want to do something, we have to create our own.

Though Taylor did not specifically discuss the degree of instructional freedom allowed him, he shared pressures to follow strict, testing-focused guidelines promoted by his district and school. While he expressed a desire to teach more in accordance with his personal beliefs and experiences through application-based pedagogy and real-world problem-solving, he expressed frustration at the misalignment between this personal compass and the realities of standardized testing and state expectations. However, rather than express a desire for more instructional freedom, Taylor shared his search for clarity among foggy expectations. Feeling that he does not naturally know what his students need, he described his desire for a clear outline of what to teach and how. "I'm not one of those teachers that just knows my kids and knows what they need," he shared, "… so I want to get [clear guidance], and it's not there."

These nuanced experiences with instructional freedom are supported by literature on teacher autonomy (Cribb & Gerwirtz, 2007; Jerrim et al., 2023; Narayanan et al., 2024). Teacher autonomy is complex and not experienced the same by all teachers. In this study, Sarah and Carmen seem to benefit from feelings of instructional freedom and autonomy. Taylor does not experience the same sense of autonomy, but it is unclear if he wants it. Though he wishes he could make different instructional decisions aligned with his personal teaching values, he desires clearer expectations to guide his instruction.

Cross-case Theme 2: Interpretations of expectations. Each teacher shared a unique view of expectations from their school, district, and state. Sarah referred to state expectations as "guidelines" and explained how her sense of confidence allows her to implement MSD without excessive supervision. She stated that she would implement MSD "no matter what" even in the face of conflicting expectations because of how important MSD is for young students growing socially and academically. She said:

> I take the district expectations, the state expectations, the school's expectations, the standardized testing, the resources … I take all of that, but … I don't let it like affect my decision-making process. I trust myself enough to know that the things that I'm doing are

> within [these] expectations. But it is essentially what's best for my students, and at the end of the day for me, that's what's most important.

Carmen expressed similar sentiments, describing the freedom and support she is allowed by her principal and district. Carmen described a lack of tension between her desired teaching style—which involves lots of movement and student talk—and expectations from her school and district. She feels encouraged to incorporate MSD into her classroom to support her students who are growing socially, academically, and linguistically, and she adheres to standards while modifying her curriculum as she and her team teacher see fit.

Taylor described expectations from his school, district, and state as more strict than the other teachers did. As mentioned earlier, he described feelings of pressure to adhere to testing expectations and a desire for more clarity about these expectations. Speaking of standardized testing and state expectations and policies, he said:

> [They] are there to make life more difficult, teaching less effective, and to basically rub our noses in us not doing good enough … Very negative connotations in my mind from those two. I feel like state expectations and policies and standardized testing is the enemy of education.

The different interpretations of expectations among the teachers may be connected to standardized testing expectations. Taylor, as a fifth-grade teacher, must prepare his students for end-of-year state-mandated standardized tests in mathematics, writing, reading, and science (Utah State Board of Education, 2025). As first-grade teachers, Sarah and Carmen do not administer these high-stakes standardized tests. Research supports the idea that testing pressures have a strong influence on teacher experiences and instructional decision-making (Moon et al., 2007; Ramsay-Jordan, 2020; Stevens, 2023; Youn, 2018). Standardized testing can cause feelings of limitation in instructional practices, a narrowing of the curriculum, and a dependency on district-provided resources (Stevens, 2023). High testing expectations can also lead to teacher frustration, a lack of instructional flexibility, limited demand for rigorous and cognitively demanding instruction, difficulty implementing culturally responsive pedagogy, and a decrease in teachers' feeling of empowerment (Moon et al., 2007; Ramsay-Jordan, 2020; Youn, 2018).

While Sarah and Carmen seemed confident in their understanding of expectations overall, Taylor repeatedly described expectations and policies as "foggy." His district provides many resources for mathematics instruction, but he is often unsure of how to use them to meet strict expectations. This interpretation aligns with Allen's (2023) findings from a study on teachers' sensemaking of expectations regarding a newly mandated curriculum, where the author differentiated between *ambiguity* and *uncertainty*. (i.e. "ambiguity" as confusion in the face of too many possible interpretations and "uncertainty" as confusion in the face of too little information) to understand the teachers' experiences. Based on the interview data, Taylor may be experiencing uncertainty because of too little information provided about how to utilize the testing-focused resources he is expected to use. Or perhaps his experience is better described as ambiguity: he has access to a lot of resources and curricular materials with too many interpretations for their use. Unfortunately, Taylor has not found ways to uphold the spirit of his school's, district's, and state's expectations without being weighed down by specifics, as it seems Sarah and Carmen have. As a result, it seems that Taylor feels less confident implementing MSD through real-world application and problem-solving tasks like he wishes he could, instead focusing on improving his students' test scores and grades and meeting other school and district expectations.

Cross-case Theme 3: Internal motivations. The teachers' internal motivations, sitting within themselves at the center of their ecological systems, strongly influenced their decision-making. Sarah and Carmen stated that their students most strongly influenced their decision-making, even considering school and district expectations, state policy, and parent expectations. Taylor, in contrast, described his personal beliefs and experiences with mathematics—focused on real-world application—as the factor that allows him to do his best teaching. He expressed a desire to better align his teaching with this internal motivation as a result of our interview and mused that focusing more on understanding his students as individuals would help him look past oppressive testing policies and focus on his internal motivations.

These findings reflect a description of the microsystem as including the individual's personality, temperament, and beliefs (Crawford, 2020). From an ecological perspective, these findings prompt questions about how certain internal motivations situated within an individual's microsystem may interact with other factors within the individual's mesosystem, exosystem, and macrosystem. For example, Sarah and Carmen engage in daily interactions—or reciprocal proximal processes (Bronfenbrenner & Morris, 1998)—with their students, encouraging them to modify their instruction and curriculum to meet their students' needs even if it means pushing back on expectations from their students' parents, their school, their district, or their state. It is possible that, because these teachers are oriented toward meeting their students' needs and because they work in a low-stakes testing environment with administrators who do not discourage them from these modifications, this kind of reconciliation between internal motivation and external expectation is easier achieved than it is for Taylor. Taylor, who is more oriented toward his personal beliefs and experiences with mathematics, works within a high-pressure testing environment and lacks clarity in testing-focused expectations. In this context, he may find it difficult to push back on expectations and focus his instruction on real-world application and other instructional activities more aligned with his internal motivations.

Implications for Educational Leaders

A goal for exploring teacher decision-making through ecological systems theory was to inform educational leaders how to support teachers both individually and collectively so as to contribute to the closing of the research-practice gap for rigorous mathematics instruction. The following recommendations based on the findings of this study offer a clearer vision of what educational leaders can do—in northern Utah and beyond—to support this cause.

Recommendations for District Leaders and Principals

The following are three recommendations for district leaders and principals based on the findings of this study: (1) provide clarity, (2), balance instructional freedom and professional learning, and (3) recognize differing internal motivations among teachers.

1) Providing clarity. District leaders and principals should strive to provide clarity to their teachers about their expectations for mathematics instruction. This includes clarifying logistical expectations for standardized testing preparation. They should articulate the purpose and limitations of these assessments for accountability and instructional improvement. District leaders in particular should clarify the importance of high-impact instructional strategies like MSD, even considering testing pressures. They should ensure that teachers and principals understand how standardized testing expectations size up against high-impact instructional strategies that may or may not improve testing outcomes. Providing this clarity to teachers, of course, requires district leaders to first formally determine their position on these matters.

2) Balance instructional freedom and professional learning. To support high-quality mathematics instruction, district leaders and principals should reasonably support instructional

freedom for classroom educators. Instructional freedom should exist alongside quality professional learning that provides educators with the skills and knowledge they need to provide rigorous and equitable instruction (Cribb and Gewirtz, 2007). For example, professional learning on ambitions number talks (Cavanna et al., 2021; Kazemi & Hintz, 2023; Woods & Salem, 2024), open-ended math talks, (Hufferd-Ackles et al., 2004), classroom discussions (Smith & Stein, 2018), and quality questioning, (Hennessy et al., 2023; LaRusso et al., 2024; O'Connor et al., 2017) could support teachers to make their enactment of MSD more rigorous. Furthermore, teacher beliefs about mathematics, about how mathematics should be taught, and about their students influence what MSD looks like in the classroom (Bartell, 2011; Conner & Singletary, 2021; Davis et al., 2020; Kooloos et al., 2022; National Council of Teachers of Mathematics, 2014; Nilsson, 2019; Ruef, 2021; Stockero et al., 2020). Districts and schools should prioritize professional learning that helps teachers develop beliefs that support high levels of student learning, extend noticing skills, encourage self-reflection, and disrupt biased beliefs (Hand, 2012; Mendoza et al., 2023; Ruef, 2021; van Es et al., 2022) so MSD and other high-impact instructional strategies are meaningful and equitable for all students.

3) Recognize differing internal motivations. District leaders and principals should be careful not to assume they know what matters most to teachers or what they find valuable in the teaching profession. Some teachers may feel in tune to their students' needs and may be primarily guided by what they believe is best for their students (like Sarah and Carmen). However, some teachers may be motivated by their personal experiences with mathematics (like Taylor) or something else entirely. These teachers may need more guidance to determine what their students need, to navigate conflicting expectations, or to implement high-impact instructional strategies like MSD.

Recommendations for State Leaders and Policy Makers

Like district leaders and principals, state leaders and policy makers should work to provide clarity in expectations, facilitate instructional freedom and professional learning, and recognize the diverse needs and motivations of teachers. Additionally, state leaders should develop metrics (likely qualitative) to determine how MSD and other rigorous strategies are being utilized in their state. Utah has expectations for the implementation of rigorous instructional strategies (Utah State Board of Education, 2019; Utah State Board of Education, 2022b), which focus in large part on the Standards for Mathematical Practice (Common Core State Standards Initiative [CCSSI], 2010). However, it is not clear if and how state leaders are encouraging districts and schools to use them. Districts may face barriers in promoting these strategies. Maintaining expectations for rigorous instruction alongside expectations for standardized testing results would help close the research-practice gap for strong mathematics instruction and promote student achievement resulting from strong instruction rather than teaching to the test.

Conclusion

This study explored the experiences and instructional decision-making of three elementary teachers through an ecological systems lens. The findings demonstrate the unique experiences of individual teachers within their personal educational environments and provides actions educational leaders can make to better support teacher decision-making for high-impact instructional strategies like MSD. Future research similarly exploring teacher decision-making will help researchers and educational leaders identify and address the complex needs of teachers both individually and collectively as they work together to provide rigorous mathematics instruction to all students.

INTERNAL CONFLICTS IN DESIGNING A MEASURES OF CENTER TASK: A SELF-STUDY

Tracy Proffitt
Virginia Tech
tprof8@vt.edu

This paper explores how five categories of conflict in collaborative task design can be applied in a self-study focused on the design of a measures of center task. The arenas of conflict theory is combined with Hermans' dialogical self theory to extend the construct of conflict from group planning settings to the intrapersonal experience of a teacher-researcher planning independently. Through this extension, the paper demonstrates how the arenas of conflict illuminate key decisions in the design process and can be used to examine how these choices functioned in implementation. Further, the study illustrates the potential for this framework to inform task revision.

Keywords: Preservice Teacher Education, Design Experiments, Data Analysis and Statistics, Instructional Activities and Practices

Selecting and adapting appropriate classroom tasks are key aspects of planning and implementing meaningful mathematics instruction. Sometimes, however, an adequate task that matches students' needs, explores the intended mathematical content, and leverages an engaging context cannot be found, and teachers must take on the role of task designer. In my recent reading about students' initial development of measures of center concepts, I found myself questioning whether the suggested tasks would function as intended, often due to mismatches I perceived between students and the context or between mathematics and the context. In the initial phase of a design-based research project reported here, I designed a measures of center task, implemented it with a small group of pre-service teachers (PSTs), and analyzed the design process through the lens of Barbosa and de Oliveira's (2013) arenas of conflict in task design. Using a self-study approach, the purpose of this project is to illuminate key decisions in the design process, the outcomes of those decisions, and paths for design revision. Specifically, I explore the research question: *What insights about task design are developed through an initial cycle of designing, implementing, analyzing, and revising a cognitively demanding math task focused on measures of center?*

Theoretical Framework

Implementing reasoning and problem-solving tasks is identified as one of the eight mathematics teaching practices in *Principles to Actions* (National Council of Teachers of Mathematics, 2014). A mathematical task can be defined as "a classroom activity, the purpose of which is to focus students' attention on a particular mathematical idea," and tasks are often categorized by the cognitive demand required to complete them (Stein et al., 1996, p. 460). High cognitive demand tasks have been associated with student learning gains (Hiebert & Wearne, 1993; Stein & Lane, 1996), as well as rich classroom discourse (Tekkumru-Kisa et al., 2020), increased student engagement (Hourigan & Leavy, 2023), and positive mathematics dispositions (Sullivan & Mornane, 2014). However, alongside these benefits for students come significant challenges for teachers, including selecting or designing tasks that appropriately align mathematical ideas, student needs, and instructional goals (Crespo & Sinclair, 2008).

Researchers who study children's development of statistical learning offer several recommendations for designing tasks that support students' conceptions of measures of center. First, students benefit from exploring data sets embedded in meaningful contexts and from comparing two or more sets (Konold & Pollatsek, 1999). Comparing data sets provides a legitimate need for students to determine a value that is representative, average, typical, or usual for a set (Mokros & Russell, 1995). Second, researchers suggest delaying the introduction of the arithmetic mean in favor of building an understanding of mode and median first (Mokros & Russell, 1995). When mean, median, and mode are taught simultaneously and algorithmically, students can become convinced that the mean is the only acceptable measure of center (Jacobbe, 2012), losing sight of the usefulness of the other measures (Friel, 1998). Finally, Konold and Pollatsek (1999) hypothesized that repeated measures could be effective contexts for helping students think about measures of center, but they acknowledged that in elementary instruction "repeated measures are rarely used, perhaps because they often lack pizzazz" (p. 18). Designing tasks that attend to these recommendations is a concrete way to connect research and practice.

When designing tasks for classroom use, teachers must weigh mathematical needs against the practical needs of their students and the instructional context (Crespo & Sinclair, 2008). To further illuminate this friction, Barbosa and de Oliveira (2013) identified five arenas of conflict or tension that surface during mathematical task design: the mathematical *context* of the task, the use of *language* to increase or decrease rigor, the *structure* or degree of openness of a task, the *distribution* or the content focus of the task, and the positioning of teachers and students as participating *subjects*. Although the researchers originally observed these conflicts within a collaborative group of academics and teachers (Barbosa & de Oliveira, 2013), I argue that the same tensions operate within myself as I design a mathematical task. Hermans' (1996) dialogical self theory conceptualizes the self as a multiplicity of I-positions that fluctuate across time and space and can be in conversation with each other. Drawing on this theory, I view myself as occupying multiple I-positions at once, each with a unique experience, perspective, and voice. In the design process, *I as a teacher* and *I as a researcher* are in dialogue and negotiating compromises, much like the middle school teachers and academics of Barbosa and de Oliveira's collaborative group (2013). These theoretical lenses provide a structure for analyzing my planning process and the resulting task implementation, and they help surface possible ways in which the measures of center task can be improved in future iterations.

Methods and Data Analysis

Here I report on the first iteration of a design-based research study, an iterative approach that connects theory and practice through the design, implementation, and refinement of educational materials (Bakker & Van Eerde, 2015). The following phases formed the first iteration of the study: designing a high cognitive demand task based on measures of center literature recommendations, implementing the task, soliciting participant feedback, analyzing data, and revising the task. During the design phase, I used generative artificial intelligence (AI) as a thought partner to brainstorm potential contexts and refine task instructions and questioning (Beavers, 2025; Fleischmann, 2026). A thought partner is defined as "another entity (human or AI) that works with an agent to push forward some aspect(s) of thinking" (Collins et al., 2024, p. 1852). The transcript of the AI conversation and the initial draft of the task were collected as data sources. I then facilitated the task with three undergraduate volunteers from an elementary math methods course in which I serve as a graduate teaching assistant. We met for two hours outside of class, and participants received a $10 gift card for their participation. They completed the task collaboratively and provided both written and verbal feedback on the experience. Data sources

from this phase include video and audio recordings of the session, the transcript generated by Otter.ai, participants' work on the task sheets and whiteboards, and verbal reflections recorded after completion of the task.

The collected data were uploaded into ATLAS.ti, a web-based tool for qualitative coding, and I completed an initial cycle of coding to cull episodes that were mathematically or pedagogically relevant to the research question. For example, I removed off-topic conversations that took place while students were stacking and kept instances of comparisons, predictions, and mathematical connections. Within the remaining relevant episodes, I identified a recurring tension of control present within myself: How can I design a task that will be as open and student-led as possible, while still ensuring that all intended learning objectives will be met? Barbosa and de Oliveira's (2013) five arenas of conflict in task design were used as codes for my second cycle of coding. Applying these new codes allowed me to identify an illustrative example of each conflict and further explore the impact of these tensions on the task implementation.

Measures of Center Task

The task I designed prompted students to stack five different classroom manipulatives (see Figure 1) and determine which type of tower can hold the most items before it topples. This was a repeated measures task because students were instructed to work together to do ten trials for each object and then determine one representative, usual, or typical number for each manipulative. Follow-up prompts and questions were constructed with the intention of discussing several different measures of center and the advantages and disadvantages of each.

Figure 1: Classroom Manipulatives Used for Stacking

Results

For each of the task design conflicts described by Barbosa and de Oliveira (2013), I first illustrate ways in which the conflict manifested in the planning process. Second, I address how my related planning decisions impacted the task implementation. Finally, when the analyses point to a need for related task revisions, the changes are shared as well.

Context

Konold and Pollatsek (1999) hypothesized that data representing repeated measures may be "conceptually the easiest to think about as having central tendencies" (p. 18). As a researcher, I felt drawn to test their hypothesis, but as a teacher, I struggled to think of a manageable and engaging context that would authentically involve repeated measures. This internal conflict is illustrated in the prompt that I gave ChatGPT during planning:

> I want to have students produce a series of repeated measures on something.
>
> Two examples come to mind: (1) How fast can you run around the basketball court? But then we have to deal with students comparing themselves, which will get sticky.
>
> (2) How far does your paper airplane fly? This just gets kids all wild and crazy.

> But what are other ideas like this where it won't take much time to do repeated measures, it's not completely random (not like rolling a die) but there is variation, it won't create problems if the kids compare themselves, and it won't cause too much chaos.

I as researcher articulated the need for an appropriate context to explore with repeated measures that would naturally have some variation, and I offered two contexts that would undoubtedly work mathematically. At the same time, I as teacher drew on classroom experience to know that running laps or throwing paper airplanes would cause unintended management consequences that would distract from the true purpose of collecting a meaningful dataset to analyze. After several rounds of ChatGPT brainstorming followed by clarifying prompts from me, I settled on the stacking context. ChatGPT affirmed this choice by appealing to both of my I-positions:

> The stacking idea is excellent—it's tactile, low-mess, quiet, naturally variable, and totally avoids comparison about physical ability. It also generates rich data: you can count the number of items stacked (a clear, discrete measure), explore patterns across materials, and discuss averages, variation, and even stability factors.

During implementation, the stacking context produced within-object and between-object variation as intended (see Figure 2), providing ample opportunities for rich conversations. As students compared the datasets, they discussed that bears scored decisively low, cubes scored decisively high, and the other three were somewhat harder to order. Additionally, the dice data were bimodal, symmetrical, and had a very small range, while the rhombi had nine different values among just ten trials. As planned, the data collection was easy and accurate, but the participants and I both expressed concern about the large amount of time it took to collect the data. They anticipated that some students would lose interest, while I worried that teachers would not be willing to devote so much class time to data collection. To address this in the next iteration, I plan to increase the group size from three to five students, decreasing the trials each student must conduct and the total time required for this phase of the task.

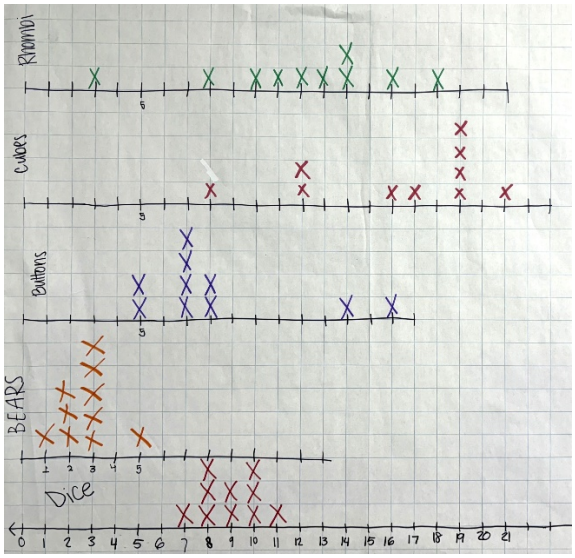

Figure 2: Student-Created Line Plots of Tower Counts for Ten Trials Per Manipulative

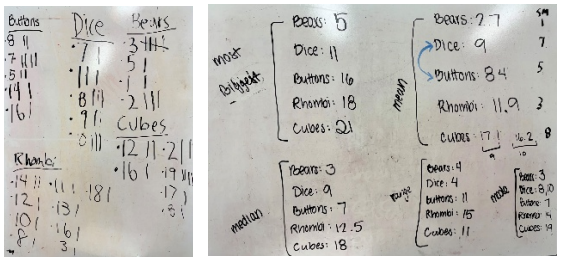
Language

Barbosa and de Oliveira (2013) describe the conflict of language as related to "the level of rigor tied to the task" (p. 546). While designing the task, I as researcher was set on using the words *representative*, *usual*, and *typical* to prompt students towards thinking about measures of center (Mokros & Russell, 1995), but I as teacher wanted to confirm that my directions would be understandable. When I asked ChatGPT to help me revise them for clarity, it suggested giving this instruction to students: "Brainstorm several ways to find a number that could represent your data (for example, the most common number, the middle number, or an average)." While these revised directions might be easier for a student to answer, including the more specific language of *most common* and *middle number* decreases the rigor of the task by identifying ways to numerically represent a dataset. This exchange caused me to recognize that I as teacher value openness in tasks and want to give students as much space to construct their own understanding as possible. I chose not to use ChatGPT's revised, less rigorous version, which reflects my belief in students' abilities to make meaning. My past experiences as a teacher have convinced me that student learning is worth the productive struggle that accompanies rigorous tasks.



When I began planning this task, I imagined implementing it with fifth graders, based on the timeline of our state standards. However, because of easy access to college students in my current role, I chose to first test the task with PSTs. The participants completed data collection and sharing what they initially noticed and wondered, and I prompted them as planned: "It could help to have a single number for each one of those that might represent the data, or be usual or typical for each one of the objects." Immediately, one student answered, "Guys, I think we're finding the average, the mean." I felt slightly perturbed because they went straight to the algorithm, rather than even considering any other possibilities. I had tried to create a more open task with my intentional choice of language, but they approached this moment as if there was one right answer. In revisiting this moment, I recognize another I-position that I occupy: math teacher educator (MTE). I as MTE want my PSTs to experience authentic, elementary, cognitively demanding tasks from the learner perspective to cast a vision for the type of teaching I hope they will do in the future. But I as a new MTE am also still learning the types of modifications necessary for adult students who are experiencing tasks meant to build concepts they have already constructed. Leaning into the idea of multiple I-positions, it still feels acceptable and reasonable to design a task with both fifth graders and future teachers in mind. In the next iteration, which I still plan to do with PSTs, I want to make language adjustments that take their background knowledge into account, but also encourage them to consider how the same lesson could be done in an elementary classroom.

Structure

Structure refers to the "degree of openness" in a task (Barbosa & de Oliveira, 2013), and I experienced a conflict related to structure when deciding how students would record their data. I as teacher and MTE typically advocate for the highest level of openness possible in a task, which in this case would mean allowing students to record their trials and analysis in whatever format made sense to them. On the other hand, I as researcher knew that a purposefully organized table, especially for the measures of center, would be beneficial when trying to facilitate conversations comparing the different objects. I ultimately decided to leave the recording format completely up to students in order to demonstrate the open structure that I as MTE advocate for when helping PSTs plan their own tasks.

As shown in Figure 3 (left and middle), the students chose unexpected structures in both phases of their recording. As they built towers, they recorded the count and added a tally under

the tool name, hence the random order of the values in each list. Each time the tower count was repeated for a tool, an additional tally was added (i.e., 8 | | represents two towers of eight). On the second board, the students recorded measures of center and spread in multiple lists, and they kept the order of the tools constant in each list. Interestingly, when asked to offer ways to improve the overall task, one student suggested they should be given "a way to write our original data" because the tally marks caused some confusion. A different student countered that they appreciated the opportunity to choose their recording structure, and explained that in a full classroom setting, students could benefit from seeing and comparing a variety of student-created methods. In this instance, I argue that not requiring a specific recording format helped me meet the MTE goal of demonstrating the value of an open structure to PSTs. At the same time, I recognize that the students' comparison of the calculated measures on the second board was not as rich as it could have been if a more organized recording method was used. In the next iteration, I plan to discretely fill out a premade table like the one shown on the right in Figure 3 as students calculate their measures of center and spread. When the comparison conversation stalls, I will introduce the additional table to help spark new insights. This revision should maintain the benefits of an open structure while also supporting meaningful discourse.

Item	Mean	Median	Mode	Min	Max	Range
Bears	2.7	3	3	1	5	4
Buttons	8.4	7	7	5	16	11
Dice	9	9	8, 10	7	11	4
Rhombi	11.9	12.5	14	3	18	15
Cubes	16.2	18	19	8	21	11

Figure 3: Student-Created Data Collection (left), Student-Created Data Analysis (middle), and Suggested Format of an Analysis Table (right)

Distribution

For Barbosa and de Oliveira (2013), the distribution conflict refers to tension over the "content to be focused on" in a task (p. 546). I as former elementary teacher expected that the stacking context would be an effective match for the content goal of measures of center. I felt fairly confident that upper elementary students could "reinvent" the concepts of mode and median when prompted to develop a representative number for each stacking object to compare them. Mean could also surface in discussion if students have prior background from completing science experiments or averaging grades, but mean was not intended to be the focus. Distribution was not a conflict for me during the planning of this task because I as elementary teacher and I as researcher both believed in the benefit of delaying the introduction of mean in favor of building a conceptual understanding of mode and median first (Mokros & Russell, 1995).

Unsurprisingly, the task prompted the PSTs to discuss a much wider array of content than just mode and median. During the data collection phase, the students made spontaneous comments that explicitly or implicitly referenced range, variation, and maximum—all of which are related to spread. In addition to discussion about measures of center, their conversations during the analysis phase also covered topics such as consistency or clusters in the data, and how close together or spread out the data were. After creating line plots for each object, one student commented, "When I was learning range, oh my gosh, I had no idea what they were talking

about. But as soon as we started doing this, I could see, okay yeah, the farther apart they are, the bigger the range." This statement and others indicated to me that the PSTs were deepening their statistical content knowledge through this task. Neither the researcher nor the teacher in me is disappointed at the breadth of the content this task evoked. However, I as MTE missed an opportunity to deepen PSTs' mathematical content knowledge because I had not adequately anticipated or planned for the wide range of topics they would discuss. One element I will add to the next iteration of this task for PSTs is an open sort of the measures they calculated in the analysis phase (e.g., mean, median, mode, range, maximum, minimum). I ultimately want PSTs to be able to explain that measures of center and measures of spread are different but interrelated.

Subjects

The final area of conflict, subjects, refers to the "way the task positions students and teachers" (Barbosa & de Oliveira, 2013, p. 546). In other words, task designers must consider the type of interactions the "subjects" will have. Will the task be structured enough for students to progress through it on their own, or will it require perturbations or scaffolding from the teacher at preplanned moments? Overall, I planned the task to fall somewhere in the middle. I wanted students to read and follow the instructions I had prepared without my interference, attempting to confirm that the task could stand on its own and be implemented by other instructors. At the same time, I knew I wanted the freedom to interject in a way that matched our natural classroom interactions—both to help me learn more about the students' understanding and to push their thinking forward. A significant internal conflict surfaced over how I would handle the line plot portion of this lesson (Figure 2). I as researcher envisioned the five line plots that students could create from the data, aligned one over the other. I anticipated that this representation could enrich students' discourse because they would be able to see all distributions at once. However, I could not think of a way to get students to this point, other than, "Now please make a line plot for each object, and stack them." I as teacher felt hesitant to directly prescribe such a specific representation because it did not match the way I positioned myself throughout the rest of the task. I had not resolved this internal subjects conflict by implementation time, so I decided to mostly just wait and see what would happen.

After the students collected the data and shared initial reflections, I showed them a single line plot I had discretely created while they were collecting data. I did not give it a title, and they were tasked with determining which object it matched. This was not much of a challenge for the PSTs, but I am curious if fifth graders without prior knowledge of line plots could do the same. I set the chart aside and told them they could return to it later, still attempting to position students as the main decision-makers. About 20 minutes passed, and I asked them to put on their "teacher hats" and imagine what fifth graders might do when asked to find representative numbers for each object. Immediately a PST said, "I think they would make a chart," and motioned to the single line plot I had created. Though I did not expect this question to necessarily lead us back to the line plot, it turned out to spark a natural, student-led segue into creating the other four graphs. In future iterations of this task, I will purposefully listen for openings like this so that I can still position students as the task drivers as much as possible.

Discussion

In this design-based research self-study, I investigated the following question: *What insights about task design are developed through an initial cycle of designing, implementing, analyzing, and revising a cognitively demanding math task focused on measures of center?* Here I share three main insights.

First, the five arenas of conflict (Barbosa & de Oliveira, 2013) served as an effective framework for analyzing my own task design process when coupled with Hermans' (1996) concept of multiple I-positions. The five conflicts allowed me to focus my analysis of the process and surface the dilemmas and decisions that take place almost subconsciously during task design. The tensions between I as researcher and I as teacher were especially apparent when reviewing my ChatGPT prompts, and this "collaboration" helped me clarify the perspective and values of each I-position. Additionally, the combination of these frameworks revealed another I-position at play, I as MTE, and helped me articulate some of the challenges inherent in designing a task for two very different audiences simultaneously.

Second, this pair of frameworks (Barbosa & de Oliveira, 2013; Hermans, 1996) is also helpful for identifying potential areas of revision within the task design. Barbosa and de Oliveira (2013), when describing the design process, wrote that "the resulting task holds the markers of the conflicts" (p. 547). Extending this idea, I envision revisiting those "markers" during analysis of the task implementation to assess the effectiveness of the decisions I made amidst conflict. In this case, I identified my rationale for using the stacking context, and considered whether or not that context met my expectations during implementation. All mathematical and pedagogical expectations were met except one—time—and this became my focus for task revision.

Finally, intentionally considering multiple I-positions and five conflicts during planning may enhance future task design endeavors. For example, consciously acknowledging my MTE and elementary teacher positions during planning should prompt me to adjust appropriately and purposefully for my audience. Additionally, I can imagine myself considering the five conflicts to self-check that I have been intentional about aspects of the task design and its delivery.

Conclusion

In this study, I report on the first iteration of a design-based research self-study on the design of a measures of center task. I combined the theories of Barbosa and de Oliveira (2013) and Hermans (1996) to analyze my design process and identify areas of improvement in the task. This novel combination of theories contributes to the field of math education and task design by extending the conflicts framework from a collaborative setting to an individual's internal, dialogical tensions. Additionally, I argue that the conflicts framework may be helpful in organizing one's thoughts and intentions during the planning process and assessing the effectiveness of design decisions after implementation. Teachers and other task designers may find that clarifying or justifying their choices related to context, language, structure, distribution, and subjects prompts them to address overlooked aspects of the task during planning or refine task elements based on the values of their various I-positions.

I as researcher am eager to conduct the next round of this design-based research project with PSTs, implementing the revisions that my framework and analysis helped me develop. In this round, I used Barbosa and de Oliveira's (2013) five conflicts without critique, looking for evidence of each conflict within my planning process. In future rounds, I plan to consider the possibility of conflict arenas that they have not named, as well as other I-positions that may be at work during my task design process. Additionally, the findings reported here are limited by a small sample size of three students. Implementing the task with multiple groups of students in a classroom setting will provide further opportunities for task refinement.

THE CONNECTION BETWEEN PRODUCTIVE STRUGGLE AND A SENSE OF BELONGING

Mary Ramos-Duke
Boise State University
maryramosduke@boisestate.edu

Monica Anthony
Georgia Gwinnett College
manthony5@ggc.edu

This theoretical brief explores the connection between mathematical identity components (i.e., mathematical authority and agency), productive struggle, and a sense of belonging. Specifically, the role of a sense of belonging and productive struggle in students' comfort with struggling in whole groups or small collaborative groups. We present a theoretical model for not only creating mathematical tasks to foster a sense of belonging, but also an environment conducive to thickening a sense of belonging over time, allowing students to become comfortable with the vulnerability needed to routinely engage in ambitious mathematics.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Culture and Asset-Based Pedagogies; Instructional Activities and Practices

Both a sense of belonging and opportunities for productive struggle have been identified as critical to students' engagement in mathematics. While recent works have addressed the cultivation of a sense of belonging (National Council of Teachers of Mathematics [NCTM], 2025) and productive struggle (Jarry-Shore & Richardson, 2024) separately, it is imperative to discuss a more purposeful approach to these constructs beyond lessons of interest or names in word problems (Gutiérrez, 2012). Productive struggle is crucial for students' mathematical learning (Hiebert & Grouws, 2007; Jarry-Shore & Richardson, 2024; Warshauer, 2015). Since ambitious mathematics promotes student collaboration, students need to form relationships and develop a comfort with productive struggle (Jarry-Shore & Richardson, 2024; Langer-Osuna, 2017). Thus, fostering students' sense of belonging in mathematics is necessary for students to become comfortable with the vulnerability required for productive struggle in collaborative settings, especially for students from culturally and linguistically diverse communities, who have often been positioned as mathematically deficient (Buli, 2025; Civil, 2007; Gutiérrez, 2012).

In this brief, we propose a theoretical model for attending to students' mathematical learning while humanizing the need to productively struggle with problems in collaborative classroom interactions. Furthermore, we discuss a sense of belonging as both an outcome of productive struggle and a condition for it, and the complexity of the components needed for this to occur. While a sense of belonging can be cultivated through caring relationships with students or leveraging Funds of Knowledge (Moll, 2019) in isolated mathematics tasks, we argue there is an astounding need to strengthen belonging through routine practices and over time, to not only cultivate a sense of belonging, but to repair possible endured bias or traditional approaches to mathematics instruction (Aguirre et al., 2017; The Collaborative for Academic, Social, and Emotional Learning [CASEL], 2022; Cohen, 2022; Thanheiser et al., 2025).

Productive Struggle

Student learning necessitates productive struggle (Hiebert & Grouws, 2007; NCTM, 2014). When students wrestle with and work through cognitively demanding tasks, they develop a stronger understanding of mathematical concepts (Hiebert & Grouws, 2007). Therefore, students should be given ample opportunities to engage in cognitively demanding mathematics tasks that promote productive struggle (NCTM, 2014; Sengupta-Irving & Agarwal, 2017; Warshauer,

2015). In this paper, we are particularly interested in Jarry-Shore & Richardson's (2024) typologies of struggle, including mathematical and social aspects of struggle during collaborative tasks.

A Sense of Belonging, Authority, and Agency

A student's sense of belonging refers to their feelings of inclusion and value in both the classroom and the larger mathematics community (NTCM, 2025). Students of all genders, languages, abilities, races, and ethnicities have the right to feel a sense of belonging in school and in mathematics (CASEL, 2022; Cohen, 2022). Watson (2023) identifies five factors of belonging: (1) You see me, (2) I see myself, (3) Others see me, (4) I am valued, and (5) I can grow. Thus, students' sense of belonging hinges on being seen by both the teacher and their peers as a valued member of the community. For students to establish themselves as participants in the community, educators must share authority with them. Mathematical *authority* resides with whoever is regarded as mathematically legitimate (Dunleavy, 2015). Teachers delegate authority to students when students decide which solutions and ideas are mathematically valid and why (Gresalfi & Cobb, 2006). Thus, supporting students in developing a sense of mathematical legitimacy within themselves and amongst their peers (Langer-Osuna et al., 2017), and ultimately, affording the students the space and ability to use their *agency* to solve problems as they see fit (Dyer et al., 2023). When students have the opportunity to engage in instruction that provides regular opportunities for student agency, they are more likely to share their mathematical thinking and ideas, and to advocate for representations that make sense to them in public and group settings (Aguirre et al., 2013; Ramos-Duke, 2024; Turner, 2003).

The Connection Between Productive Struggle and a Sense of Belonging

We propose that a sense of belonging is not just an outcome of productive struggle, but a condition for it in the mathematics classroom. Furthermore, we recognize Funds of Knowledge (FOK; Moll, 2019), Rights of the Learner (ROTL; Kalinec-Craig, 2017), and Social-Emotional Learning (SEL; CASEL, 2022) as supportive constructs in the development of productive struggle and a sense of belonging amongst mathematics students in the classroom. Funds of knowledge, the premise that students walk into the classroom with knowledge (e.g., in different languages, contexts, interests); thus, leading to planning and constructing mathematics classroom environments with asset-based views. Additionally, Kalinec-Craig's (2017) first right, *You Have the Right to be Confused*, establishes that productive struggle is necessary for students to feel supported without "judgment or ridicule" (p. 5). Socio-emotional learning helps students develop self-management, self-awareness, responsible decision-making, relationship skills, and, importantly for group work, social awareness (CASEL, 2022; Joswick & Taylor, 2022). Thus, supporting a sense of comfort and belonging while working together and productively struggling through mathematical problems.

The Thickening of Sense of Belonging and Productive Struggle Over Time

The model in Figure 1 depicts a thickening of concepts over time through the implementation of asset-based practices and frameworks. Turner (2003) describes students' mathematical agency as a fragile construct that necessitates routine day-to-day attention. Therefore, because students need to use their mathematical agency to engage in productive struggle in collaborative settings to solve cognitively demanding tasks, we extend this notion to the whole model. Thus, mathematical authority, agency, productive struggle, and a sense of belonging are fragile. This fragility is lessened by the asset-based practices and frameworks used to build a positive relationship and a sense of belonging with(in) mathematics (Aguirre et al., 2013; Cohen, 2022).

Therefore, if mathematical practices routinely support students' mathematical authority, agency, ability to productively struggle, and a student's sense of belonging, and do so purposefully in tandem, these student-centered concepts will thicken and strengthen over time.

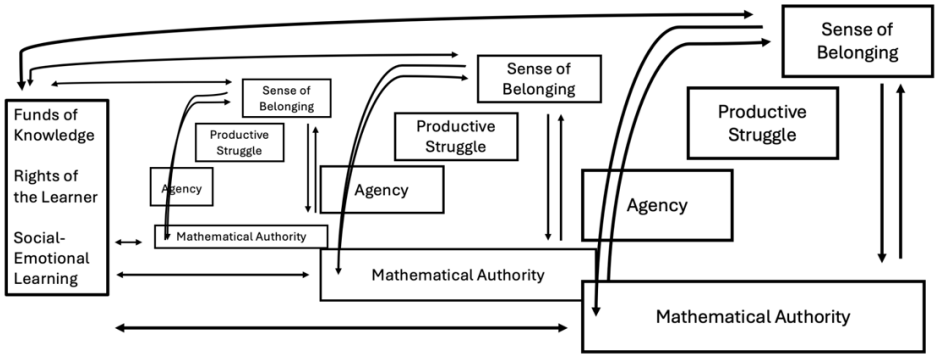

Figure 1: Building a Sense of Belonging (CASEL, 2022; Cohen, 2022; Dunleavy, 2015; Hiebert, J., & Grouws, 2007; Jarry-Shore & Richardson, 2024; Kalinec-Craig, 2017; Langer-Osuna et al., 2017; Moll, 2019; Turner, 2003)

Productive Struggle in Groups Necessitates Positive Relationships

Working together in mathematical groups requires positive relationships (Langer-Osuna et al., 2021). Furthermore, productive struggle in collaborative settings requires that each student be heard and included (Jarry-Shore & Richardson, 2024). To support productive struggle within groups, we link CASEL (2022)'s notion of a sense of belonging, a student's sense of being part of the community or a group, with seven elements identified by the Annie Casey Foundation (2021). These elements aim to support equity and inclusion and address the fundamental human need to belong: (1) an extravagant welcome (You Belong!), (2) being seen, (3) being affirmed, (4) culture, (5) being heard, (6) self-determination, and (7) a focus on well-being. This link brings to the surface elements necessary for students to engage in collective productive struggle in a group setting, rather than hang back or abandon a problem.

When students even feel slightly as if they do not belong, there can be missed opportunities for learning (Annie E. Casey Foundation [AECF], 2021). According to Walton and Cohen (2007), "One of the most important questions that people ask themselves in deciding to enter, continue, or abandon a pursuit is, 'Do I belong?'" (p. 94). Moreover. The Annie E. Casey Foundation (2021) states that cultivating belonging requires addressing culture and identity. Therefore, to support positive relationships and address elements of belonging in mathematics groups (AECF, 2021; Langer-Osuna et al., 2021), we intertwine Funds of Knowledge, the Rights of the Learner, and Social-Emotional Learning (CASEL, 2022; Kalinec-Craig, 2017; Moll, 2019). In our theoretical model, a sense of belonging is purposefully cultivated in a mathematics environment that is steeped in respect for the knowledge (FOK) and culture students bring to the group; students are routinely afforded the ROTL in the group; and students are supported in developing the emotions (SEL) conducive to building relationships, in order to activate the authority and agency needed to productively struggle together as a group when solving mathematics problems (CASEL, 2022; Cohen, 2022; Jarry-Shore & Richardson, 2024; Kalinec-Craig, 2017; Langer-Osuna, 2021; Moll, 2019; NCTM, 2014; Ramos-Duke, 2024; Saba & Johnson, 2025). Thus, the social aspects of struggle in groups are fostered, including "the need to be heard and included" (Jarry-Shore & Richardson, 2024).

Discussion

We acknowledge that the theoretical model discussed in this brief is only a portion of the complex ecosystem required to support the development of a sense of belonging. However, we hope to emphasize the connection between productive struggle and a sense of belonging, as both concepts are crucial for mathematical progress and growth. As K-16 educators, we see this model as especially salient for multilingual learners and others who have traditionally been harmed in mathematics classrooms, and who might not be comfortable with the vulnerability required to engage in productive struggle in a group setting (Aguirre et al., 2013; Ramos-Duke, 2024; Jackson et al., 2017). Therefore, routine, persistence, and tending to the complex nature of developing a sense of belonging are imperative. Although a sense of belonging can be supported through math tasks with relatable contexts or connections to students' lives and interests, teachers need to do the heavy lifting of creating a culture of belonging. This culture must develop and thicken over time.

Implication and Future Use of Our Model

This emergent theoretical framework is intended to guide research, teacher preparation, and the longitudinal implementation of productive struggle in K-16 mathematics courses. As a crucial aspect of learning, productive struggle, and a potent part of collaborative culture, a sense of belonging seems necessary for students to succeed and engage in ambitious mathematics and cognitively demanding tasks.

Acknowledgments

We would like to thank the Productive Struggle Working Group, who helped us think through earlier versions of this framework.

HOW DO ELEMENTARY TEACHERS INCORPORATE NON-DIGITAL MATH GAMES INTO INSTRUCTION? A MIXED METHODS STUDY

Katelyn Suchyta
University of Maine
katelyn.suchyta@maine.edu

Justin Dimmel
University of Maine
justin.dimmel@maine.edu

Sara M. Flanagan
University of Maine
sara.flanagan@maine.edu

This convergent mixed-methods study examined how K-2 teachers in Maine use non-digital math games to support equitable mathematics instruction, grounded in Universal Design for Learning (UDL) and embodied cognition. Survey data from 127 teachers revealed that 87% use non-digital games at least weekly, primarily to foster engagement, fluency, conceptual understanding, and differentiation. Interviews with three teachers aligned with survey findings and showed that games are adapted to support diverse learners, with a preference for non-digital over digital activities. Despite barriers such as time and resources, findings suggest non-digital math games are often embedded within core instruction and are adapted with practices aligned with UDL. Implications point to the need for educators' professional learning around non-digital math games and further research to deepen their instructional impact.

Keywords: Elementary School Education, Instructional Activities and Practices

Introduction

Mathematical games have been used in classrooms for decades, tracing back to Dienes' theory of learning mathematics (Dienes, 1963). According to Dienes (1963), games provide playful and embodied experiences, making mathematical concepts more tangible and accessible to learners. Ernest (1986) further advocates for the use of games, highlighting their effectiveness in teaching mathematics, particularly for practice, acquiring concepts, developing problem solving skills, and motivation. Mathematical games include both digital (use technology) and non-digital formats and are defined as activities that teach math skills through skill, strategy, rules, and interactive play (Russo et al., 2024). A classic non-digital math game is *Shut the Box*, in which players use dice and arithmetic operations to close numbered tiles, with the goal of closing all the tiles on the box (Stebler et al., 2013). This simple design affords opportunities for players to strengthen their fact fluency through haptic-tactile interaction and strategic thinking. Design-based researchers, cognitive scientists, and teachers, especially those working in alternative or experimental settings (e.g., Montessori Schools), have long heralded the educational value of math games. In a systematic review of 43 empirical studies focusing on K-12 math games, Pan et al. (2022) found that learning games in K-12 mathematics education are generally effective in enhancing math learning, however, they highlight the need for more research examining game design and use to support meaningful mathematical understanding. Similarly, Russo et al. (2024) analyzed 32 studies and found that math games are potentially effective for developing math proficiencies and improving motivation towards math. Math games also have a multifaceted role in mathematics teaching practices (Applebaum, 2025). Buchheister et al. (2017) suggest math games have the potential to meet the needs of individual students, "bridg[ing] the type of instruction alongside the needs of the individual student to positively impact students' mathematical development" (p. 12).

While research supports the effectiveness of math games broadly, an important distinction emerges between digital and non-digital formats, particularly in how teachers use them instructionally and how they support students' development of mathematical understanding. In a

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

recent study that surveyed Australian primary school educators, teachers reported a clear preference for non-digital games, emphasizing their affordance of collaboration, communication, use of manipulatives, and flexible differentiation (Russo et al., 2023). Even as schools in the United States of America work to close the digital divide and more schools have access to technology, non-digital games remain a powerful, accessible, and pedagogically valuable tool for fostering mathematical thinking and engagement (Hall et al., 2024). Physical tools allow students to touch, feel, grip, spatially interact, and engage socially (Shin et al, 2017). This is further supported by theories of embodied cognition emphasizing that mathematical understanding is grounded in physical interaction and manipulation with the environment (de Freitas & Sinclair, 2014). Consequently, non-digital math games may provide unique opportunities for children to discover mathematical relationships, develop strategic reasoning, and construct understanding through embodied, social, and multimodal interactions (Tran et al., 2017).

However, despite growing recognition of these affordances, they remain on the periphery of many teachers' instructional practices and relatively little is known about how teachers incorporate non-digital games into everyday mathematics instruction or adapt them to support the diverse needs of learners. Orim and Ekwueme (2011) found that teachers feel games are a waste of time because they are too time consuming and unmanageable. Teachers also face constraints due to lack of resources and limited training in effectively implementing games in their classrooms (Applebaum, 2025). Contrary to this, the Maine Education Policy Research Institute found that elementary educators "suggested more hands-on materials and games for concrete representations and engagement in learning and less reliance on paper worksheets" (Lech et al., 2024, p. 52). Therefore, the current state of the research suggests a disconnect between the growing body of scholarship highlighting the instructional potential of math games and their integration into everyday classroom practice. Therefore, the purpose of this study was to investigate how elementary teachers incorporate non-digital mathematics games into their teaching and adapt them to meet diverse student needs. This study's focus on non-digital math games is important because it highlights hands-on, technology-free, socially interactive, and differentiated learning experiences without the use of technology.

Purpose of the Study and Research Questions

This study explored how primary grade teachers (K-2) use non-digital math games to support student learning. Specifically, the researchers investigated teachers' instructional goals, adaptations, and perceptions of the benefits and challenges of using math games. The findings contribute to a deeper understanding of both the pedagogical role of non-digital math games and the ways teachers tailor them to meet diverse student needs. The following research questions guided this study:

1. How frequently do teachers use non-digital math games, and what pedagogical aims guide their use?
2. How do teachers implement and modify non-digital games to support all students, and what factors support or constrain their use?

Theory: UDL and Embodiment

We frame our inquiry into teachers' use of non-digital mathematics games from the perspective of Universal Design for Learning (UDL; Meyer et al., 2014). UDL came from the CAST Center in Boston in the 1980s and is an educational framework for instruction that is rooted in the learning sciences and neuroscience (Meyer et al., 2014). UDL encourages

"mathematics teachers to move from deficit-focused pedagogies that seek to "fix" children toward asset-based pedagogies" (Lambert, 2021, p. 662). Since all students vary in how they see, hear, move, remember math concepts, focus attention, and respond emotionally to mathematics, teachers must account for this learning variability. Only by doing so can they effectively support mathematical learning of all students (Meyer et al., 2014; Rose, 2017). The goal of UDL is to develop expert, strategic, and lifelong learners, rather than focusing on content.

Non-digital math games align closely with the UDL framework by offering flexible, multimodal entry points to mathematical ideas. Through physical manipulatives, visual cues, oral language, movement, and choice of strategies, games provide multiple means of representation and action, allowing students to access mathematical ideas in ways that align with their strengths. Importantly, games make student thinking visible through moves, talk, and decisions, creating rich opportunities for equitable feedback and formative assessment. Math games also position students as capable problem solvers, support productive struggle, and affirm diverse ways of mathematical understanding. Therefore, through a UDL framework, non-digital math games have the potential for helping all learners, particularly students with disabilities, develop positive mathematical identities and sustained engagement with mathematics.

This study is grounded in the theoretical perspective advanced by de Freitas and Sinclair (2014) conceptualizing mathematical learning as an embodied, material, and relational process rather than a purely cognitive one. From this perspective, mathematical thinking emerges through the dynamic entanglement of learners' bodies, gestures, spatial movement, and material artifacts within learning environments (de Freitas & Sinclair, 2014). This framing is particularly salient for early elementary learners, whose mathematical understanding is closely tied to sensorimotor experience and physical engagement with their environment.

Non-digital mathematics games in K-2 classrooms provide a powerful context for examining these material entanglements. Such games often involve manipulatives, spatial organization, turn-taking, bodily movement, and peer interaction. For example, when students count by moving along a number line, build structures with blocks to compare quantities, or use hand gestures to represent numerical relationships, mathematical ideas are enacted through embodied practice. In these moments, bodies, materials, and mathematical concepts co-produce understanding. By using de Freitas and Sinclair's (2014) framework, this study examines how K-2 teachers leverage non-digital math games to create embodied mathematical experiences and how these practices reflect underlying beliefs about how children learn mathematics. This lens allows for an analysis of teaching practices that attends not only to instructional strategies, but also to how classroom materials, spatial arrangements, and bodily actions shape opportunities for mathematical thinking.

Methods

This study employs a convergent mixed-methods design (Tashakkori & Teddlie, 2016) to investigate K-2 teachers' use of non-digital mathematics games, with a particular focus on how teachers design, adapt, and facilitate games to support equitable mathematical learning, including for students with disabilities. Through the convergent mixed methods design, we simultaneously collected and analyzed both quantitative data from surveys and qualitative data from interviews, then merged the results to compare findings, identify alignment or divergence, and gain a more comprehensive understanding of our research questions (Tashakkori & Teddlie, 2016).

Survey Participants

A total of 127 K-2 teachers in Maine completed a survey that focused on how they use non-digital math games in their classrooms. Although Maine represents a convenience sample, its

highly localized school systems and the instructional autonomy afforded to teachers provide a valuable context for this study. Maine educators' perspectives offer an opportunity to surface a diverse range of perspectives on game-based learning practices in a rural state. Participants included classroom teachers (n = 71), special education teachers (n = 37), math interventionist (n = 10), math coaches (n = 3), gifted and talented teachers (n = 3), behavior interventionists (n = 2), and an education technician (i.e., paraeducator; n = 1). These K-2 teachers indicated they worked in rural (n = 78), suburban (n = 37), or urban (n = 12) settings. Overall, participants were relatively experienced teachers with 70% (n = 89) of participants having over 10 years of experience.

Survey Design

The survey was distributed using Qualtrics, an online survey platform to reach all K-2 teachers in the state of Maine. The survey defined non-digital mathematics games as an activity that: "has specific mathematical cognitive objectives; requires students to use mathematical knowledge to win the game; is enjoyable and with potential to engage students; is governed by a definite set of rules and has a clear underlying structure; involves a challenge against either a task or an opponent(s) and interactivity between opponents; includes elements of knowledge, skills, strategy, and/or luck, but not luck alone; has a distinct finishing point;" and "does not employ a digital device or tool to support the playing of the game" (Russo et al., 2024, p. 3). The survey questions were adapted from Russo et al. (2021) and focused on frequency and pedagogical aims for playing non-digital math games.

Survey Analysis

Survey responses were analyzed descriptively and are presented in the following section. Frequencies and percentages were calculated for each survey item and used to identify common patterns and trends across participants' responses. No statistical analyses were conducted, as the survey data were used primarily to contextualize subsequent qualitative analyses.

Interview Participants

Fifteen K-2 Maine teachers agreed to participate in follow-up interviews after completing the survey. This paper focuses on three of these teachers, whose backgrounds are presented in Table 1. These participants were purposefully selected to illustrate a range of perspectives on the use of math games across diverse teaching roles, levels of experience, and educational settings.

Table 1: Background of Three Participants: Teacher A, Teacher B, and Teacher C

	Teacher A	Teacher B	Teacher C
Position	Grades K-2, Math Interventionist	Grade 2, General Education	Grades 1-2, Special Education
Teaching Experience	35th year teaching	19th year teaching	2nd year teaching
Type of School	K-2 School	K-8 School	PreK-2 School
Student Population	300 Students	360 Students	600 Students
School Setting	Suburban	Rural	Suburban
Frequency of playing non-digital math games	"I do multiple times a week… at least two times a week"	"I shoot for five times a week… at least three days"	"I use games almost everyday"

Interview Design

Semi-structured, one-on-one interviews were conducted virtually over Zoom. To have a more in-depth understanding of teachers' experiences, interview questions were designed by transforming selected survey items into more open-ended prompts, allowing teachers to elaborate on their instructional practices related to implementing non-digital math games. Prompts were aligned with the Universal Design for Learning (UDL) framework to explore how teachers provide multiple means of engagement, adaptations, and differentiation. For example, the interview protocol included questions such as, "Describe how you use non-digital math games in your classroom," and "Thinking about students who struggle in math, how do you adapt math games to support their learning?"

Interview Analysis

Interviews were thematically analyzed through iterative coding, theme development, and ongoing interpretation of patterns across participants' responses (Braun & Clarke, 2021).

Survey Results

Survey responses from 127 K-2 teachers in Maine were analyzed to describe how teachers use non-digital math games to support their mathematics instruction. Teachers were asked to report how frequently they played non-digital math games, ranging from "all the time" to "never." Table 2, below, summarizes these results. Overall, 87% of participants (n = 110) reported playing non-digital math games at least once per week in their classrooms, while only one participant reported never playing non-digital math games.

Table 2: Frequency Teacher Reported Playing Mathematical Games

Frequency of math game use	Frequency (n=127)	Percent
All the time (e.g., about 4–5 times per week)	34	27%
Often (e.g., about 2–3 times per week)	48	38%
Sometimes (e.g., about once per week)	28	22%
Rarely (e.g., less than once per week)	16	13%
Never	1	1%

Teachers were also asked how frequently they incorporated non-digital math games into different components of their classroom routines and math lessons. The same frequency scales were used, ranging from "all the time" to "never." Table 3, below, summarizes these results. 57% of participants indicated that they use non-digital math games to support fluency practice either all the time or often. Furthermore, 48% of participants indicated that they use non-digital math games to support students who are low achieving in math either all the time or often. Using math games outside of math lessons, as a warm-up activity in a math lesson, and/or at the closure of a math lesson were less frequently reported by teachers.

Table 3: Frequency of Ways Teachers Use Mathematical Games

Component of classroom routines or math lessons	All the time (4–5 times per week)	Often (2–3 times per week)	Sometimes (about once per week)	Rarely (less than once per week)	Never
Outside of my math lessons	12%	22%	31%	24%	12%
As a warm-up activity in a math lesson	8%	22%	30%	30%	10%
As the main learning activity in a math lesson	7%	15%	45%	21%	13%
As the closure activity in a math lesson	11%	21%	30%	20%	17%
To support fluency practice	20%	37%	28%	12%	3%
To support students who are low achieving in math	16%	32%	30%	16%	6%

Teachers were asked to evaluate the effectiveness of non-digital mathematics games for 11 pedagogical aims on a 5-point Likert scale, ranging from strongly disagree to strongly agree. Table 4, below, summarizes the results. In general, teachers indicated that non-digital math games were effective for achieving the pedagogical aims outlined in the survey. The vast majority (97%) of participants indicated that they either strongly agreed or agreed that non-digital games were effective for engaging students in mathematics lessons. Furthermore, the majority of participants also indicated that they either strongly agreed or agreed that math games were effective for building procedural fluency (88%), conceptual understanding (91%), mathematical reasoning (88%), and problem-solving skills (91%), and for differentiating (90%). In contrast, only 54% of participants indicated that they either strongly agreed or agreed that math games were effective for supporting connections between home and school.

Table 4: Teacher Agreement on Effectiveness Across 11 Pedagogical Aims

Pedagogical Aim	Combined Agree or Strongly Agree	Only Strongly Agree	Only Agree
Engaging students in math lessons	97%	49%	48%
Building procedural fluency	88%	31%	57%
Maximizing on-task behavior	81%	28%	53%
Building conceptual understanding	91%	31%	60%
Generating rich mathematical discussions	73%	17%	56%
Building mathematical reasoning	88%	33%	55%
Differentiating for different performance levels	90%	38%	52%
Building problem-solving skills	91%	40%	51%
Focusing students on important mathematical ideas	85%	30%	55%
Assessing student learning	76%	24%	53%
Supporting connections between home and school	54%	16%	38%

Interview Results

Pedagogical Aims for Using Non-Digital Math Games

Teachers' responses regarding their use of non-digital math games aligned with trends identified in the survey data. Their responses included using games to support fact fluency, serve as warm-ups, increase student engagement, provide hands-on learning opportunities, and support students who struggle in mathematics through differentiation. Teachers described using games flexibly within math lessons, across small-group and independent contexts, and as part of broader instructional routines. For example, Teacher A explained, "I will embed them in the lesson, typically at the beginning, just to warm up our brains, to have something fun to get us started, and then it's really nice when I can tie it into the lesson later on." Consistent with prior research, teachers in this study viewed games as effective tools for engaging students in meaningful mathematics (Hall et al., 2024; Russo et al., 2023; Tran et al., 2017). Extending this literature, the findings illustrate how non-digital games are embedded within and integrated across daily classroom instructional routines.

Teaching Practices

Across all three teachers, there is strong alignment with posing purposeful questions, eliciting and using evidence of student thinking, and facilitating discourse. For example, Teacher B explained, "I try to go around and help facilitate with each group and ask prompting questions." Together, their statements illustrate how non-digital math games can serve as rich contexts for student-centered, discussion-driven, and conceptually focused instruction. These practices are also consistent with the National Council of Teachers of Mathematics' (NCTM) vision of effective mathematics teaching, which emphasizes that high-quality mathematics instruction should foster conceptual understanding, procedural fluency, strategic competence, adaptive reasoning, and productive disposition (NCTM, 2014; NCTM, 2020).

Adaptations to Support Students

Across all three teachers, adapting math games reflects strong UDL-aligned practices by reducing unnecessary barriers to participation, adjusting challenges to support productive engagement, offering flexible representations and supports, and prioritizing student success as a pathway to deeper learning. For example, Teacher C described, "If there is a student that learns better with a number line, there's an adaption for that game." Together, these adaptations illustrate how non-digital math games can be flexibly designed and implemented to support inclusive, learner-centered mathematics instruction consistent with UDL principles. Additionally, all three teachers' adaptations support embodied mathematical learning by engaging students in physical and social interactions with game materials (e.g., moving pieces, using number lines, and negotiating turns). Consistent with de Freitas and Sinclair's (2014) perspective, these teachers' adaptations create conditions for mathematical understanding to emerge through the entanglement of students' actions, social relationships, and material artifacts.

Preference for Non-Digital Games Over Digital Activities

All three teachers' perspectives further illuminate why non-digital math games remain central in their mathematics instruction, especially when comparing it with technology or digital activities. As Teacher A explained, "I never use digital math games with my students…the math games that we play need to be interactive … I need to be watching as we play games" (Teacher A), emphasizing the importance of interacting with students and observing students' thinking in real time. Similarly, Teacher C described how "they look at screens all the time," and explained that digital activities are "really hard to monitor" and their "just doing it solo, online, zero interaction," contrasting this with hands-on experiences where students work with partners,

"explain[ing] why they know what they're doing" (Teacher C). Together, all three teachers' emphasize the importance of and preference for non-digital math games.

Barriers to Implementation

Across interviews, teachers described consistent barriers to implement non-digital math games in their classrooms including time, challenges with student behaviors, access to ready-made resources or shared materials, collegial collaboration, funds, and support from administration. Teachers valued curated game kits and shared repositories that reduced preparation demands and increased instructional quality. Teacher A even noted the value of "the plethora of games that we now have with the Building Fact Fluency [Kit], instead of me hunting, trying to find games. I really like the Building Fact Fluency games, because it's not just math facts, there's also strategy involved." Guidance varied by context and experience, ranging from school-supported initiatives and coaching cycles to informal mentoring and RTI-based supports. Behavioral challenges required ongoing adaptation, including modifying rules, scaffolding emotional regulation, or pausing gameplay altogether. For example, one teacher explained, "For probably at least a third of the students in here, it was too hard, so I ended up changing the rules" (Teacher B). Therefore, teachers' wishes centered on increased administrative support, dedicated time to design and observe game-based instruction, shared spaces for resource creation, and funding for physical games rather than digital platforms, highlighting a desire for systemic alignment to sustain equitable, effective implementation.

Discussion and Implications

This study contributes to the growing body of research on the pedagogical value of non-digital math games in early elementary classrooms. Findings from surveys and interviews suggest that non-digital math games are frequently embedded within core instructional routines in K-2 classrooms and have important implications for equitable mathematics instruction. The findings from this study provide evidence that teachers' practices using non-digital math games often align with the UDL framework by offering multimodal access to math content, while also supporting embodied learning by connecting mathematical understanding to sensorimotor experiences and physical engagement with the environment. Together, these affordances create more accessible and inclusive opportunities for students to participate in mathematical learning.

Despite growing pressure to adopt digital technologies, there remains a persistent preference for non-digital approaches. Survey and interview data suggest educators intentionally avoid digital activities and prefer activities that requires interactive, hands-on play where teachers can observe thinking and facilitate social interactions. Research supports these findings, indicating that educators not only use non-digital math games more often than digital games, but they also express a clear preference for them to support mathematics teaching and learning (Russo et al., 2024). Furthermore, while digital tools are increasingly embedded in early mathematics instruction, excessive screen exposure may limit opportunities for hands-on, social, and movement-based learning that are developmentally important in the early grades (Munzer et al., 2026). Non-digital math games offer an appropriate alternative by providing interactive mathematical experiences without reliance on screens. Moreover, as artificial intelligence (AI) becomes more deeply integrated into educational tools, opportunities for embodied and sensory-motor engagement may become further limited. This shift underscores the continued importance of tactile, hands-on learning experiences, particularly in elementary classrooms, where embodied interaction plays a critical role in mathematical learning. Accordingly, the intentional design of non-digital learning activities is increasingly essential to ensure that they meaningfully support mathematical development within AI-driven educational contexts.

However, while teachers reported frequent use of games, particularly to support low-achieving students, they were not always leveraging them to their fullest, such as by extending them into rich mathematical investigations that promote deeper reasoning (Russo & Russo, 2020; Russo et al., 2021). Therefore, further research is needed to identify how non-digital math games can best function across diverse classroom contexts and student populations. This paper also highlights a need for educator professional learning that supports teachers in critically examining how to leverage non-digital math game interventions as a component of teaching mathematical problem solving, "in which the main goal is for students to develop a deep understanding of mathematical concepts and methods" (Gray et al., 2025, p. viii).

The findings from this study also provides a strong foundation for future design-based research (DBR) grounded in Math UDL (Lambert, 2021). The next phase of this work will involve collaborative partnerships with K-2 teachers to iteratively co-design, implement, and refine non-digital math game interventions that align with UDL Math principles and classroom realities. Through DBR, educators and researchers can work together to create engaging, accessible, and meaningful mathematical experiences that position all learners as capable participants in rich mathematics learning.

POSITIONING STUDENTS AS MATHEMATICS DOERS: TEACHER DISCOURSE AND LEARNING OPPORTUNITIES IN GHANAIAN ELEMENTARY SCHOOLS

Joyce Nsiah Asante
Texas State University
dfq3@txstate.edu

This study investigates how elementary school teachers from Ghana position their students as mathematics doers and how such positioning shapes instructional practices. Using positioning theory and sociocultural learning theory, the study analyzes semi-structured interviews and classroom observation data from five teachers. The analyses trace connections between teachers' beliefs about students' ability and their communicative acts and resulting teaching moves. The findings reveal three positioning practices: inclusive, mixed, and restrictive, that mediate students' access to mathematical reasoning and participation. These are not fixed traits but interactional stances that emerge during instruction. The study highlights the role of teacher discourse in shaping learning opportunities and suggests making positioning an explicit focus of professional development.

Keywords: Positioning Theory, Teacher Discourse, Inclusive Positioning, Restrictive Positioning

Introduction

Teachers play a major role in how learners respond to mathematical learning. They help students develop problem-solving skills, connect math to real-world contexts, and build confidence through meaningful feedback (Mathematics, 2020). How teachers communicate, deliver instruction, and facilitate classroom discussions significantly influences how students see themselves and engage with mathematics (Boaler, 2013; Davis, 2018; Kofi & Chaiklin, 2015). Research shows that when teachers encourage open dialogue, pose thoughtful questions, and validate student contributions, students' participation, confidence, and mathematical abilities improve (Davis, 2018). This research positions classroom interactions as essential in mathematics teaching and learning and meaning-making.

At the core of mathematics education is the relationship between how math is discussed and how students are positioned (Bishop, 2012; Langer-Osuna, 2011). Bishop shows that students' mathematical identities are formed and reinforced through classroom interactions. Mathematical discourse includes how teachers and students represent, think, talk, agree, and disagree when working on math problems (Moschkovich, 2007). Classroom discourse not only conveys math content but also positions students as either competent, valued thinkers or as struggling, passive learners, depending on teacher expectations and interactions (Moschkovich, 2002; Turner et al., 2013). Thus, discourse extends beyond learning terminology and involves participating in mathematical practices and ways of thinking.

Teachers are instrumental in positioning students in the classroom. Teacher positioning refers to how teachers perceive and interact with students, assign roles, and shape identities that affect students' participation and learning (Turner et al., 2013; Yamakawa et al., 2009). This includes how teachers frame expectations, provide feedback, and manage the classroom dynamics. These interactions can lead to either positive positioning,, for example, when a teacher acknowledges a student's effort and potential, positioning them as a capable and valued, or negative positioning, when a teacher repeatedly points out errors without constructive feedback, positioning the student as a struggling or passive learner (Davies & Hunt, 1994; Suh et al., 2013). Positioning

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

students as competent involves using specific, explicit affirmations to recognize that they have contributed something meaningful to the classroom community (Davies & Hunt, 1994; Gallagher et al., 2024).

In Ghana, recent curriculum reforms promote student-centered, discourse-rich math instruction (National Council for Curriculum Assessment [NaCCA], 2019), but little is known about how teachers position students in practice. This study addresses that gap by qualitatively examining how Ghanaian elementary teachers understand and enact positioning of themselves and their students as "math doers and thinkers," and the instructional strategies and classroom interactions they operate.

Conceptual Framework

This study draws on positioning theory and sociocultural perspectives on mathematics education (Lerman, 2000) within Ghana's educational system. Harré and van Langenhove's (1999) positioning theory is the primary lens (Wagner & Herbel-Eisenmann, 2009) for examining how Ghanaian elementary teachers position their students in mathematics classroom discourse. McVee (2018) acknowledges that positioning theory (PT) encompasses diverse communicative practices that can be observed in actions and gestures. Therefore, we as educators must recognize that although many theorists concentrate on spoken interactions, Harré and others acknowledge a range of symbolic representations and actions as positioning methods. Consequently, as this study employed Positioning theory, it considered various symbols, not just verbal communication, that could position individuals within or in relation to specific narratives or storylines. Positioning theory highlights how rights and responsibilities are negotiated in interaction and how these negotiations shape participants' roles in shaping individual roles within a given social context. It emphasizes the rights and responsibilities that individuals assume during these interactions. Sociocultural learning theory complements this view by emphasizing learning as mediated through social interaction (Vygotsky, 1978).

Guided by this framework, the study addresses an overarching research question, with two sub-questions:

1. How do Ghanaian elementary teachers position their students as mathematical doers?
    a) What perception do teachers hold about their students' abilities?
    b) How do teachers position students in classroom interactions?

Methods

This qualitative study took place in Winneba, a municipality in the Central Region of Ghana, and involved five (Teachers A, B, C, D, and E) Grade 3 teachers from five different schools, allowing for varied positioning practices. Data were collected through classroom observations, video recordings of lessons, and semi-structured interviews with teachers about their positioning practices and perceived influence of positioning on their instructional moves.

Each teacher was observed across three consecutive mathematics lessons to identify patterns in how they positioned students and the associated participation structures and teaching strategies (Drageset & Ell, 2024). The analytical framework integrated the MIELL Observation Rubric with Wilson et al.'s Seven Forms of Practice. Using positioning theory's constructs—communication acts, positionings, and storylines—I analyzed teachers' interactions with the students (Herbel-Eisenmann et al., 2015). Video data were segmented into 7.5-minute chapters in line with the MIELL Observation Rubric. Within each chapter, instances (Wilson et al., 2019) were documented to determine the frequency of each practice.

Description of the codes of analysis. Wilson et al. (2019) identified the seven forms of practice. They conducted a comparative analysis of teaching practices in two sets of middle-grade mathematics classrooms: Phase 1, where African American students outperformed expectations on standardized assessments, and Phase 2, where they did not. The findings suggest that while all Phase 1 classrooms demonstrated conceptually oriented instruction, several additional teaching practices were more prevalent in these settings compared to the Phase 2 classrooms. The authors argue that these additional practices are important for providing equitable access to high-quality mathematics education. The seven identified teaching practices that correlate with improved mathematics outcomes for marginalized student groups are attending to the classroom community, attending to language, attributing mathematical authority to students, attending to students' local context, coaching students, making expectations explicit, and positioning students as competent. These practices served as the codes used in this study.

The analysis focused on teachers' strategies to foster students' participation and engagement, such as revoicing students' contributions, asking probing questions, providing feedback, clarifying concepts, explicitly validating students' reasoning, elevating students' responses, and opening spaces for students to share their ideas.

Findings

Cross-Case Synthesis of Teachers' Form of Practices Positioning Students as Math Doers in the Observations

This cross-case synthesis of fifteen lessons examines how teachers' enacted positioning practices reflected their perceptions of students' abilities and beliefs about learning. The summary highlights key consistencies, contrasts, and tensions across cases.

Attending to community. All teachers aimed to cultivate a sense of classroom community. Teachers A, C, and D created robust participatory environments through chants, clapping, songs, and shared rituals, positioning students as members of a learning community and fostering belonging. Teacher B combined similar rituals with strict behavioral norms, positioning students as community members within a disciplined environment. Teacher E also used rituals and occasionally encouraged students to validate one another's answers, but discipline tended to override positive community-building. Teacher D went further in constructing group identities and explicitly balancing participation between boys and girls, naming and recognizing groups to support equitable involvement.

Attending to language. All teachers emphasized correct mathematical vocabulary. For Teachers A, B, C, and D, language functioned as a bridge between informal student talk and formal mathematical discourse. Teachers A and C consistently revoiced students' informal expressions into formal terms and provided frequent bilingual scaffolding. Teacher D systematically built vocabulary over time (e.g., from perimeter to time routines and clock-related terms). Teacher B also used bilingual support and revoicing to transition students from familiar to formal language. In contrast, Teacher E treated language as a gatekeeper mechanism, equating precision with mathematical competence and insisting on exact terminology (e.g., "If you don't write the unit, you are wrong").

Attributing mathematical authority. Teachers C and D most clearly decentralized mathematical authority, distributing it across the classroom and positioning students as legitimate validators and correctors. They invited students to validate peers' work, identify and correct errors, and self-correct at the board. Teachers A and B allowed some shared authority, but Teacher B retained strong teacher-centered authority with limited peer validation. Teacher A encouraged students to test, estimate, and propose answers, yet reserved final judgment. Teacher

E most strongly centralized authority: she relied on teacher validation, and peers only affirmed correct answers rather than engaging in shared reasoning.

Attending to local context. Teachers A, C, and D actively positioned students as everyday mathematicians by drawing on local contexts. Teacher A richly incorporated familiar objects (e.g., bowls, bottles, and polytanks). Teacher C strongly anchored lessons in local practices (e.g., farming, routines, local measurements), while Teacher D consistently used everyday situations (e.g., church, TV, meals, wristwatches, phones). Teacher B referenced local contexts such as trading and measurement, but less frequently and less extensively. Teacher E rarely used local context, favoring abstract, decontextualized tasks with limited connections to students' lives.

Coaching and making expectations clear. All teachers made expectations for participation explicit. Teachers A and C framed expectations through coaching and encouragement, treating mistakes as part of learning. Teachers B and E focused on rules and compliance, pairing procedural guidance with discipline. Teacher D integrated expectations into group work, emphasizing neatness, balanced turn-taking, and group norms to promote fair participation.

Positioning students as competent. Teachers A, C, and D defined competence broadly, encompassing effort, reasoning, and improvement, not just correctness. They framed errors as opportunities for learning, avoiding shaming or negative labels, thus positioning students as contributors and sense makers. Teacher B frequently revoiced students' contributions but, like Teacher E, linked competence more narrowly to correctness, neatness, and adherence to rules, with only occasional recognition for improvement.

Overarching storylines. Each teacher's interactional patterns produced a particular storyline about what mathematics is and who counts as a "math doer." Teachers A, C, and D organized their classroom around participation, reasoning, and improvement. For Teacher A, Mathematics was practical and something to reason through together; for Teacher C, mathematics was reasoning in a safe community where errors are opportunities; for Teacher D, mathematics was participatory, shared by everyone, and connected to real life. Teachers B and E reinforced storylines of mathematics as rule-bound, precise, and teacher-controlled, making students' status as "doers" conditional on compliance. For Teacher B, mathematics was fun, but success was ultimately defined by correctness and careful procedural work. For Teacher E, math was procedural and precise, with competence equated almost restrictively with correct answers.

Integrated insight. Taken together, the five cases form a continuum of positioning practices, from inclusive to mixed to restrictive, that shapes participation. In classrooms where community, local relevance, and productive use of errors were (A, C, and D), students were positioned as capable contributors even when their responses were partial or incorrect, or regardless of the correctness. In classrooms where the focus is on discipline, rules, and precision (E), or those that combine engagement and correction with limited reasoning (B), students are seen as competent only when they are correct and compliant.

The cross-case and integrated syntheses reveal a clear pattern in teachers' practices, distributed along a continuum of positioning students as "Math doers." Viewed together, these patterns form a spectrum of positioning practices, from inclusive to mixed to restrictive, which shape classroom participation, engagement, and learning.

Teachers A, C, and D anchor the inclusive end of the spectrum, consistently treating students as competent learners whose contributions, even when approximate, warrant attention and refinement. Teachers B and E lean toward more restrictive positioning, tying competence by correctness and compliance. Teacher B, however, occupies a middle position: his emphasis on discipline and correctness coexists with inclusive practices such as revoicing, building

community through songs, providing enjoyable activities, drawing on local contexts, and using bilingual scaffolding. This mix generates tension; even as his practices invite participation, his recognition of competence remains largely confined to correct responses. Figure 1 illustrates the spectrum of positioning observed in the findings and cross-case analysis.

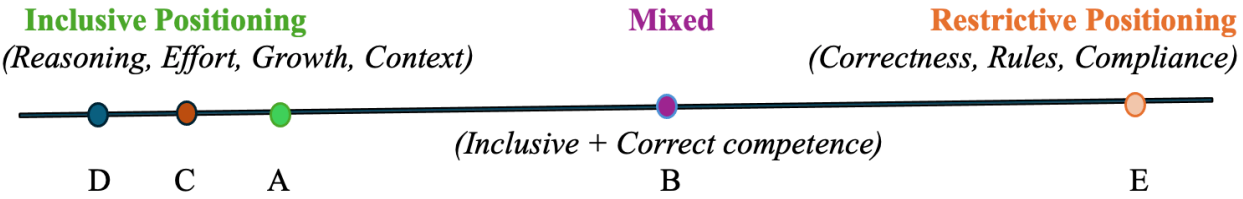

Figure 1: Spectrum of Teacher Positioning

Discussions

Teachers' perceptions about students' abilities. Interview findings showed that teachers generally held positive views of their students' mathematical abilities and expressed confidence in their capacity to learn mathematics, though with notable differences in depth and nuance. Most rated their students as "good" or "very good." For example, Teacher D believed her students could succeed and frequently work independently with minimal explanation, signaling strong trust in their capabilities. In contrast, some teachers framed students' struggles as evidence of limited potential. For instance, Teacher E viewed certain students as unlikely to improve substantially and treated ability as unstable and heavily dependent on teacher-led instruction. This stance reflects Dweck's (2006) concept of a fixed mindset, in which teachers see students' abilities as constrained and any progress as fragile. Such orientations may yield gains in procedural fluency but are unlikely to promote lasting conceptual understanding. Students may perform accurately in familiar contexts yet struggle to adapt to novel problems (Skemp, 1976). Other teachers emphasized emotional and relational aspects. Teacher C highlighted students' emotional sensitivity, demonstrating care for their well-being, while Teacher B described a range of abilities, noting that students were more cooperative and higher achieving. These patterns align with Myers et al. (2013), who found that teachers tend to group students by perceived ability or prior achievement, particularly during professional development on learning trajectories (LTs). Position theory (Harré & van Langenhove, 1999; Herbel-Eisenmann et al., 2015) suggests that perceptions and the roles teachers assign to students shape motivation, self-efficacy, and achievement. Accordingly, teachers' perceptions influence students' skills and participation in mathematics (Wood et al. 2019). Overall, these findings support prior research indicating that teachers' views and practices strongly influence students' engagement and learning (Yamakawa et al., 2009; Turner et al., 2013). The teachers in this study enacted positioning practices that reflected their beliefs about students' abilities and learning, supporting Mosvold and Bjuland's (2019) argument that managing students' positioning is central to effective mathematics instruction.

How teachers position students as math doers. Positioning students as active participants in mathematics is more than praising them or inviting participation. It is a sociocultural process through which teachers signal who is seen as mathematically competent, whose ideas are valued, and who holds mathematical authority (Yamakawa et al., 2009; van Langenhove & Harré, 1994). For the five Ghanaian elementary teachers in this study, positioning practices were shaped by their beliefs, language, instructional choices, storylines, and interpretations of mathematical

learning, in line with Anderson's (2019) mediational approach to positioning theory. Drawing on combined interviews and observation data, the study offers a coherent and nuanced account of how these teachers shape students' identities as mathematical participants. Across cases, positioning was frequently articulated in affective terms, with relational and affective positioning emerging as central to all five teachers' practices.

Across the five cases, Ghanaian elementary teachers positioned students as "math doers" through (a) their discourse patterns (affirming or evaluative), (b) the extent to which they share mathematical authority, (c) the forms of practice they employ (collaborative or procedural), (d) the storylines they construct about the nature of mathematics is, and their beliefs about student capabilities. In summary, Teachers A, C, and D tended to position students as competent sense-makers; Teacher B positioned students as enthusiastic yet dependent learners, and Teacher E positioned students as passive followers of procedures.

Implications of the spectrum. The spectrum illustrates that teacher positioning is not merely rhetorical but is embodied in routine classroom practices, such as daily rituals, scaffolding, error framing, language use, affirming, revoicing, and contextualization. As shown in Figure 1, it helps illuminate how subtle variations in teacher practices shape student participation, demonstrating that positioning is not binary but fluid and context-dependent (Davies & Hunt, 1994). This perspective suggests that teachers may move along the spectrum in response to lesson goals, classroom dynamics, subject matter, or individual student needs. Nonetheless, a teacher's dominant orientation, whether inclusive or restrictive, ultimately shapes students' mathematical identities and opportunities.

Implications for Future Professional Development and Recommendations

Teacher education programs should therefore move beyond a narrow focus on content knowledge and pedagogy to include:

- developing awareness of how teachers' perceptions and beliefs about student ability influence positioning.
- Provide intentional training in inclusive discourse practices.

Making positioning an explicit focus of professional development could support a shift away from primarily corrective practices toward a more expansive recognition and use of student competence.

Additionally, the findings suggest that teachers' everyday instructional decisions, particularly their communication acts, play a significant role in positioning students as either competent or restricted learners. To promote mathematical engagement, teachers should:

- Pose probing, open-ended questions that invite student reasoning.
- Attribute mathematical authority to students by validating and extending their ideas.
- Create space for mistakes and multiple solution strategies.
- Consistently affirm students' responses.

Future research should examine positioning practices among a larger and more diverse sample of teachers and across multiple contexts to clarify how these practices vary and how they might be reshaped to promote more equitable participation and learning in mathematics.

Reading picture books to students can promote joy and curiosity while also supporting them in making meaningful connections to mathematical ideas. In particular, the types of questions asked during interactive mathematics read-alouds can target different levels of mathematical thinking. However, we need a clearer understanding of what happens in practice and what research suggests as effective questioning practices during interactive read-alouds that engage students in making sense of mathematical ideas. For this paper, we conducted a systematic literature review, focusing on detailing how mathematical read-alouds are used. In particular, we focus on a subset of the papers that describe the types of questions asked during interactive mathematics read-alouds. We analyzed 52 papers and found that, beyond detailed questioning categories, teachers also included questions related to mathematical affect.

Keywords: Elementary School Education, Instructional Activities and Practices

One of the National Council of Teachers of Mathematics' key recommendations for catalyzing change includes having students "experience the wonder, joy, and beauty of mathematics" (Huinker et al., 2020, p. 11). Key to this recommendation and other recommendations is to both provide the opportunity for students to wonder and ask questions, as well as for teachers to ask purposeful questions. One type of motivating mathematical exploration that can promote connection to and joy of mathematics is through picture books (e.g., Columba et al., 2009; Hintz & Smith, 2020; van den Heuvel-Panhuizen et al., 2016; van den Heuvel-Panhuizen & van den Boogaard, 2008), which builds on students' joy of listening to stories. The development and design of picture books that explicitly introduce mathematical concepts is a practice that has drawn increasing attention with the creation of the Mathical book awards (MSRI/Simons Laufer Mathematical Sciences Institute, 2026). However, researchers and educators also identify the benefits of mathematizing picture books that are not explicitly mathematical (e.g., *Yard Sale,* Bunting, 2015; see Columba et al., 2009) during interactive read-alouds. Interactive read-alouds are when the teacher stops at key points to invite discussion. Recently, Hintz and Smith (2022) outlined three types of instructional practices that teachers can use to help students notice and wonder, and think more deeply about mathematical ideas embedded in the story's content or illustrations as they listen to picture books read aloud. While important, their focus was on eliciting students' thinking through general questions, such as, "What do you wonder?" As they demonstrate, not only is questioning an important teacher practice in the mathematics classroom and in elementary contexts, but incorporating questioning within picture books during read-alouds is also a common and important practice. However, there are many additional types of questions, beyond asking about notices and wonderings, which may elicit both mathematical and non-mathematical ideas, that teachers might ask during picture book readings to engage students with the story's mathematical ideas.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Torbeyns et al. (2024) identify mathematical questions as those that encourage students to provide responses that relate to different mathematical domains (e.g., number and operations, measurement, geometry, space and location, patterns, etc.). Further, they delineated four levels of abstraction that could occur with mathematical questions posed during picture book reading. At level 1, questions focus on features that are directly perceptible, such as a numeral printed on the page or pointing to where the *inside* of the box is. At level 2, questions go a step further by having children integrate multiple components of the visuals, perhaps including some recall, such as finding the total number of apples on the tree. At level 3, questions require students to use information that is not immediately present, such as combining information with that on a previous page or making judgments based on the story's content or illustrations (e.g., determining the total number of apples across multiple pages). Finally, level 4 questions involve predictions. While there are several accounts of researchers and teachers using questions when reading picture books within mathematics lessons, the field lacks a clear and cohesive understanding of the scope of these questioning practices across the elementary grades. In this brief research report, we take a portion of our systematic literature from an educational database to answer the following research question: What types of questions do teachers and researchers use during interactive mathematics read-alouds with the picture books?

Methods

By using specific search terms in the educational database ERIC (EBSCO), applying inclusion and exclusion criteria on abstracts and titles, and later reviewing the entire papers, we landed on 52 sources that involved interactive mathematics read-alouds (see Figure 1).

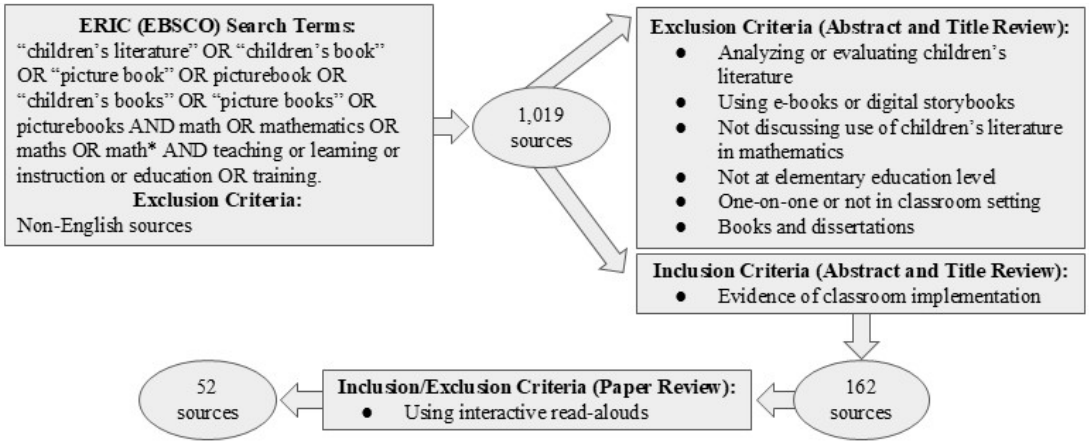

Figure 1: Inclusion and Exclusion Criteria and Results

We focus our analysis on the questions asked during the interactive mathematics read-alouds of these 52 sources. First, we identified whether the questions were non-mathematical or mathematical. Second, we focused on classifying the mathematical questions by content area (e.g., number and operations, measurement, geometry, etc.) and the four levels of abstraction that reflected mathematical questions (Torbeyns et al., 2024). Table 1 provides descriptions and examples from these 52 sources for the mathematical and non-mathematical questions, as well as the four levels of abstraction.

Table 1: Descriptions and Examples of Non-Mathematical Questions and Four Levels of Abstractions for Mathematical Questions

Question Types		Description (Torbeyns et al., 2024)	Example
Non-Mathematical Questions		Questions not related to mathematical ideas in the story.	"What do you notice?" "What do you think the party is for?"
Mathematical Questions: Levels of Abstraction	Level 1	Questions related to salient perceptual information in the text or visuals of a page.	"What number is this?"
	Level 2	Questions related to specific aspects and integration of separate components of salient perceptual information in the text or visuals of a page.	"How many ducklings do you think there are altogether?"
	Level 3	Questions not related to perceptual information in the text or visuals of a page. Instead, they require children to reorder or restructure information from the page or previous pages.	"How many cats are there now? How do you know?"
	Level 4	Questions related to predicting what would happen in the story.	"How many ways could we spend a nickel buying candy marked one cent, two cents, and five cents?"

In the analysis, we found additional question types that did not align with any of the levels of abstraction and mathematical questions that emerged from non-mathematical questions. We discuss these question types in the results below.

Results and Discussion

Of 52 sources, 36 were studies conducted in the United States, and 16 were outside of the United States, with target grade levels ranging from pre-kindergarten to sixth grade. Among these sources, three did not include examples of any questions despite clearly indicating the use of mathematics interactive read-alouds and asking questions in their studies. By far, questions related to number and operations were the most popular across the papers, with at least 22 of them specifying questions asked on these topics. Examples include, "Did the caterpillar eat more strawberries or more oranges?" (Green et al., 2018, p. 10) and "How many ducklings do you think there are all together?" (Burns, 2005, p. 28). Nine others focused primarily on geometry and space related questions, three focused on patterning, and two integrated geometry and measurement topics within perimeter and area questions while one integrated number and measurement topics through time questions. Other papers discussed multiple books, and therefore, the questions spanned multiple subject areas.

Twelve sources shared non-mathematical questions. Some examples of these questions are "Why does Noodle start to sneak away?" (Petronzi et al., 2024, p. 149) and "How did the

caterpillar feel after eating all the food items on Saturday?" (Green et al., 2018, p. 10). Although five of these sources focused exclusively on these non-mathematical questions, in other sources, these questions led to sharing and discussing mathematical questions at different levels of abstraction. For example, in Whitin and Whitin (2006), the teacher started by asking, "What do you notice?" for each picture in the *More, Fewer, Less* book and later guided children by asking, "How many cheeses have orange edges? How many have red edges? Are there more cheeses with orange edges or more with red edges?" (p. 197). These questions reflect levels 1 and 2 of abstraction. Likewise, some of the non-mathematical questions taken out-of-context of a particular classroom may not sound mathematical but within the particular context are interpreted as mathematical. For example, "What kind of questions could we explore about this story?" (Wickett, 1997, p. 476) could be used in a non-mathematical way and is open to that interpretation. However, in the context of the classroom where this question was used, students clearly understood it as referring to mathematics. These results point to the importance of understanding the context in which the questions were asked.

Another interesting result related to non-mathematical questions was sources focusing on other aspects of mathematics rather than content areas. For instance, one paper focused on questions around mathematical anxiety using a book that was designed for a study on supporting mathematical identities. The questions accompanying this book focused on how the character feels about math and why, while also posing questions to the listeners, "Have you ever felt scared about math?" (Petronzi et al. 2024, p. 149). Another paper (Crawford-Mckinney & Özgűn-Koca, 2022) hinted at a similar theme around mathematical anxiety and identity, where the teacher used *When Sophie Can't* and asked, "Why do you know who is 'smart?,'" "What makes them smart?," "Why is the word yet important?" (p. 627). Although these questions do not appear mathematical, they are meant to probe students' thoughts about who is smart at mathematics. Therefore, our results from this systematic literature review provide another category of question type related to mathematical affect.

Regarding the four levels of mathematical questions, we found 12 sources with level 1, 17 with level 2, 21 with level 3, and 13 with level 4 questions. In one researcher-design book aimed at teaching children patterning, the questions align directly with aspects of patterns and patterning across the four levels (Wijns et al., 2023). For example, a level 2 question included "What color streamer do they need to put up next?" (p. 737), which could be determined by looking at the accompanying picture. However, a level 3 question required children to make connections between two similar patterns and how an auditory pattern describing them both would be the same: "Why does the 'beep boop' sound the same when the cake has different colors?" (Wijns et al., 2023, p. 737). Teacher-led book readings also included questions that required students go beyond what was on the page. For example, in one story, a teacher asked a rhetorical question (focusing on numbers and operations) about apples on the page, "This basket has more apples than this basket, doesn't it?" but then later asked, "If we add one more, how many would we have?" (Hojnoski et al., 2016, p. 681). Beyond these levels, questions focused on eliciting students' justifications and reasoning. Overall, the results point to integrating and extending mathematical thinking as important practices in interactive mathematics read-alouds.

AI-GENERATED FEEDBACK AND PRESERVICE TEACHERS' UPTAKE IN MATHEMATICS TEACHING SIMULATION

Hea-Jin Lee
The Ohio State University at Lima
lee.1129@osu.edu

This study examines AI-generated evaluative feedback as a learning tool for supporting preservice teachers' (PSTs) self-assessment and subsequent mathematics teaching practice. Using data from 10 PSTs with complete paired simulations, the analysis compared AI evaluations, PST reflections, and simulation transcripts to identify alignment, unnoticed areas of practice, and evidence of feedback uptake. Findings suggest that AI feedback confirmed PSTs' perceptions of encouragement while drawing attention to questioning, mathematical precision, and checks for understanding. Uptake was uneven: PSTs who explicitly engaged with AI suggestions in reflection were more likely to enact related moves later. The study treats AI evaluation as a useful but incomplete feedback resource that requires human mediation and structured opportunities for uptake.

Keywords: Preservice Teacher Education, Instructional Feedback, Artificial Intelligence

Introduction

Learning to teach mathematics involves more than learning pedagogical strategies. Preservice teachers (PSTs) also need to learn how to interpret their own instructional decisions and decide what to revise. This is difficult work. PSTs may notice whether students seem engaged but miss whether their questions elicit reasoning, whether their language is mathematically precise, or whether their feedback keeps opportunities for sense making open (Santagata & Yeh, 2016; Sleep & Boerst, 2012). Teacher preparation programs therefore need repeated, low-stakes approximations of practice in which PSTs can rehearse instruction and receive feedback specific enough to support revision (Grossman et al., 2009; Zeichner, 2012).

Generative AI simulations offer new possibilities for this kind of rehearsal (Zhang et al., 2026; Zhuang & Zhang, 2025). PSTs can respond to AI-student errors, ask for an evaluation of their instructional feedback, and then compare that evaluation with their own reflection. Yet feedback does not support learning simply because it is immediate. Learners have to interpret it, decide whether it is useful, and use it to guide later action (Boud & Molloy, 2013; Winstone et al., 2017). In teacher education, this distinction matters because AI evaluations may attend closely to visible discourse moves while missing relational, contextual, or equity-oriented dimensions of teaching.

This study examines AI-generated evaluative feedback as a resource for developing PST self-assessment and uptake in mathematics teaching simulations. Two questions guided this study: (1) How does AI feedback align with PSTs' self-assessments, and what aspects of practice does it make visible? (2) To what extent do PSTs incorporate AI feedback into a later simulation, and what patterns distinguish stronger from weaker uptake?

Theoretical Perspective

The study draws on three perspectives. First, research on feedback emphasizes that useful feedback clarifies goals, provides information about current performance, and offers guidance for closing the gap between current and desired practice (Hattie & Timperley, 2007). Boud and Molloy (2013) argue that feedback should be designed as a learner-centered process rather than

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

information transmitted to a passive recipient. This point is important for this study: AI-feedback may be immediate and detailed, but its value depends on how PSTs use it.

Second, self-assessment and reflection are treated as developing forms of professional vision, not simply as introspection. Beginning teachers often focus on surface features of lessons and may not yet recognize the instructional significance of eliciting student reasoning, pressing for explanation, or checking understanding (Lee, 2005; Schön, 1983; Santagata & Yeh, 2016). External feedback can help by making differences visible between how PSTs perceived their teaching practice and what they actually did (enacted practice).

Third, the study draws on work on responsive mathematics teaching. Productive feedback to students involves selecting follow-up moves that advance mathematical thinking rather than simply correcting answers (Jacobs & Empson, 2016; Robertson et al., 2016). For that reason, the analysis focused not only on whether AI evaluations were positive or negative, but also on whether they pointed PSTs toward teachable moves such as asking open questions, using representations, maintaining mathematical precision, and eliciting student explanations.

Methods

Nineteen PSTs enrolled in a mathematics methods course participated in AI-student simulation activities. The analytic sample included 10 PSTs who consented and submitted complete data across two simulations conducted six weeks apart. In each simulation, PSTs interacted with an AI-simulated student around a mathematics task, requested follow-up evaluative feedback, and wrote reflections on their learning and on the AI evaluation experience. The data sources were simulation transcripts, AI-generated evaluations, and written reflections.

For each simulation, the analysis compared three records of practice: what the PST did in the transcript, what the AI evaluation emphasized, and what the PST recognized in reflection. This comparison identified convergent awareness, AI-revealed gaps, PST-identified concerns, and contradictions. Analysis proceeded in two cycles. First, AI evaluations were coded for strengths, improvement suggestions, specificity, and actionability. Second, a cross-case matrix was used to examine alignment and uptake. A Simulation 1 suggestion was coded as taken up when Simulation 2 transcript evidence showed a corresponding instructional move. Given the small sample, percentages are descriptive rather than inferential. Uptake coding was anchored in transcript evidence; for example, a recommendation to ask for reasoning counted only when the second transcript showed the PST inviting explanation or justification. Analytic memos were used to compare discrepant cases, including instances in which PSTs raised affective concerns that AI did not address.

Findings

AI feedback: Confirmed and Extended PST Self-assessment

Across AI-evaluation and PST-reflection pairs, PST reflections and AI evaluations often converged around broad strengths, especially encouragement, patience, and growth-oriented feedback. Nine of ten PSTs recognized that they were supportive, and AI evaluations usually affirmed this perception. PSTs also sometimes recognized when they over-explained rather than elicited student thinking. However, as shown in Table 1, 31% of instances involved AI-revealed gaps, most often related to questioning, precision, and checks for understanding.

AI evaluations were most useful when they connected a general judgment to a specific alternative teaching move. Broad praise rarely added much because PSTs already recognized those strengths. More useful feedback named transcript feature and translated it into a next move: ask for reasoning, pause before introducing a procedure, use a representation, or restate a

rule with place-value language. In these instances, AI feedback worked less like a score and more like a source of possible moves to try.

Table 1: Alignment Between AI Evaluations and PST Self-Assessments

Type	%	Description	Example
Convergent Awareness	62%	PST and AI identify same strengths/weaknesses	PST: "I told too much" AI: "Balance telling with eliciting"
AI-Revealed Gaps	31%	AI identifies issues PST missed	AI: "Use more open questions" PST reflection: no mention of questioning
PST-Identified Concerns	18%	PST recognizes issues AI didn't mention	PST: "worried about making students feel bad" AI: no mention
Contradictions	7%	PST and AI disagree about quality	PST: "explained clearly" AI: "explanations too complex"

Note. Percentages are descriptive and based on 10 PSTs with complete data. Percentages exceed 100 because cases could contain more than one alignment type.

The most frequent AI-revealed gaps were pedagogically consequential. AI recommended more open-ended questions in 45% of evaluations, whereas only 20% of PST reflections named questioning as a growth area. Mathematical precision appeared in 40% of AI evaluations but only 15% of reflections; comprehension checks appeared in 35% of evaluations but 10% of reflections. These patterns suggest that AI feedback can draw attention to features of instructional discourse that novices may not yet notice on their own.

PST self-assessment was not simply inaccurate; it varied by dimension of teaching. PSTs were more accurate when judging tone, encouragement, and whether they had explained a procedure. They were less accurate when judging how their discourse positioned the student as a mathematical thinker. This matters because supportive feedback can still limit learning if it closes down student reasoning.

Uptake: Depended on Explicit Engagement with Feedback

Across PSTs, average uptake was 58%, with variation by individual and suggestion type. Uptake was highest when suggestions were concrete and easy to translate into discourse moves, such as asking students to explain reasoning or using a visual representation. Uptake was lower for mathematical precision, which may require stronger content-specific knowledge and more deliberate rehearsal.

Table 2: Uptake of AI Suggestions by Type in Simulation 2

AI Suggestion Type	Uptake Rate	Evidence of Subsequent Uptake
Open-ended questioning	70%	"Can you tell me why we need the denominators to match?"
Visual representations	65%	"Let's try and draw a picture to see if that helps us"
Checks for understanding	60%	"Does this clear up your questions?"
Balance telling/eliciting	55%	Shifted from direct explanation to guided questions
Mathematical precision	45%	Limited evidence of sustained implementation

Uptake did not always mean better (or improved) mathematical interaction. Some PSTs adopted the surface form of a suggestion, such as asking whether the student understood, without consistently eliciting mathematical reasoning. Stronger uptake involved more diagnostic prompts, such as asking why denominators must match or using a representation to support explanation. Teacher educators therefore need to help PSTs move from simply following a suggestion to understanding instructional purpose behind it.

PSTs who explicitly referenced AI feedback in reflection (n = 6) showed higher descriptive uptake (M = 72%) than those who did not (n = 4, M = 38%). For example, PST RK named two AI suggestion - asking the student to explain reasoning and using visual or concrete models—and then enacted both moves in the second simulation. In contrast, PSTs who wrote general reflections without naming specific suggestions tended to show little change. Thus, AI evaluation alone appeared insufficient; structured reflection helped turn feedback into instructional action.

PSTs Valued Immediacy and Specificity but Recognized Limits

Eight of ten PSTs described the AI evaluation as helpful because it gave immediate, specific comments connected to their own conversation. Several were surprised when AI noticed missed comprehension checks or limited questioning, which supports the interpretation that AI feedback revealed real blind spots. At the same time, two PSTs questioned whether AI could judge teaching because teaching involves relationships, classroom context, and emotional responsiveness. AI feedback was most convincing when it addressed textual evidence of instructional moves and least convincing when judged relational dimensions of teaching.

PST trust in AI feedback was conditional. PSTs were more willing to accept evaluations that matched course language about eliciting student thinking, using representations, and checking understanding. They were more skeptical when AI judged relational quality without broader context. This kind of conditional trust is useful: instructors can treat AI evaluations as texts to examine alongside transcripts and course frameworks rather than as final judgements.

Discussion and Implications

The findings contribute to practice-based teacher education by showing how AI-generated evaluation may support self-assessment within repeated approximations of mathematics teaching. First, AI feedback drew attention to discourse moves that PSTs often overlooked, especially questioning, precision, and comprehension checks. These moves matter because they shape whether feedback only corrects an answer or also advances student reasoning (Jacobs & Empson, 2016; Sleep & Boerst, 2012).

Second, the study underscores the importance of uptake. PSTs who explicitly processed AI feedback were more likely to enact related moves later, aligning with Winstone et al.'s (2017) argument that learners need opportunities to engage agentically with feedback. In methods courses, AI evaluation should be paired with routines in which PSTs select one high-leverage suggestion, locate transcript evidence, plan a revised move, and rehearse it. Such routines preserve AI feedback's immediacy while keeping teacher educators responsible for quality, equity, and mathematical substance.

Third, AI should be a supplementary feedback resource rather than an authoritative judge. Teacher educators remain necessary for interpreting AI suggestions, linking them to course goals, attending to relationships and equity, and helping PSTs recognize incomplete or misaligned evaluations. Although limited by a small sample, single context, and descriptive design, the study suggests that AI-generated evaluation can be productive when embedded in routines that emphasize reflection, evidence, and deliberate uptake.

EXAMINING RELATIONSHIPS BETWEEN THE FIVE PRACTICES AND CLASSROOM DISCOURSE LEVELS IN ELEMENTARY MATH CLASSROOMS

Susie Morrissey
Mercer University
morrissey_gs@mercer.edu

Ozgul Kartal
University of Wisconsin Whitewater
kartalo@uww.edu

Elementary teachers focused on mathematics instruction in a sequence of three eight-week courses, with data from the first two courses included in this preliminary analysis. During each course, part of their assignments consisted of creating a task to implement, using the Five Practices (Smith & Stein, 2018) as a guide. Following task implementation, teachers completed a self-assessment of their classroom discourse and a reflection on the task implementation. These submissions were analyzed qualitatively to determine the teachers' assessment of their expertise in using the Five Practices and the relationship to classroom discourse. Findings showed that as teachers increase their fidelity in the Five Practices, particularly the transition from monitoring work to connecting student ideas, the discourse levels in the classroom increased accordingly.

Keywords: Classroom Discourse, Elementary School Education, Instructional Activities and Practices

The Five Practices, introduced by Smith and Stein (2018), consist of the preliminary practice of setting a goal and selecting a task, followed by anticipating student responses, monitoring student work, selecting, sequencing, and connecting student solutions. While each of these activities is important on its own, the intentional linking of all Five Practices has been seen to improve classroom discourse and student learning. The Five Practices provide a guide for teachers to use to improve their enactment of student-centered classroom discourse (Stein et al., 2008). However, implementing a task using Five Practices with fidelity is challenging for many teachers. This research examined the extent to which the intentional implementation of Five Practices was related to student-centered classroom discourse as measured by Hufford-Ackles et al.'s (2014) mathematical discourse rubric.

Literature Review

Stein et al (2008) presented the Five Practices as a pedagogical model intended to support student discussion while making the process manageable for teachers. Although classrooms at the time exhibited presentations of student solutions, researchers found that simply making ideas public does not engender the same results as eliciting student explanations with probing questions (e.g., Mueller et al., 2014). Stein et al. therefore recommended the Five Practices as "teaching practices that take students' ideas as the launching point, but shape class discussions so that over time important mathematical ideas are surfaced, contradictions exposed, and understandings developed or consolidated" (p. 327). The Five Practices support equity by "revoicing student work in the whole class environment, juxtaposing standard approaches with nonstandard strategies, positioning mistakes as areas to grow, elevating the status of nonparticipators, and allowing students to amplify another student's work in light of new information." (Nabb, 2022, p. 300). Rupe and Borowski (2022) recommended the Five Practices as essential for pre-service teachers, in order to gain experience teaching student-centered mathematics, especially focusing on making connections between representations.

The Five Practices depend on setting goals and selecting tasks. According to the National Council of Teachers of Mathematics (NCTM) (2014), goals must clearly state the mathematics

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

students are to understand, as they guide decision making during lessons. Goals should focus on what students will learn, rather than on the actions students will perform (Smith et al., 2020). Tasks that require high-level cognitive demand are recommended, as research has shown that high cognitive demand tasks lead to improvement in solving complex problems as well as increased student motivation (Ni et al., 2018). Anticipating student responses includes not only anticipating different solution pathways students may take, but also planning assessing and advancing questions, as well as thinking ahead about what aspects of work should be noticed while students are working (Smith et al., 2020). When goals are procedure-based rather than learning-based, anticipated solutions are more likely to focus on procedural errors without considering the underlying gaps in conceptual understanding (Kartal et al., 2020; Morrissey et al., 2019), as goals drive the problem representation, launch, and anticipated solutions (Vale et al., 2019).

The quality of questions planned is important, as these questions will be asked during the practice of monitoring student work. Developing strong questioning skills is an important component of pre-service teacher education, considering that Wimer et al. (2001) and Boaler and Brodie (2004) found many teachers ask mostly fact-gathering questions. Teachers' reasoning for selecting and sequencing solutions varies. Teachers may select the solution of a student who is comfortable sharing, or select a correct solution of a student who needs to build confidence (Dunning, 2023; Kersaint, 2017). Alternatively, teachers may show different representations or procedures in order to build up to an efficient procedure or to expose misconceptions (Dunning, 2023; Kersaint, 2017; Meikle, 2016). Meikle (2016) further noted that regardless of the method used for selecting and sequencing solutions, it is vitally important to connect solutions.

According to NCTM (2014), "Effective teaching of mathematics facilitates discourse among students to build shared understanding of mathematical ideas by analyzing and comparing student approaches and arguments" (p. 29). Classroom discourse around different solutions and their connections is intended to advance the conceptual understanding of the whole class. To achieve this, the Five Practices (Stein et al., 2008) provide a roadmap for teachers to orchestrate discussions where students share ideas, justify their reasoning, and make connections between solutions (NCTM, 2014). The successful implementation of these practices serves as a vehicle for moving a classroom along a developmental framework defined by Hufford-Ackles et al. (2014). This framework describes levels of discourse across five domains: teacher role, questioning, explaining mathematical thinking, mathematical representations, and responsibility for learning. As a classroom moves from Level 0 to Level 3 on those domains, the teacher shifts from being the sole authority to a facilitator.

Given that the ultimate goal of the Five Practices is to create effective classroom discourse, this study investigated "how does teachers' implementation of the Five Practices relate to the level of classroom discourse?"

Methods

Teachers at a Southeastern University enrolled in a three-course sequence of eight-week advanced mathematics methods of teaching were assigned to teach a task using the Five Practices during each of the eight-week courses, with the goal of improving their fidelity of implementation and improving their classroom discourse over the three courses. Seven teachers participated in the study, one Latino male and six females (two White and four Black), with a range of teaching experience from one to eight years. Data collected in this study were from the first two of the three-course sequence.

In the first course, prior to the Five Practices assignment, teachers read and discussed Smith and Stein's (2018) book on the Five Practices, along with an NCTM publication (NCTM, 2014), an article about transforming mathematics education (Green, 2014), and the *Launch, Explore, Discuss Lesson Framework* (North Carolina Collaborative for Mathematics Learning, 2017). Teachers then engaged in the Five Practices assignment along with reading and discussing selections from 2 textbooks (Van de Walle et al., 2018a; Van de Walle et al., 2018b), an article related to the Five Practices (Meikle, 2016), and an article on equity (Thomas et al., 2024). In the second course, teachers read and discussed additional articles related to equity (Gallivan, 2020; Roberts et al., 2022; Schmidt et al., 2022; Wilson & Smith, 2022; Yeh et al., 2020), as well as pedagogy (Boaler et al., 2021; Candela et al., 2020).

For the Five Practices assignment, teachers designed or selected a high-cognitive demand task that allowed multiple entry points, required students to provide justification or explanation, connect diverse representations, engage in student-student discourse and identify mathematical patterns to make conjectures and/or form generalizations. These tasks were discussed with classmates to gather feedback and ideas for improvement. Teachers then created anticipated solutions and planned assessing and advancing questions for each solution. The course instructor (one of the authors) also provided feedback on tasks, anticipated solutions, and planned questions. Teachers used a monitoring chart to monitor which students provided each of the anticipated solutions (as well as other, unanticipated solutions), and decided in what order to present the solutions to the class. Finally, teachers implemented the task, video-recorded the lesson, wrote a reflection on the implementation, and self-assessed the classroom discourse while reviewing the video. Teacher reflections and discourse self-assessments from each of the first two courses were collected and analyzed.

Instruments

In each course, after implementation of the task, teachers completed a reflection, detailing how the experience of task implementation was different from their previous instruction, for both themselves and their students. Teachers then used the *Levels of Discourse Rubric* (Hufford-Ackles et al., 2014) to assess classroom discourse, and commented on shifts in their practice specifically related to the Rubric. Finally, teachers reflected on how to refine their practice moving forward. The *Levels of Discourse Rubric* moves from Level 0 to Level 3 as teaching moves towards more student-centered discourse in the areas of Teacher Role, Questioning, Explaining Mathematical Thinking, Mathematical Representations, and Building Student Responsibility within the community.

Data Analysis

To analyze the relationship between the Five Practices and Classroom Discourse levels, first, we used a qualitative deductive content analysis on the teachers' written reflections from the two courses. We coded each reflection for the Five Practices (Anticipating, Monitoring, Selecting, Sequencing, and Connecting) using three levels as Weak (minimal or no evidence), Moderate (theoretical mention or partial enactment), and Strong (clear, evidence-based execution). For example, a teacher wrote "I carried around my question cards and my progress monitoring sheet to help support my students and my own teaching practice" which is evidence that monitoring was purposeful and tied to instructional decisions, not just observation, and hence coded as "strong." Another teacher wrote "I selected my sequence based on the most concrete examples to most abstract" and "I selected her to go first based on my sequencing plan" which was coded as "strong" for Sequencing practice. This coding focused on the depth of teacher reporting rather

than just the presence of a practice. Second, we aligned the implementation strength of the Five Practices with teachers' self-assessed discourse levels (0–4).

Findings

Given the small sample size ($N = 7$), statistical tests were not appropriate as they lack the necessary power to generalize findings; instead, we described patterns. Teacher reflections revealed a distinct hierarchy in the implementation of the Five Practices. Teachers generally excelled in the active, "in-the-moment" phase of monitoring ($M = 2.79$) but struggled with the high-level orchestration required for sequencing ($M = 1.36$) and selecting ($M = 1.79$) across both iterations. Reflections often showed that while teachers noticed interesting student work (Monitoring), they lacked a strategic plan for which students should share (Selecting) and in what order (Sequencing) to build a mathematical argument, and many defaulted to having everyone share on the carpet. Teachers were at the "moderate" level on anticipating ($M = 2.00$) and Connecting ($M = 2.14$).

The discourse rubric data showed a cohort transitioning from Level 1 (Teacher-Led) toward Level 2 (Shared Responsibility). Teacher Role, Questioning, and Explaining Math Thinking all shared a mean of 1.71. This indicates that teachers have successfully moved away from traditional lecturing and are consistently asking "Why?" and "How?" to prompt student justification. Math Representations ($M = 1.43$) and Student Responsibility ($M = 1.50$) were the lowest-scored domains. Teachers noted in their reflections that while they are asking better questions, students are not yet independently connecting different representations or taking full ownership of the mathematical authority in the room.

When looking at the numerical relationship between specific practices and the overall discourse level, distinct patterns emerge: There is a strong association between a teacher's ability to "Connect" and the quality of classroom discourse. Teachers who excelled at asking students to build on each other's ideas achieved the highest discourse levels. This suggests that "Connecting" is the bridge that moves a classroom from teacher-led to student-driven. Effective monitoring showed a moderate-to-strong association with discourse levels. This confirms that a teacher's ability to "hear" student thinking in real-time is a prerequisite for facilitating a high-level discussion. Sequencing and Anticipating practices were less directly associated with the real-time discourse scores. This implies that a teacher may have a strong plan (Anticipating), but if they cannot execute the "Connecting" moves during the lesson, the discourse level remains capped.

Overall, the findings suggest that as teachers increase their fidelity in these instructional moves, particularly the transition from monitoring work to connecting student ideas, the discourse levels in the classroom increase accordingly.

Discussion

Important findings to note include the connection between teachers' struggles with selecting and sequencing, and students' inability to independently connect different representations. As teachers improve their fidelity in the "later" practices (Selecting, Sequencing, Connecting), the responsibility for learning shifts from the teacher to the students. This finding aligns with Meikle's (2016) belief that it is vitally important to connect solutions. Because connecting representations is vital to a complete understanding of mathematical reasoning, the selecting and sequencing skills need to be further developed in teachers. Teachers need to understand that sequencing should build on previous solutions and focus on the meanings and relationships between the solutions (Smith & Stein, 2018). It was also noted that, when a teacher is able to

successfully guide their students to connect their solutions to the solutions of others, classroom discourse is improved, resulting in a move towards student-driven classrooms. This finding lends further weight to the importance of connecting representations.

Mathematics education scholars have been promoting instructional reforms for decades, but it is important to consider the extent to which these efforts have yielded changes in mathematics classrooms. Having completed three lesson observations per year of 36 algebra teachers in the Midwestern United States (Study 1) and of 54 algebra teachers across multiple regions of the United States (Study 2), this brief report summarizes general features of the observed instruction. Findings include a consistent instructional pattern characterized by teacher-led and procedurally-focused whole-class instruction and student tasks that are 93% low cognitive demand. Implications are discussed with regard to how these patterns in algebra instruction might form a basis for incremental rather than transformational instructional change.

Keywords: Instructional Activities and Practices, Classroom Discourse, Algebra and Algebraic Thinking

For decades, mathematics education scholars have promoted a "reform-oriented" vision for mathematics classrooms (e.g., Lott et al., 2010; National Council of Teachers of Mathematics, 1980, 1989, 2000, 2014). The accompanying professional development (PD) efforts with teachers have sought to transform instruction away from conventional or "traditional" patterns of classroom teaching (e.g., teacher-led lecture and an emphasis on procedures) and toward a complex but relatively unified alternative form of teaching. Sztajn et al. (2017) pointed to this unified aim in their broad review of PD literature, stating "the majority of [PD studies] embraced a similar vision of [reform-oriented] K–12 mathematics instruction … designed to support teachers in implementing instruction that builds on rich mathematical tasks, attends to student thinking, values interactions as a learning mechanism, and is considered 'ambitious' (Lampert et al., 2010) in its goal of advancing mathematical understanding for all students" (p. 796).

To what extent has mathematics education, as a field, had success in these efforts? If, say, one were to visit mathematics classrooms across the United States, would one observe rich tasks, visible student thinking, learning through robust interactions, and an emphasis on understanding over rote procedure? There have been "pockets of success" (Arbaugh, 2025) regarding the implementation of reform instruction, yet our decades of work in mathematics PD led us to wonder about the prevalence of those pockets. This wondering led us to examine baseline data from two of our large-scale studies to look broadly at the type of mathematics instruction that was occurring when we "first walked in," so to speak. The summaries presented in this brief report depict general aspects of instruction in algebra from 36 teachers in the Midwest United States (Study 1) and 54 teachers from across the entire United States (Study 2). Although not

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

indicative of instruction in other grades or courses, Algebra 1 is an important culmination of middle school mathematics and the launchpad for high school mathematics, and, as is shown below, conventional instruction seems firmly entrenched within this linchpin course.

Background Literature and Theoretical Perspective

Space restrictions do not allow a full treatment of instructional history in North America, but it suffices to say that conventional mathematics instruction, characterized by a teacher defining terms and demonstrating procedures so students may memorize those terms and execute those procedures, has been dominant for more than a century (Karp & Schubring, 2014; Stanic & Kilpatrick, 2003; Stigler & Hiebert, 1999). Various efforts to transform instruction were met with significant resistance (Davis, 2003; Schoenfeld, 2007; Wilson, 2003), and none of the reforms had achieved widespread adoption even before the backlash. More recent instructional change efforts have involved a New Mexican School curriculum reform (Nava-Guzmán et al., 2025), with similarities to NCTM's standards-based reform, as well as many PD efforts focused on specific elements of the reform vision, such as cognitively-demanding tasks (e.g., Boston & Smith, 2009), noticing and building on students' thinking (e.g., Jacobs et al., 2024), student collaboration (e.g., Tabach & Schwarz, 2018) and mathematical discourse (e.g., Herbel-Eisenmann et al., 2013; Staples & Colonis, 2007), or teachers' content knowledge and the development of conceptual understanding (e.g., Garet et al., 2016). But PD success remains difficult to achieve in these areas (Ahl et al., 2023), and even if a pocket of success is achieved, the question remains of how likely it is for the instructional reforms to spread (Otten et al., 2025).

In this brief report we sought to view instruction holistically with an eye toward the extent to which some key features of reform instruction were present. Both studies reported herein viewed students' mathematical learning as a sociocultural process whereby they come to participate actively in a mathematical community (Vygotsky, 1978) and thus learning occurs through and is defined by students' participation in forms of mathematical discourse (Lemke, 1990). For these reasons, the lesson observation protocol (Otten et al., 2021) identifies various activity structures such as whole-class discourse, independent work time, group work time, and non-instructional time. The protocol also attends to holistic aspects within those structures, as described below, as well as the cognitive demand of tasks posed to students (Stein et al., 1996).

The following research questions about the broad features of the algebra instruction observed within two large-scale studies guided this study:

1. How is class time allotted for the activity structures of whole-class discourse, independent work, group work, and non-instructional time?
2. Within whole-class instruction, to what extent are key features of reform instruction present?
3. Within independent or group work, what were the levels of cognitive demand of the tasks assigned to students?

Methods

Classroom data for Study 1 comes from the 2018–19 and 2019–20 school years in two Midwestern U.S. states (36 teachers; 108 lessons). Classroom data for Study 2 comes from the 2022–23 and 2023–24 school years across 14 states in various regions of the United States (54 teachers; 162 lessons). Details can be found in de Araujo et al. (2017) and Otten et al. (2025), respectively. Both studies involved Algebra 1 (or equivalent) classes in Grade 8 and Grade 9, with some Grade 7 and Grade 10 students (ages approx. 11–14). The participating teachers were not necessarily representative of the general population (i.e., they were willing to join a

university-based project and so may be more amenable to university-promoted forms of instruction than are teachers who declined to participate) but the school districts were purposefully chosen in both studies to vary by locale (rural, suburban, urban) and student demographics (race or ethnicity, socioeconomic status) in ways that roughly follow state or national characteristics.

In Study 1, no intervention was performed with the teachers; they were asked to teach in their normal manner for all observations. It should be noted, however, that half of the teachers in Study 1 were implementing flipped instruction (i.e., videos assigned as homework) (de Araujo et al., 2017) and so their use of class time is likely not representative of other algebra teachers. The other half of teachers in Study 1 were in school contexts that matched the first half but they were not implementing flipped instruction. In Study 2, a PD intervention occurred in subsequent years but data reported here were from each teacher's baseline year, prior to any intervention. Teachers in Study 2 were recruited because they were teaching Algebra 1, regardless of instructional style.

In both studies, our research teams conducted at least 3 lesson observations per school year. When more than 3 observations occurred, we randomly selected 3 for inclusion in the present summary analysis. Observations were carried out in person for Study 1 and via video recordings for Study 2, with a process check that the two modalities remain comparable (Wonsavage et al., 2024). All class materials were also gathered from the teachers. Each observation was done by at least two trained research team members, filling out the protocol (Otten et al., 2021) separately and then meeting to reconcile discrepancies. Lesson segments were parsed to the nearest minute and instructional features, described below, were rated on a 3-point scale based on categories, not levels (and 0 was included for features that could be absent).

Findings

Use of Class Time in Algebra Lessons

The most common lesson segments we observed were whole-class discourse (all students expected to attend to shared public discourse) and independent work time (students expected to be working either individually or in voluntary groups but collaboration is not required). Whole-class discourse (WCD) was observed in 92.1% percentage of lessons, averaging 27 minutes out of a typical lesson duration of 57 minutes (47%) across the entire data sets. Independent work time (IND) was observed in 93.2% of lessons, averaging 21 minutes out of 57 (37%). In contrast, group work (GRP), when students were expected to work collaboratively, was observed in just 31.6% of lessons, with an average duration of only 5 minutes (9%) across the entire data sets, or an average of 17 minutes (30% of class time) in those few lessons where GRP occurred.

Table 1: Mean Durations in Minutes of Various Activity Structures in Algebra Lessons (With Median Durations Indicated in Parentheses)

	Class Period Duration	Whole-Class Discourse	Independent Work	Group Work	Non-Instructional
Study 1 (n = 108)	55 (50)	22 (23)	22 (19)	4 (0)	7 (5)
Study 2 (n = 162)	60 (54)	30 (30)	19 (17)	6 (0)	4 (3)
Combined (n = 270)	58 (51)	27 (27)	21 (18)	5 (0)	5 (4)

With regard to class duration, 102 minutes was the maximum observed and 27 minutes was the minimum, with a standard deviation of 16 minutes. The class periods tended to be broken into nine separate segments, with a standard deviation of four segments.

Instruction During Whole-Class Discourse

The observation protocol distinguishes between mathematical authority (choosing the problems to work on, validating correctness, etc.) that lies predominantly with the teacher or textbook (coded as 1) or that is shared among the classroom community (coded as 3). As depicted in Figure 1, the average algebra lesson we observed was 1.1 (SD = 0.3), indicating that nearly all lessons were teacher/textbook authority. The nature of the discourse (Staples & Colonis, 2007), either sharing (univocal with speakers & listeners attempting to receive meaning, coded as 1) or collaborative (dialogic with interlocutors building meaning together, coded as 3) was even more consistent, averaging 1.0 on the scale (SD = 0.2). Although the discourse was univocal, a majority of students tended to contribute at some point to the WCD (mean = 2.3, SD = 0.7), though lessons varied substantially and students' contributions tended to be short (e.g., one-word responses). The development of mathematical ideas was much more often procedural than conceptual (Hiebert & Lefevre, 1986), averaging 1.3 toward the procedural end (SD = 0.6). Only 4% of observed lessons had a predominantly conceptual emphasis. Mathematical representations (equations, tables, graphs, words, etc.) could be solo or only presented in isolation (coded 1) or they could be strongly integrated (coded 3); the average was 1.3 but there was more variation for this characteristic than the others (SD = 1.1).

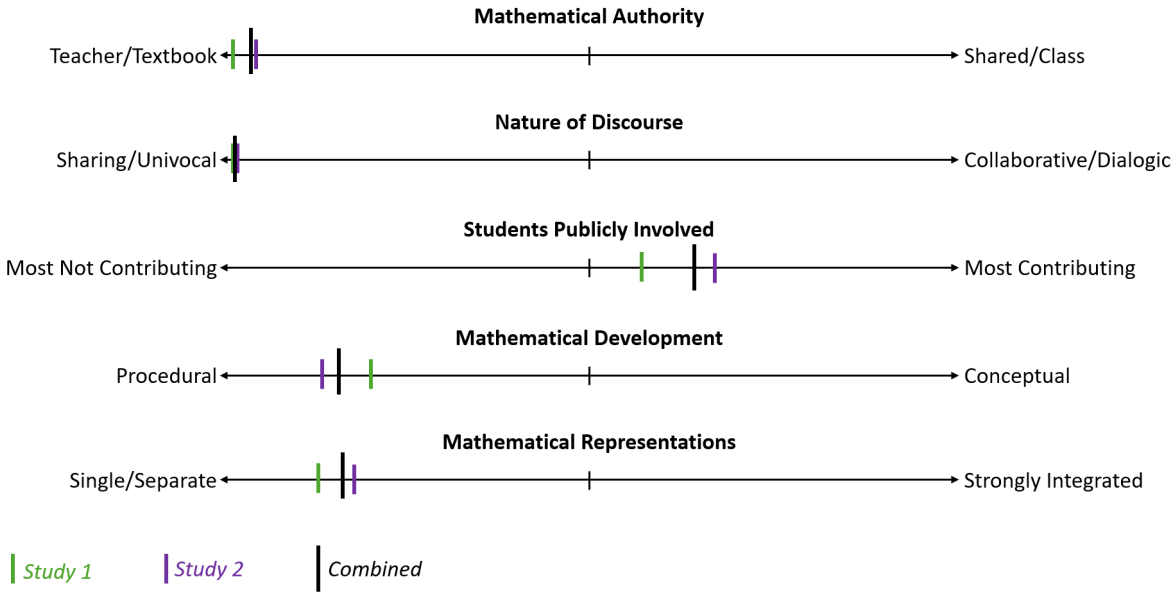

Figure 1: Average (Mean) Characteristics of Whole-Class Instruction in Algebra 1 Lessons

Tasks Implemented During Student Work Time

We previously reported on Study 1 results in Otten et al. (2024), categorizing tasks by level of cognitive demand (Stein et al., 1996). Of those 2,378 mathematical tasks (16.8 per lesson), 2,208 (92.9%) were low cognitive demand involving either *memorization* or the application of *procedures without connection to meaning*. Approximately 6% of tasks were *procedures with connections to meaning* and 0% were *doing mathematics*. Study 2 corroborates those findings: out of 1,695 tasks (10.5 per lesson), 1,577 (93%) were low cognitive demand and only 118 (7%) were cognitively demanding. Only 10 tasks (0.6%) were doing mathematics. Note these tasks were coded as written; they may (and often did) decline in cognitive demand during enactment.

Discussion

Overall, we found many aspects of conventional instruction to be prevalent in algebra classrooms, particularly teacher-led instruction with an overwhelming focus on procedures and low-cognitive-demand tasks. Collaboration was allowed but not typically expected. The key features of reform instruction as described in the introduction were extremely rare. We do not report this as an indictment of mathematics teachers. They are working hard and supporting students within conventional contexts. We share this as a potential reality check for those in mathematics education who, like us, are curious about the extent to which visions of reform instruction have become a reality. At least based on what we have seen, it is not a reality in algebra classrooms in the United States. These findings might provoke reflection upon transformational approaches to PD and instructional change or whether incremental approaches that build directly upon patterns of conventional instruction might be worthwhile (Otten et al., 2025).

Acknowledgments

PROMOTING EXPECTANCY VALUE IN AN EXPERIMENTAL BUSINESS CALCULUS CLASS

PROMOTION DE L'ATTENTE-VALEUR DANS UN COURS EXPERIMENTAL DE CALCULUS POUR LES SCIENCES DE GESTION

William Zahner
San Diego State University
bzahner@sdsu.edu

Abel Sekone
San Diego State University
asekone4584@sdsu.edu

In this brief report we demonstrate how a redesigned Business Calculus course sought to promote students' expectancy and utility value. Grounded in Expectancy–Value Theory, we analyze students' responses to an assignment in which students interviewed professionals in their intended careers about their use of mathematics. Data include 100 written reports collected across two semesters. Using two-cycle qualitative coding, we identified themes related to expectancy (e.g., increased confidence, mentoring) and utility (e.g., use of spreadsheets, basic quantitative reasoning). While few professionals reported direct use of calculus, most described frequent use of spreadsheets and financial calculations, some of which were rooted in calculus. These findings suggest that structured relevance interventions in the context of an ongoing redesign effort can shape students' perceptions of the usefulness of calculus for business majors.

Keywords: Calculus, Undergraduate Education, Design Experiments, Expectancy-Value Theory

Business Calculus is often taught as a terminal course with few prerequisites (May & Bart, 2024; May et al., 2020). Multiple researchers have identified a lack of alignment between the content and pedagogy of Business Calculus and the mathematics found in business and economics (Dahma et al., 2022; May et al., 2020; Spencer-Tyree et al., 2024). This misalignment is an issue in other client-discipline calculus courses, and these issues have inspired interventions in introductory math courses.

At our institution, Business Calculus is usually taught as a large lecture. The DFW rate from 2022-2024 was 28%. Leveraging an institutional grant focused on increasing student success, we created an experimental section of Business Calculus designed to address (a) students' varied preparation, (b) low student engagement during lecture, and (c) the perceived lack of relevance of course content. In prior works we have presented data on student preparation and outcomes and student engagement (Zahner & Sekone, 2025, 2026). In this Brief Report, we delve into the issue of relevance by analyzing student responses to a utility value assignment. Our research question is How do students in an innovative Business Calculus class describe the meaning and use of calculus in their subsequent business courses and envisioned careers?

Theoretical Perspective and Prior Research

Our course redesign drew on the pillars of inquiry-based mathematics education (Laursen & Rasmussen, 2019). For this analysis we focus on an intervention that was rooted in Expectancy Value Theory (EVT). EVT incorporates self-efficacy (expectancy) and perceived utility value. Motivation theorists have documented a positive relationship between expectancy and student success within a domain (Wigfield & Eccles, 2000), as well as a positive relationship between students' perceptions of utility value and success (Hulleman et al., 2010). In other words, theorists in this tradition supported that an individual's beliefs about how well they will do on an activity (expectancy) and the extent to which they value the activity influence their choice,

persistence, and performance. In relation to mathematics, expectancy for success refers to a person's beliefs about their ability to perform well on upcoming mathematics related tasks, either in the immediate or longer-term future (Wigfield & Eccles, 2000). The achievement values portion of EVT include components such as intrinsic value and utility value (Eccles et al., 1983). Intrinsic value is about the enjoyment one gains from doing the task, and utility value or usefulness of the task refers to how a task fits into an individual's future plans, for instance, taking a math class to fulfill a STEM degree requirement and/or to learn skills that will be useful later in one's career. Interventions targeting expectancy value have shown positive results in undergraduate STEM (e.g., Asher et al., 2023; Hulleman et al., 2010; Rozek et al., 2017). For instance, Hulleman et al. (2010) demonstrated that students in the relevance condition, who completed a written task on the utility value of a mathematics activity to their life, were more interested in the mathematics activity at the end of the session than those in the control condition.

As described in more detail below, for this work we asked business students to identify a working professional in their envisioned future career and then interview that person to learn how that professional uses mathematics in their work. This assignment is a twist on the more typical "mathematical autobiography" assignment that is often found in, for example, courses for prospective teachers (Towers et al., 2017). While we anticipated this assignment might increase EVT, we also noted there was some risk: recent research has called into question the utility of (school) mathematics in the workplace (Walkington et al., 2025). Thus, we were not sure whether the EVT intervention would have the desired effect.

Research Methods

Context and Data Sources

We taught the redesigned Business Calculus in a classroom amenable to active learning. In place of the standard textbook, we adopted an open educational resource textbook that used business applications and Excel spreadsheets to introduce each topic (May & Bart, 2024). The course reform was structured as a design experiment, with iterative cycles of implementation and revision (see Brown, 1992; Cobb et al., 2003). The enrollment in the innovative sections was 68 in fall 2024 and 72 in Fall 2025. By way of contrast, each section of the traditional lecture class had a capacity of 300. Given the number of students and repeaters, and the fact that Business Calculus was a required pre-major class, all sections were usually filled each semester.

To document the impact of the intervention, we collected multiple sources of data including student surveys, interviews, and responses to course assignments focused on expectancy value. We also tracked student outcome data such as DFW rates. For this Brief Report we focus on one of the expectancy value interventions, called the "Math in your Major" assignment.

Table 1: Overview of Interviewees' Career Categories

Career Categories	Fall 2024	Fall 2025
Finance, Accounting, and Banking	10	12
Marketing and Sales	9	7
Business Owner / Entrepreneur	9	7
Retail and Operations Management	7	9
Technical and Specialized (e.g. professor of economics)	6	9

Data Collection

Here we analyze 100 submissions representing 85 unique individuals who were interviewed. Table 1 shows the broad categories of careers of interviewees. The student-written reports provided another perspective on the usefulness of calculus for business careers. In accordance with our institution's guidelines for research on student work produced as part of a class, all analysis for the purpose of this research was done after student grades were submitted.

Analysis

We used a two-cycle coding process drawing on the qualitative methods in Miles et al. (Miles et al., 2014). In the first cycle, we re-read the papers students submitted and we used open, descriptive coding focused on statements in the student write-ups related to the expectancy and utility value of mathematics for business. For example, one student wrote that a winery owner "uses spreadsheets to calculate how much the [gift] baskets cost in order to calculate the price to get the best profit margin for the shipment." We coded this excerpt with a descriptive code "Budgeting and Financial Calculations" since the use of mathematics was for budgeting. In the second cycle of coding, we organized the open codes into categories. The first author (W. Z.) did the majority of the first pass coding, and both authors reviewed the coded segments and categories. In a final step we organized the clustered codes to identify six major themes from this assignment.

Results

Table 2 provides a summary of the results of the coding process. We divided the themes according to the two superordinate categories of Expectancy and Utility. The numbers in Table 2 correspond to the count of interview write ups that included at least one code from each theme area. Some documents addressed multiple themes so the sum is greater than 100.

In the category of expectancy, we identified two major themes: Motivation/Self Esteem and Networking/Mentoring. One illustration of the Motivation/Self Esteem theme was found in the account of a student who interviewed an accountant at a poultry farm in his hometown in rural California. Talking to the accountant raised the student's sense of efficacy after the interview: "I find accounting/finance even more interesting which is deeply reassuring since often I questioned whether I really wanted to go into this field. I found it surprising that the work can be so simple and that I don't need to be a genius to prosper in my field." The expectancy for success construct captures student's belief in their ability to succeed in the course or perform specific mathematical tasks.

In the category of utility, the use of basic mathematics (but not calculus) was mentioned in the majority of the written reports. The second most common response was that spreadsheets were useful. Some students were surprised to learn that business professionals used the same spreadsheet formulas that they were learning in class. For example, one student wrote "What did surprise me a lot, though, is how much he actually relies on Excel. I thought most people who work in real estate use it every now and then, but [interviewee] said he uses it in almost any project."

Finally, in the category of utility value, we did find some students who learned that school mathematics is not likely to be useful in their future career. For example, one student wrote, "I learned that even though I like math itself, like solving equations as we do in class, it won't be a part of the real world."

Table 2: Summary of Coded Interviews

Category & Theme	Example	Number of Reports
Expectancy		
Motivation / Self Esteem	Students identified that they could be successful and they "don't need to be a genius" to go into the field.	17
Networking / Mentoring	Interviewee identified the importance of networking and mentors for career success	14
Lack of Expectancy	<Did not appear in data set>	0
Utility		
Usefulness of Calculus	An options trader uses first and second derivatives to make trades	10
Usefulness of Excel/ Spreadsheets	Real estate professional uses Excel to do most calculations	33
Usefulness of Basic Mathematics (not calculus)	Small business owner uses math for budgeting and financial decision daily	76
Lack of Utility	Interviewee explicitly mentions calculus not used	11

Discussion and Conclusions

In the foregoing we have described student statements related to expectancy value on the basis of an interview assignment in an experimental Business Calculus class. We note that the primary source of data for this analysis is limited by the potential bias of students reporting what they thought we would like to hear. That is, the students may have written their responses to the interview assignment in a way that aligned with our hopes as course designers. Nonetheless, the ubiquity of responses that described the importance of spreadsheets and business mathematical calculations was encouraging. Also, many students explicitly said that they did not see the application of calculus in their interviews, which indicates that likely the students were honest in their responses.

The results of this work can inform future reforms to Business Calculus and the design of other introductory mathematics and statistics courses designed to serve client disciplines. In particular, aligning course content with the tools and practices of working professionals may be one way to increase students' expectancy and utility value. Our findings suggest that greater emphasis on spreadsheet-based modeling and authentic business applications may strengthen these connections. Additionally, this assignment—interviewing a professional—has significant potential for helping students (a) see the relevance of what they are learning and (b) develop networks with professionals in their intended career field. Future implementations could expand this effort through more career-relevance activities such as industry-based projects.

Acknowledgments

The pilot course development was supported by a grant from the California State University Chancellor's Office. All findings and conclusions of this work are the views of the authors.

IMPACT OF IMPLEMENTING THE BUILDING THINKING CLASSROOMS MODEL IN UNDERGRADUATE MATHEMATICS

Keywords: Undergraduate Mathematics Education, Teacher Education, Classroom Discourse, Active Learning

Purpose and Theoretical Framing

Building Thinking Classrooms (BTC) (Liljedahl, 2021) has been widely adopted in K–12 mathematics, where research documents increased student discourse, engagement, and problem solving through visibly random grouping, vertical non-permanent surfaces (VNPS), and rich tasks. In contrast, empirical work examining BTC in undergraduate mathematics remains limited. Emerging higher education studies report promising shifts in participation and collaboration (Reiser, 2023; Parrott, 2023; Douglas, 2024), yet systematic investigation of how BTC structures mediate discourse, knowledge mobility, and classroom community in tertiary mathematics contexts is still developing.

Related scholarship on collaborative problem-based learning and public workspace design in university mathematics similarly suggests that spatial and social structures shape mathematical interaction and visible idea refinement. Although Liljedahl's earlier work includes undergraduate participants, the full BTC model has not been extensively examined across diverse postsecondary mathematics settings. This gap is particularly notable given increasing calls for active learning and discourse-oriented instruction in undergraduate STEM education.

This study investigates how BTC structures function in several undergraduate mathematics courses—including 100-level general education courses, a 400-level geometry course for prospective teachers, and traditional calculus courses—at a regional comprehensive university. The guiding research questions are: (1) How does implementation of BTC structures influence student engagement and mathematical discourse? and (2) In what ways do students describe changes in their mathematical understanding and sense of classroom community? While the study has implications for teacher education, it is positioned primarily as a contribution to research on undergraduate mathematics learning in general.

Context and Method

BTC structures were implemented during the 25-26 school year. Core practices included daily visibly random grouping, problem solving at vertical whiteboard spaces, non-routine tasks (e.g., combinatorial generalizations; geometric investigations of Cevians and Menelaus), and structured teacher micro-moves such as rotating writers and group accountability for collective understanding.

Data sources include classroom observations, photographic documentation of vertical work, student written artifacts, end-of-course reflections, and instructor field notes. Analysis examines patterns of discourse, evidence of knowledge mobility, and student-reported perceptions of learning, engagement and community.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Preliminary Findings and Contribution

Preliminary analysis suggests increased student-to-student discourse, visible iteration of ideas, and greater willingness to publicly revise thinking compared to prior lecture-based iterations. Students describe a shift from individual performance toward collective problem solving and report deeper conceptual understanding and greater engagement.

By providing systematic documentation of BTC implementation across undergraduate mathematics contexts, this study extends emerging postsecondary BTC research and contributes to PME-NA conversations about instructional design, knowledge mobility, and active learning in tertiary mathematics classrooms.

TEACHING MATHEMATICS AS STORYTELLING: BRIDGING MICRO- AND MACRO-NARRATIVES IN ELEMENTARY CURRICULAR DECISION MAKING

We use storytelling to interpret mathematics teaching. Prior work treats stories literally, as word-problem contexts (Chapman, 2006; Depaepe et al., 2010), or metaphorically, as a property of curriculum (Dietiker, 2015; Dietiker et al., 2023). We instead adopt a narrative lens (Fisher, 1985): Teachers propose settings and events, and students co-narrate, reproducing and adapting narratives as they learn (Clark & Rossiter, 2008; Erickson, 2004; Ochs et al., 1992).

Micro-narratives are stories specific to a group's experience. Macro-narratives are broadly understood accounts of concepts (Devine et al., 2014), reproducible across settings and codified in standards. Teaching is then a loop rather than a transfer. Micro-to-macro bridging generalizes a classroom story into concepts students carry elsewhere; macro-to-micro bridging situates a concept within experiences that make sense to particular students. Closing the loop needs both rote reproductions, by which students internalize a story as taught and teachers assess what was learned, and creative reproduction, by which students apply a concept in a new setting.

We interviewed nine teachers at two elementary schools about their resources and coherence across lessons. To demonstrate the possibilities of a storytelling lens, we limit our findings to data from two teachers (Audrey and Sarah), both teaching second grade at the same midwestern school. These two teachers share curricular resources and institutional contexts and work toward the same macro-narrative. Yet they propose very different micro-narratives.

Audrey presented an Oreo taste test and built a whole-class line plot, holding that students must be "completely engaged before you can start teaching." Her whole-class lesson focused on generating one story, co-narrated by the group and reproduced as taught. Sarah's Survey Says had pairs poll classmates on questions they chose, allowing students to retell a known graphing story. This creative reproduction represents a micro-to-macro move. Sarah nonetheless feared hearing "you're not preparing them well enough for the test." implying a tension between standards-driven macro-narratives and locally meaningful micro-narratives.

A storytelling lens resists two binaries. Micro- and macro-narratives function as ends of a bridge rather than as a dichotomy: Audrey and Sarah work in both registers, differing in the direction and means of crossing. Attending to bridging surfaces the tension teachers manage between standards and particular students, and shows them meeting it through different strategies, advocating an empowered and diverse account of teachers. Seeing students as co-narrators credits what they contribute to the lesson and argues for enlarging that role. Rote and creative reproduction are similarly developmental rather than opposed: rote reproduction internalizes a story and lets teachers assess it, preparing the retelling in new settings that constitutes the macro-narrative.

PRESERVICE TEACHERS' FEEDBACK ON DIGITAL GAMES BASED TOOLS ON FRACTIONS AS FUTURE DESIGN IMPLICATION

Seyedehkhadijeh Azimi Asmaroud
Virginia State University
sazimi@vsu.edu

Boram Lee
Utah State University
boram.lee@usu.edu

Digital game-based learning has gained increasing attention in mathematics education and research shows positive effects of them for supporting fraction understanding; however, research highlights the need for further examination of effective design features and instructional integration. This study investigates two purposefully designed digital fraction tools, one game and an interactive app, and examines how Preservice Elementary Teachers' (PSTs) feedback offers insights for the future improvement of these tools. The study uses the ADDIE model (Hidayat et al., 2023) to guide the design of the tools and to analyze PSTs' feedback on the effectiveness of game elements and suggested modifications. The findings provide insights for educational game developers and educators on designing digital games that can be effective in supporting students' learning and knowledge of development of fractions.

Keywords: Digital Games, Preservice Teachers' Perspective, Fraction, Game Design Elements

Understanding fractions is a challenging concept for both students and preservice teachers (Gabriel et al., 2013; Satriyo et al., 2025). Digital game-based learning has gained increasing attention in mathematics education for its potential to foster engagement and support students' mathematical understanding (Beşaltı, & Kul, 2021; Fadda et al., 2021; Hussein et al., 2021). Research suggests that educational digital games can be particularly effective for teaching complex topics such as fractions (Beşaltı, & Kul, 2021; Hunt et al., 2025; Tangkui & Keong, 2021; Wardat et al., 2022; Zhang et al., 2020). While many studies have explored the effectiveness of educational digital games, further research is needed to examine the design features and key elements that make learning games effective for mathematics instruction (Gui et al., 2023; Pan et al., 2022), specifically in fraction learning (Thoma et al., 2023).

Research indicates that mathematics teachers perceive digital games as valuable instructional tools (Da Cruz et al., 2025; Mazuru & Popa, 2025); however, limited knowledge about how to effectively integrate digital games into instruction can discourage their use as a primary teaching approach (Matic et al., 2023).

This study explores the use of two purposefully designed digital tools for fraction instruction, a mobile video game and an interactive app. In this study, we integrated these digital tools into a mathematics education program for elementary preservice teachers and examined their feedback regarding the challenges they encountered, areas for improvement, and recommendations for redesigning the tools. Thus, the research question is:

How do preservice elementary teachers evaluate the effectiveness of digital game-based tools on fractions, and what implications does their feedback offer for the future design of the tools?

Literature Review and Theoretical Framework

There is substantial empirical evidence indicating that students' understanding of fractions predicts later achievement in advanced mathematics (e.g. Bailey et al. (2012), Hansen et al., (2017), and Siegler et al. (2012)). However, many students still experience difficulties with fraction concepts (Di Lonardo Burr et al., 2022; Hariyani et al., 2023). Research also shows that fraction as measurement (Wilkins & Norton, 2018), fraction as part–whole (Gabriel et al., 2013:

Pramudiani et al., 2022; Rosli et al. (2020), and fraction equivalence (Deringöl, 2019; Girgin & Altay, 2023; Hariyani et al., 2023) are challenging topics for both PSTs and elementary students. Furthermore, a review of 70 research studies by Perry (2023) showed that using measurement and number lines helps PSTs improve their general fraction knowledge.

This study draws on the ADDIE model by Hidayat et al. (2023) which has been developed based on constructivism learning theory (Zhang et al., 2023) and supports the alignment of instructional materials with learners' needs and educational objectives. This model has widely been used to develop digital teaching materials and educational games (Nuntawisuttiwong & Dejdumrong, 2024; Widyastuti, 2019; Zhang et al., 2023) and suggests five steps in game development: Analysis, Design, Development, Implementation, and Evaluation (See Figure 1).

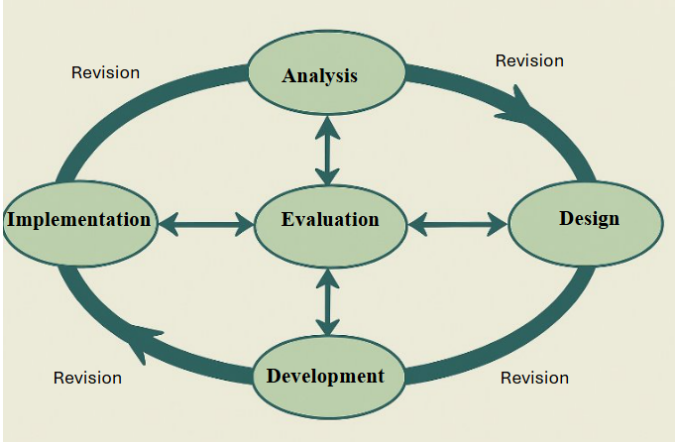

Figure 1: ADDIE Model by Hidayat et al. (2023)

In this section, we elaborate on the stages of this model based on the descriptions provided in Zhang et al. (2023). The *analysis* stage phase includes problem identification, needs analysis, and identifying the target audience. The *design* stage includes creating a learning environment outline, mapping evaluation methods, developing a communication strategy, aligning learning objectives with specific game elements, and creating concept art. The development stage is the production of game products: creating game strategies, designing media and instructional methods, and developing and evaluating assessment tools. The *implementation* stage involved launching the game, training participants, and carrying out the game's use in the study. The *evaluation* stage involved assessing the game overall, examining its effectiveness, evaluating participants' interactions with the game, and reviewing each stage of the design and implementation process. Specifically, in this study, we zoomed in on the *evaluation* stage with preservice teachers on two different digital tools developed around fractions. More details about the two digital tools and the context of the data are described in the Methods section. The following result section addresses preservice teachers' feedback on the two tools drawn on the lens of the evaluations stage of the ADDIE model.

Methods

The study was implemented in two mathematics education content courses for elementary preservice teachers in Spring 2025, with the goal of exploring their perspectives on using a mobile game and a game-based app, both of which were developed by the second author, for teaching fraction concepts. Data were collected at the end of the semester, after students had

learned the mathematics concept of fractions. These courses are designed to deepen preservice teachers' conceptual understanding of elementary mathematics topics, including fractions. During class time, students engaged individually with the mobile game and the digital app, followed by survey questions prompting reflection on their experiences. Participants included 66 volunteer PSTs who registered for the courses and agreed to complete the study.

Designing and Developing the Game and the Interactive App

In the game-based app, players need to figure out the length of a green stick based on the blue stick length being 1. Players can change the number in the blue box by manipulating the two arrows. Based on the selected blue number, blue divider sticks are created on the number line (Figure 2-left). If the selected blue number is a proper value as a denominator, the green box gets filled with a corresponding value. The design intends for players to coordinate the green number and the blue numbers to construct the meaning of numerator and denominator in a number line context. The digital game incorporates more graphics and interactive elements. Players are required to create a cloud by manipulating blue and green numbers in the boxes to block a stone falling from the sky (Figure 2-right). To create a cloud at a position players want, they need to manipulate the blue and green numbers, where blue numbers represent denominator and green numbers represent numerator. If players block at least one stone in each stage, they can move to the next stage (check the link for the app and the game for more details). The app was designed more as an interactive tool to be used by the teacher during instruction, so the teacher was expected to monitor students' gameplay as they engaged with the app. In contrast, the game was designed more as a structured fraction-learning game which players can figure out how to play the game (e.g., the tutorial stage) without supports from others. Within the game, even though the teacher could provide students with instruction, it was designed more as a structured fraction-learning game which players can figure out how to play the game (e.g., the tutorial stage) without supports from others; the design intends to support players to develop the understanding on fractions while proceeding the game stages.

Game

Figure 2: Developed App and Game in Development Stage

Data Collection

Participants engaged with both the game and the app for approximately 20 minutes for each tool at the end of two class sections, after having learned about the fraction concept during the semester. Each participant worked individually, allowing them to explore the app and game at their own pace. During this time, the teacher observed and provided minimal guidance, ensuring

that participants could navigate the tools independently while applying their understanding of fractions. From the students enrolled in both classes, 36 responded to the app survey question, and 30 completed the Digital Game survey. Both surveys included three scaled questions, effectiveness, clarity, engagement and two open-ended questions around improvement and challenges in common. We report on the participants' responses to the 5 questions in this paper. In the scaled questions, PSTs rated their perspectives on the effectiveness, clarity and the engagement of game and app on a scale of 1 to 10. Open-ended questions were "What challenges did you face?" and "What improvements would you suggest?" In the scaled questions, PSTs rated their perspectives on the effectiveness and the engagement of game and app on a scale of 1 to 10. Open-ended questions were "What challenges did you face?" and "What improvements would you suggest?" Qualitative responses to the open-ended questions were analyzed using open coding (Williams & Moser, 2019); responses were initially coded by two authors independently and then reviewed collaboratively to identify emerging themes.

Results

In this section, we describe the results based on the *Evaluation* stage of the ADDIE Model. PSTs' responses to the question "How effective did you find the app/game in enhancing understanding of fractions?" indicated that overall, both the app and the game received positive user feedback. The game's ratings are slightly more concentrated in the higher range (7–10), while the app's ratings are more spread out across the mid-level range (3–6) (see Figure 3).

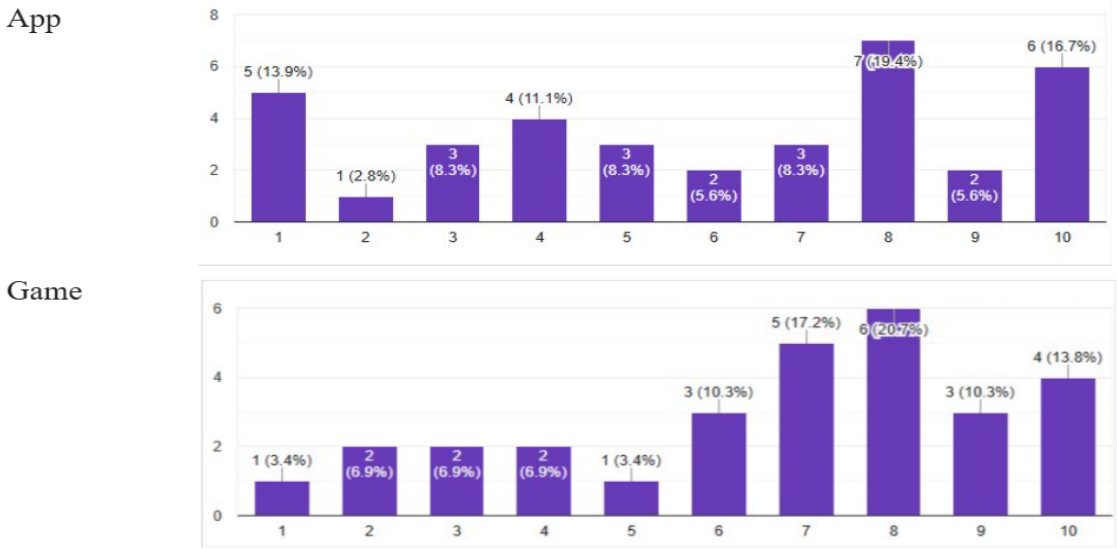

Figure 3: PSTs Responses to the Effectiveness of the App and Game in Understanding Fractions Concepts

Similarly, in PSTs' response to the question "Were the objectives and instructions clear and easy to follow?," the app rating shows a more evenly distributed pattern, whereas the game is more heavily concentrated in the higher range (7–10) (Figure 4). The game's strong peak at 8 suggests higher overall satisfaction compared to the app. This implies that PSTs perceived that the game has clearer instruction than the app does.

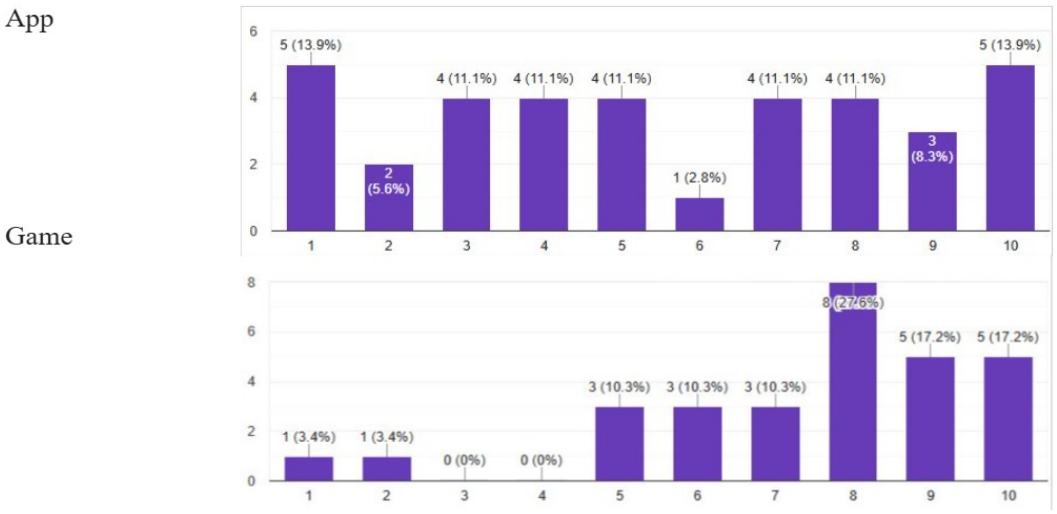

Figure 4: PSTs Responses to the Clarity of the Instructions

In response to the question "How engaging did you find the App/game for teaching the fraction concept?," PSTs' responses revealed that the app received a mix of ratings centered around five and seven, while the game showed a much stronger skew toward high engagement and satisfaction.

Figure 5: PSTs Responses to the Engagement of the App and Game

In analyzing PSTs' responses to two open-ended questions about the challenges they faced and their suggestions for improvement, several themes emerged, including instruction, immediate feedback, game loading time, time limits, repetitiveness, and math concepts (see Figure 6).

Note. For the Digital App, the number of responses was 36 and for the Digital Game, it was 30.

Figure 6: Challenges PSTs Faced and Their Suggestions for Improvement

Out of the responses collected about the game, 15 participants (50%) stated that they did not encounter any challenges, suggesting that the game was generally easy to use and accessible for PSTs. For the app, nine participants (25%) reported no challenges. From the participants that reported challenges, unclear instruction on how to play either the game or app (coded as Instruction) was the most frequently mentioned challenge for both the app and the game (50% of the responses for the app and 20% for the game). Consistent with this challenge, 56% of PSTs recommended adding clearer instructions, a tutorial, or a trial feature to the app as a possible improvement. For the game, this percentage was 17%. Although the game already included a tutorial, some participants still commented on the need for clearer instructions on how to play. This suggests that clarity of instructions played an important role in PSTs' experiences.

Lack of immediate feedback was mentioned by three PSTs as a challenge for the app (coded as Immediate feedback), while no comments about feedback were identified as a challenge for the game. However, in their improvement suggestions for both tools, PSTs highlighted that providing immediate feedback for correct or incorrect solutions is an important factor for enhancing learning and engagement in digital tools.

Four PSTs mentioned challenges with the *math content* covered in the game, while only one PST referred to this issue in the app. In their suggestions for improvement, participants recommended adding a tutorial to review the concepts, explaining the concepts within the questions, or including a video or voice guidance to provide clearer instruction on the math content.

Discussion and Implications

In this study, we explored PSTs' perspectives on an app and a game designed for fraction concepts. Specifically, we examined their feedback to see how their feedback can be used as implications for further design refinement. As the cyclic features of the ADDIE model suggest, the results from the survey questions will lead us to redesign the app and the game, making them more effective tools for instructional use.

From these findings that showed the current design of instruction was the most frequently mentioned challenge for both tools, and that over half of the PSTs recommended adding or improving instructional support for the app, we conclude that clear and accessible instructions for digital tools are what PSTs perceive as an important factor when considering using the tools for math learning. This will guide us in the next phase of redesigning the app to add more clear instructional support. The redesign will include (a) Task-specific micro-instructions: place a 1–2 line explanation about "What to do" panel at the top of each activity, (b) Try/Practice mode: A friction-free "trial round" with no scoring, just exploration to be used before the main activity page shows up.

Lack of immediate feedback was mentioned by some PSTs as a challenge. In their improvement suggestions, PSTs highlighted that providing immediate feedback is an important factor for enhancing learning and engagement in digital tools. This finding is supported by previous research. For example, a meta-analysis by Van der Kleij et al. (2013) showed that elaborated feedback produced larger effect than feedback that only indicated the correctness of an answer or provided the correct answer. Also, it showed that the effects of the feedback were affected by delayed feedback timing. Furthermore, Barana et al., (2021) defines interactive feedback as "a step-by-step interactive solving process that guides learners in completing a task after one or more independent attempts" (p. 6) in technology environments, based on theories of automatic and formative assessment. They found that interactive feedback, not correct or incorrect or rewards, is effective at helping learners improve their performance. In the redesign of the app and the game, we plan to incorporate both interactive feedback for content-related feedback (e.g., guidance on math concepts and problem-solving strategies) and technology-based feedback (e.g., rewards, stars, and scores) to further motivate and engage learners.

Furthermore, based on the finding that we received more comments about the math content in the game compared to the app, a plan for the next step for redesigning the game is as follows: the game requires additional scaffolding for math content to maximize both its effectiveness and student engagement. Because the design intention of the interactive app and game is to be used as instructional tools to be integrated into learning, rather than being used as a review tool only after students have learned the concept, we plan to include a brief conceptual review within the tool following completion of the game and app. This addition is intended to support students who may not fully grasp the concept after interacting with either tool alone. Also, even though we received only one comment noting that the game and app were repetitive, this prompted us to add more variety to the questions in both tools.

This study primarily focused on collecting feedback and perspectives of PSTs, rather than measuring actual learning gains or changes in teaching practice. In our larger study, we administered a pre-test and post-test knowledge check, which we plan to report in future work. Additionally, given the tools were designed specifically for teaching fractions and were limited to the particular app and game used in this study, the findings may not generalize directly to other math topics or digital tools. Nevertheless, the study provided valuable insights into the design and instructional use of educational technology from the PST's perspective; the results provide insights for educational game developers and educators on how to design digital games that are both engaging and effective in supporting teachers and students in teaching and learning fractions.

Mathematics learning is cumulative, yet many representations of development remain descriptive rather than operational. Persistent difficulty in geometry and data analysis is often attributed to topic-level complexity but may reflect unresolved gaps in earlier knowledge. This conceptual paper examines the gap between descriptive progressions and models capable of inferential personalization. Drawing on Mastery Learning, the Zone of Proximal Development, and Knowledge Space Theory, we articulate three requirements: sufficient granularity, explicit precursor–successor encoding, and inferentially coherent knowledge states. We bring two forms of evidence to bear: error patterns in generative AI systems lacking structured knowledge models, and the architecture and pilot results of a system that satisfies them. Formalizing these dependencies is necessary for diagnosing cumulative difficulty.

Keywords: Learning Theory, Learning Trajectories and Progressions, Assessment, Technology

Introduction

Large-scale assessment data continue to reveal persistent and troubling patterns in middle and secondary mathematics performance. National and international assessments indicate that students struggle with domains such as geometry, data analysis, statistics, and probability (National Center for Education Statistics [NCES], 2022; Organisation for Economic Co-operation and Development [OECD], 2023). These findings are often interpreted as evidence that particular mathematical domains are inherently difficult. However, growing evidence suggests that many of these difficulties reflect unresolved gaps in earlier foundational knowledge rather than domain-specific complexity (Burleigh & Durkin, 2026).

Mathematics is structurally cumulative. Later competencies depend on earlier conceptual structures, including whole number understanding, multiplicative reasoning, spatial structuring, and relational thinking (Clements & Sarama, 2020; Siegler et al., 2012). When this foundational understanding is incomplete, students may develop what is sometimes described as "Swiss cheese" foundations: knowledge that appears intact on the surface but obscures hidden structural gaps. These gaps may remain undetected for years before emerging as difficulty in algebra, geometry, or data analysis. In such cases, the visible struggle is not located in the advanced topic itself, but in earlier, underdeveloped precursor understandings.

Research on early number development illustrates this cumulative structure. As an example, Baroody and colleagues (2009) argue that fluency with basic number combinations does not arise from rote memorization alone, but from the gradual construction of interconnected numerical relations and reasoning strategies. When these relational structures are insecure or incomplete, later learning becomes difficult and unstable. In some cases, incomplete foundational development may be misinterpreted as mathematics disability rather than as a constellation of unresolved precursor gaps that could be identified and addressed (Baroody et al., 2009).

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Foundational learning theories rest on similar structural assumptions. Bloom's Mastery Learning presumes that prerequisite understandings can be identified and secured before advancing (Bloom, 1968). Vygotsky's (ZPD) of Proximal Development presumes that for each learner, adjacent and reachable knowledge can be determined within a structured space of understanding (Vygotsky, 1978). Likewise, research on mathematics learning trajectories articulates increasingly sophisticated forms of reasoning and developmental ordering (Clements & Sarama, 2020; Fonger et al., 2018). Across these perspectives, learning is treated as structured and cumulative. Yet there remains a representational gap: while these frameworks describe how understanding develops, they do not always specify how prerequisite relations should be formally encoded so that learner readiness can be systematically inferred and automated, such as in adaptive learning systems.

This paper argues that if AI-driven personalization is to address cumulative mathematical difficulty rather than merely respond to surface performance, it must be grounded in formally structured knowledge models that decompose mathematical knowledge into sufficiently granular components with explicitly represented dependency relations. This is a conceptual paper, and its argument proceeds analytically rather than through the test of a hypothesis. The sections that follow articulate why descriptive progressions are insufficient for this purpose and specify three representational conditions that content-structural personalization requires. We then bring two forms of evidence to bear on those conditions: a documented set of recurring failures in generative AI systems that lack structured knowledge models, which shows what their absence produces, and the architecture and pilot results of an adaptive system built to satisfy them, which shows that they can be implemented. We close with implications for how the field interprets and addresses mathematical difficulty.

Progressions Are Not Enough for AI-Driven Personalization

The mathematics education community has invested substantial effort in articulating learning trajectories and progressions that describe how students' mathematical understanding develops over time (Clements & Sarama, 2020; Confrey et al., 2014). These frameworks have advanced the field by identifying typical developmental pathways, highlighting common misconceptions, and emphasizing the cumulative nature of mathematical knowledge.

However, learning progressions are primarily descriptive. They specify common sequences of development but do not always formalize the structural dependencies required for systematic inference about individual learners. A progression may indicate that Concept B tends to follow Concept A but does not necessarily specify whether mastery of A is logically required for B, whether partial mastery suffices, or whether certain knowledge states are structurally impossible. Developmental order is not the same as structural constraint.

This distinction becomes especially consequential in early childhood mathematics. Foundational domains such as whole number understanding are often described at a relatively broad level, for example, through constructs such as counting, cardinality, or part–whole reasoning. Yet each of these contains multiple interdependent components. Stable count sequence, one-to-one correspondence, cardinality, relational comparison, additive composition, and unitizing are distinct but structurally related forms of understanding. Treating these as a single construct obscures the internal dependency relations that determine whether later learning is accessible.

When knowledge is represented at a coarse grain size, important precursor relations remain implicit. A learner may demonstrate correct performance on a task associated with "cardinality" while still lacking flexible part–whole reasoning. The absence of specific precursors constrains

what successor understandings are reachable, but without sufficient granularity, such constraints remain invisible. Adaptive systems may interpret surface accuracy as evidence of readiness for advancement without distinguishing which successor states are accessible and which remain out of reach. In such cases, personalization may recommend tasks that appear aligned with recent performance but reinforce fragmented foundations rather than strengthening them.

Structural Requirements for Content-Structural Personalization

If mathematical knowledge is cumulative and structurally organized, then personalization requires representational commitments that make prerequisite relations explicit and inferentially usable. Adaptive systems must reason about structure, not merely about performance. This imposes three representational conditions on any knowledge model intended to support automated and principled personalization: sufficient granularity, explicit encoding of precursor–successor relations, and inferential coherence of knowledge states.

(1) Granularity as a Representational Threshold

Personalization presupposes that knowledge can be represented at a level of resolution fine enough to identify missing components without collapsing distinct forms of understanding into broad constructs. Macro-level categories such as "number sense," "place value," or "fractions" conceal the internal structures that determine whether later learning is accessible.

As noted above, whole number competence comprises many interdependent components (Clements & Sarama, 2020; Siegler et al., 2012). Baroody and colleagues' (2009) work further emphasizes that fact fluency emerges from structured numerical relations rather than isolated memorization. Each of these components supports distinct successor structures. When knowledge is represented too broadly, diagnostic precision suffers. It becomes impossible to determine which specific precursors are missing. Faithful modeling of early mathematics may therefore require representing hundreds of distinct but interconnected knowledge units (KUs) even within a limited developmental span. Such a level of resolution better reflects the genuine complexity of foundational learning rather than the convenience of assessment design.

(2) Explicit Precursor–Successor Encoding

Granularity alone is insufficient. Representing discrete KUs does not guarantee that their relations are formally specified. Operationalizing personalization requires explicit encoding of which relations are logically or developmentally constraining.

Learning progressions describe typical developmental orderings. However, operational knowledge models must go further by specifying which successor understandings depend on which precursors (often representing multiple such relationships). Knowledge Space Theory provides one formal articulation of this requirement by representing knowledge as a set of states governed by prerequisite relations (Doignon & Falmagne, 1985; 1999). Within such a framework, mastery of specific concepts constrains which successor states are reachable. If a learner lacks a particular precursor, certain successor understandings remain inaccessible regardless of exposure or practice.

This formalization clarifies the cumulative nature of mathematical difficulty. Consider multiplicative reasoning, which underlies fraction equivalence, proportional reasoning, and aspects of algebraic thinking (Siegler et al., 2012). When multiplicative structures are incomplete, later struggles may appear in domains that are distal from early number development. Spatial structuring in early geometry likewise predicts later facility with area, volume, and formal proof (Clements & Sarama, 2020). Difficulties observed in middle school domains such as geometry or data analysis may therefore originate in earlier, unresolved structural gaps. Without explicit encoding of precursor–successor relations, an adaptive system

can only respond to the present visible performance; it cannot recognize that advancement is constrained by an absence it has no means of representing or locating within the adaptive system. Accurate diagnosis requires a model of dependency, not merely a record of outcomes.

(3) Inferential Coherence and Knowledge State Closure

A third requirement concerns inferential coherence. Personalization requires reasoning not about isolated skills, but about structured knowledge states. If adaptive systems are to approximate principles such as mastery learning or leverage an individual learner's ZPD, they must identify what forms of understanding are adjacent, reachable, and possible given a learner's current knowledge state (Betts et al., 2024).

Within formal knowledge space frameworks, a learner's knowledge state is defined as a set of mastered KUs that satisfies closure under prerequisite relations (Doignon & Falmagne, 1999). States that violate dependency constraints are excluded as impossible. This constraint-based representation allows systematic reasoning about a learner's space of possible next steps and makes visible which understandings remain out of reach.

Without this third condition, personalization is driven by patterns in performance rather than by the architecture of knowledge itself. A learner who answers several items correctly may be advanced to new content with no representation of what that advancement presupposes. This is distinct from advancing a learner past content that has not been directly observed. Closure under prerequisite relations makes that inference possible: when a learner demonstrates a successor understanding, the precursors it depends on may be inferred as mastered rather than treated as skipped, which is what allows structured systems to assess efficiently and to probe the upper reaches of a learner's ZPD. The difference is diagnostic. In a structured model, a failed probe localizes the dependency on which the inference rested; in a performance-driven system, the same failure is only an incorrect answer. Undiagnosed gaps tend to re-emerge as the demands of later content increase, and a system without dependency structure cannot distinguish a genuine gap from an unobserved mastery.

These three conditions, (1) granularity, (2) explicit dependency encoding, and (3) inferential coherence, form a mutually reinforcing representational threshold: granularity without dependency encoding produces isolated fragments; dependency encoding without coherent state reasoning cannot determine which next steps are reachable; state reasoning without sufficient granularity operates on constructs too coarse to support diagnosis. Any system that omits one condition undermines the others.

The Representational Gap in Practice: AI Errors in the Absence of Structural Models

Systems that attempt to support early mathematics learning without the representational requirements specified in the previous section fail in observable and predictable ways. To examine those failures, we prompted several largen language models (LLMs), including ChatGPT, Claude, Perplexity, and Gemini, to generate early mathematics activities targeting specific KUs drawn from a granular developmental progression spanning numeracy, geometry, and measurement (Betts, 2025). In each case the model was supplied with the full KU learning progression as text, including the position of the target KU within the sequence. The patterns reported in this section are those that recurred reliably across prompts, models, and content domains.

LLMs are increasingly used by parents and educators to generate early mathematics activities, often by those with the least domain-specific training and therefore the greatest need for reliable guidance (Betts, 2025). Yet across platforms, these systems exhibit persistent patterns of developmental misalignment, concept conflation, and boundary violation when

generating content for early mathematics. These errors are the structurally predictable consequences of operating without the representational infrastructure that content-structural personalization requires.

Let us consider a concrete case. When prompted to generate activities for the foundational measurement KU "*Shows awareness of size, and uses appropriate language to describe such as big, small, giant, tiny*," one LLM immediately proposed a sorting activity requiring children to classify objects into size categories (Betts, 2025). Sorting presupposes comparison and classification, which are developmentally subsequent to recognition and labeling. The system had itself articulated where this KU fell within the sequence. Yet it continued to consistently generate activities targeting skills several steps ahead of the intended level. When corrected, it acknowledged the error accurately, and then produced another activity requiring children to order objects from big to small, targeting a later KU in the same progression.

This pattern (i.e., surface-level acknowledgment followed by repeated structural violation) is diagnostic. The progression was available as descriptive text, but the precursor–successor relations were not encoded in a form that could govern the AI's inference. Without explicit structural constraints, the system treated the progression as a list of related topics rather than a set of ordered dependencies. It could recognize a mismatch when told about one, but could not prevent the next occurrence, because it had no mechanism for reasoning about which knowledge states were reachable from a given developmental position.

A second class of error illustrates the consequences of missing granularity. The system conflated size vocabulary (big, small) with length vocabulary (tall, short), describing a flower as "short and small" within a single activity (Betts, 2025). In early mathematics, size and length refer to distinct measurable attributes that require different mental models, tools, and units. This distinction underlies later differentiation of area from perimeter, volume from surface area, and one-dimensional from multi-dimensional measurement. When a system collapses these attributes into interchangeable descriptors, it models a conceptual conflation that, if implemented by a non-expert adult, may become embedded in the child's developing understanding as a misconception.

These failures were not isolated. Across numeracy, geometry, and measurement, generative AI systems routinely confused verbal count sequence with one-to-one correspondence, proposed backward counting when forward skip counting was specified, conflated part–whole reasoning with conservation of number, and generated contextually implausible activities disconnected from children's lived experiences (Betts, 2025). Each category of error maps onto the absence of a specific representational condition: boundary violations reflect missing dependency encoding, attribute conflation reflects insufficient granularity, and contextual implausibility reflects the absence of inferentially coherent knowledge states.

Most AI-embedded educational products for early mathematics are, in practice, general-purpose language models with an educational interface (Betts, 2025). Very few have been trained on rigorously vetted, research-based knowledge models, largely because such models barely exist at the level of granularity and formal structure required for truly adaptive AI-driven "smart" learning systems. This reflects a broader "triple expertise gap:" (1) practitioners lack deep domain-specific knowledge of early mathematics, (2) society perceives early math as simple, and (3) the field has too few specialists to build the knowledge infrastructure that both educators and AI systems require (Betts, 2025; Ban et al., 2024). AI systems trained on this fragmented knowledge base do not invent new misconceptions; they reflect and amplify existing ones with a confidence that makes detection by non-experts unlikely.

Content-Structural Personalization in Practice

If the preceding section illustrates what happens when the representational conditions for content-structural personalization are absent, PAL (Personal Assistant for Learning), an adaptive learning system for early mathematics, stands as evidence that those conditions can be operationalized within an adaptive system, producing measurably different design decisions and outcomes (Betts et al., 2026).

PAL is an adaptive learning system grounded in sociocultural theory, Knowledge Space Theory, and learning sciences principles that supports early mathematics learning by guiding parents and teachers to facilitate hands-on, socially mediated interactions aligned with each child's ZPD (Betts et al., 2026). Its architecture instantiates each of the three representational conditions identified in this paper. Firstly, sufficient granularity is realized through hundreds of developmentally sequenced Knowledge Units (KUs), each representing a discrete concept or skill at a resolution fine enough to distinguish between components routinely collapsed in curricular standards (e.g., between labeling objects using size vocabulary and sorting objects by size, etc.). Secondly, explicit precursor–successor encoding is realized through a directed conceptual graph in which prerequisite relations among KUs are formally specified, capturing the branching, converging nature of early mathematical development and preventing the system from recommending activities that target unreachable knowledge states (Figure 1). And lastly, inferential coherence is realized through an explore–exploit adaptive engine that probes emerging readiness on adjacent KUs while consolidating understanding in areas of strength, informed by lightweight adult feedback (e.g., "did independently," "needed help," "struggled") and brief KU-aligned digital assessments.

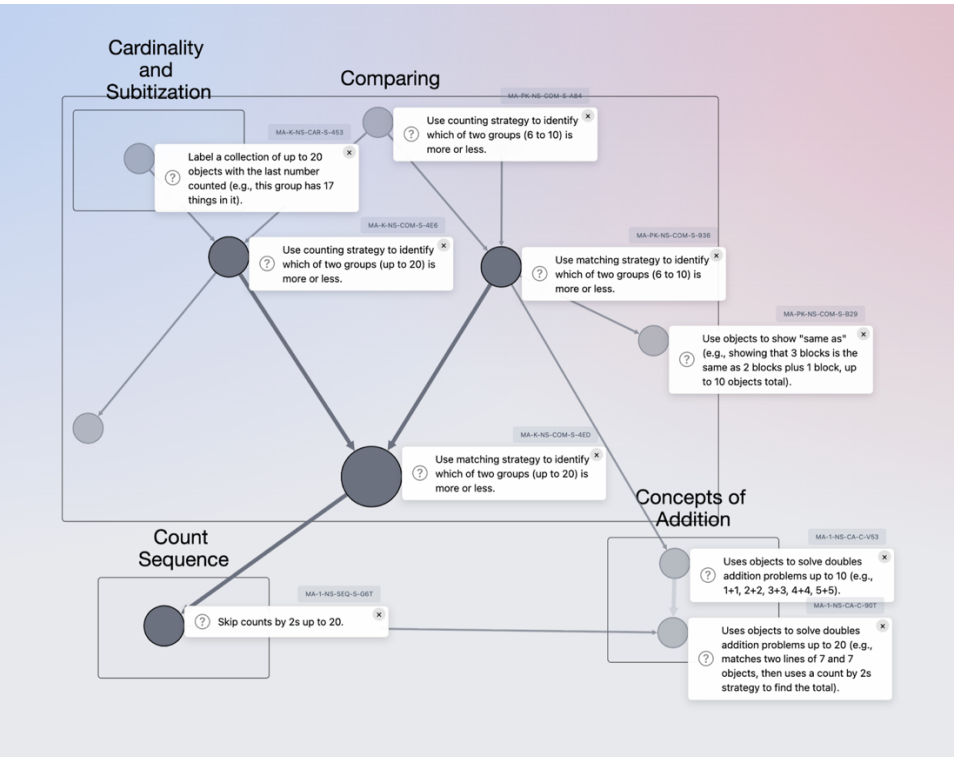

Figure 1: Model of Precursor–Successor Relations Among Knowledge Units in Early Number Sense, Comparisons Topic

A notable feature of PAL is that it does not require children to interact directly with a digital device. PAL's personalization operates on structural knowledge states inferred from adult-reported evidence and periodic assessments rather than on real-time screen-based performance, and learning takes place through hands-on, adult-mediated activities embedded in everyday routines, making them more developmentally appropriate for young learners. While PAL does feature periodic digital assessments, these are not required and can also be done in an offline manner. This approach follows from the representational architecture itself. If the knowledge model is granular enough, the dependencies explicit enough, and the state inference coherent enough, then the system can guide learning through any interaction modality that produces evidence at the appropriate grain size. The adult becomes both the mediator of learning and a source of structured evidence, operationalizing sociocultural theory's concept of the "more knowledgeable other" (Vygotsky, 1978) within a computationally grounded adaptive framework.

Early evidence from two exploratory implementations is consistent with these predictions. In a randomized pilot with prekindergarten families from under-resourced communities ($n = 18$), children whose parents received PAL showed greater growth on the TEMA-3 than a business-as-usual comparison group ($p < .01$; Cohen's $d = 1.71$), and parent engagement was positively associated with gains (Spearman $r = .62$, $p = .003$; Betts et al., 2026a). A second study varying nudge frequency over seven months ($n = 39$) found that the number of nudges a family received predicted children's growth ($r = .51$, $p < .001$), a relationship that held after adjusting for baseline achievement (partial $r = .54$, $p < .001$; Betts et al., 2026b). Both samples are small and neither was designed to isolate the knowledge model's contribution from that of adult mediation; we report them as directional. What they establish here is that these representational commitments are implementable at the granularity this paper argues for, and a system so structured can generate next steps that children are ready to take.

Implications for Mathematics Education Research

The analysis presented here carries several implications for how the field interprets mathematical difficulty, designs adaptive systems, and directs research effort.

First, content-structural personalization reframes the interpretation of difficulty itself. When dependency relations are not explicitly modeled, observed performance deficits tend to be attributed to domain difficulty, insufficient effort, or learner disposition. If knowledge is structurally cumulative, however, many instances of apparent difficulty may instead reflect unresolved precursor gaps. The cascading patterns observed in large-scale assessment data (e.g., student struggle with geometry, data analysis, algebra, etc.), are consistent with this structural interpretation. A student struggling with proportional reasoning may receive remediation in algebraic procedures without identification of incomplete multiplicative foundations. Similarly, a student labeled as having a mathematics disability may exhibit a constellation of missing precursors that were never systematically diagnosed. A structurally explicit knowledge model does not eliminate the possibility of genuine learning disabilities; it reduces the risk of conflating missing learning opportunities with inherent incapacity, shifting the focus from labeling to structural diagnosis.

Second, this perspective clarifies what constitutes theoretically grounded personalization in the context of adaptive technologies. Without explicit structural modeling, adaptive systems reproduce the same descriptive limitations found in traditional progressions, in other words, responding to visible performance rather than diagnosing the structural conditions that produce

it. The evidence from generative AI systems confirms that access to descriptive progressions alone is insufficient; the errors these systems produce are precisely those predicted by the absence of formal dependency encoding. Content-structural personalization requires that knowledge models make cumulative structure visible and diagnostically actionable.

Third, the challenge for mathematics education research is not merely to describe how understanding develops, but to formalize the structural relations that make development inferentially tractable. This is a different kind of research enterprise than articulating learning trajectories; it requires specifying which relations are constraining, validating prerequisite structures empirically, and building the knowledge infrastructure that both human educators and AI systems need. If mathematical learning is cumulative, then its representation must be structurally cumulative as well.

Conclusion

This paper has argued that AI-driven personalization in mathematics education requires explicit representational commitments that most current systems do not make: sufficient granularity to differentiate component knowledge structures, explicit encoding of precursor–successor relations, and inferentially coherent knowledge states. These conditions are not optional enhancements to existing adaptive approaches. They constitute the minimal infrastructure for personalization that can diagnose structural gaps rather than merely react to surface performance. The observable failures of generative AI systems in early mathematics confirm what the theoretical argument predicts, and the design of systems like PAL demonstrates that these conditions are achievable. What remains is the harder work: building, validating, and sharing the structured knowledge models that this form of personalization demands—and reckoning with the cost, to children and to the field, of continuing without them.

GENERATIVE AI AS A MATHEMATICAL LEARNING TOOL: AN ANALYTICAL FRAMEWORK PROPOSAL

Jon D. Davis
Western Michigan University
jon.davis@wmich.edu

Generative artificial intelligence (GenAI) gained unprecedented public support upon its launch in November 2022. Initially dismissed by many educational stakeholders, the educational establishment is gradually welcoming it. GenAI resembles earlier mathematical action and communication technologies but also has unique capabilities, such as conversing with a student primarily in writing. Consequently, this theoretical research report reviews frameworks for examining students' use of technology to do and learn mathematics, which I describe as a mathematical learning tool. This report proposes an analytical framework comprising nine dimensions that builds on prior frameworks, addresses their gaps, and accounts for the unique capabilities of GenAI. Some of these dimensions include equity and access, GenAI function and instrumentalization, epistemic control, discourse, and technology mediation.

Keywords: Technology, Artificial Intelligence, Analytical Framework

Introduction

ChatGPT, the first large language model (LLM) and generative AI system (hereafter referred to as GenAI), became publicly available in November 2022 and reached 100 million users within two months, making it the fastest-downloaded application in history (Hu, 2023). While GenAI initially struggled with mathematical tasks (e.g., Davis, 2025b), it has since become highly effective across a range of mathematical tasks (Metz, 2024). Consequently, they join a long list of mathematical technological tools that were developed for other purposes but found a home in schools (e.g., spreadsheets), as well as tools specifically designed for mathematics education, such as virtual manipulatives. They certainly share features with prior mathematical tools, such as calculators, but they are also used in different ways (e.g., via natural language) and have different capabilities (e.g., in developing mathematical arguments). Moreover, although research on GenAI has used previously developed frameworks (e.g., Davis, 2025a), these frameworks do not capture the unique capabilities of GenAI or the primarily text-based ways users interact with the technology. This paper argues that, given GenAI's unique capabilities, a new analytical framework is required to investigate its role as a *mathematical learning tool* for students. While frameworks unique to GenAI are needed, it is important to note that such a framework may need to be in a constant state of flux as the capabilities of these systems change rapidly.

Background

Categorizing Educational Technologies

Dick and Hollebrands (2011) used the terms "conveyance technology" and "mathematical action technology" to distinguish two types of technologies that can be leveraged for educational purposes. The first refers to technologies that convey information in an educational setting, such as a document camera. Mathematical action technologies operate on different representations of mathematical objects, such as performing calculations, plotting graphs, constructing geometric objects (e.g., a line perpendicular to another), and manipulating algebraic symbols, as in a computer algebra system (CAS). A common example of a mathematical action technology that incorporates all these functions is a TI-Nspire CX CAS handheld calculator.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Drijvers, Stacey, and Trouche (2024) used the terms *communication infrastructure* and *computational infrastructure* to denote distinct types of technology. The former aligns with Dick and Hollebrand's (2011) conception of conveyance technology, but the latter is somewhat broader. It includes technologies that operate on or produce mathematical representations, as well as technologies that execute computer code and employ earlier forms of AI, such as those used in facial recognition. Recently, GenAI has demonstrated the ability to construct mathematical arguments (Liu et al., 2025). Thus, the term computational infrastructure should be further broadened to encompass these new mathematical capabilities. Furthermore, GenAI more closely integrates communication and computational infrastructure within a response, suggesting that these components should be more closely connected.

Not only does GenAI expand the capabilities of computational infrastructure and suggest a more closely intertwined computational and communicational infrastructure, but it also enables interactive instruction for students through tutoring. Indeed, the U.S. Department of Education (2023) has argued that one of the educational strengths of GenAI is its ability to provide personalized feedback to students as they learn a mathematical idea. While students can interact with prior mathematical technologies to deepen their understanding, GenAI enables them to pose their own questions to further their understanding.

Students' Use of Technology to Offload or Learn Mathematics

When students use mathematical action technologies or computational infrastructure to perform a task, they can do so in two ways. First, it can be used to perform, execute, or offload mathematical work, which Drijvers (2012) refers to as *doing mathematics*. Second, it can be used to help students learn mathematics by helping them understand why the output is reasonable or by exploring a mathematical idea through interconnected representations, which Drijvers refers to as *learning mathematics*. Buchberger (1990) argued that if students understand how to perform the mathematics being offloaded to technology, it is a use of technology as a *white box*. When that technology performs the mathematics faster and more accurately, Pea (1985) described this use of technology as an *amplification* of human capabilities. If students do not understand the mathematics performed by the technology, Buchberger described this as using the technology as a *black box*. When technology helps students understand a mathematical idea in a new way or grasp an idea they previously did not understand, it is used to *reorganize* the user's understanding (Pea). Cedillo and Kieran (2003) described this use of technology as a *grey box*, illustrating a hybrid of black and white box metaphors.

Instrumental genesis is the progressive development through which a digital artifact becomes a functional *instrument* for mathematical activity, as users construct and stabilize schemes for acting with it (*instrumentation*) while simultaneously shaping the artifact-in-use through selection, configuration, and repurposing (*instrumentalization*) (Vérillon & Rabardel, 1995). In the instrumental approach, an artifact (e.g., a CAS, dynamic geometry environment, or graphing technology) is not automatically an instrument; rather, an instrument is conceived as a coupled system of **(**a**)** the artifact *as used* and **(**b**)** the user's schemes of utilization, recurrent, goal-directed organizations of action that include operational invariants (implicit concepts-in-action and theorems-in-action) and control structures for monitoring and validating results (Rabardel, 1995).

Frameworks for Thinking about Users' Interactions with GenAI

Mollick (2023) conceptualized individuals' relationships with GenAI in the workplace as *centaurs* and *cyborgs*. Working with GenAI as a centaur keeps a sharp boundary between what the human does and what the technology does. Much like the distinct human and horse halves in

the centaur myth. In this approach, responsibilities are deliberately divided so each partner focuses on its comparative strengths, with work handed back and forth as needed. In contrast, cyborg work dissolves the boundary between person and machine by integrating GenAI into the flow of thinking and producing. Rather than cleanly handing off entire tasks, the human and GenAI collaborate in small, iterative exchanges, repeatedly crossing the jagged frontier as one partner begins drafts, phrases, or ideas and the other completes or refines them.

The OECD GenAI Literacy framework (2025) describes four ways students can engage with generative AI: *engaging with AI* (using AI tools while recognizing their presence and evaluating output quality), *creating with AI* (co-producing ideas or products through iterative prompting and refinement), *managing AI* (delegating tasks strategically while retaining human judgment and oversight), and *designing AI* (examining how data and design choices shape model behavior and impacts, oriented toward shaping AI for human good). The United Nations Educational, Scientific, and Cultural Organization (UNESCO) GenAI competency framework (2024) for students treats learning about the technology as preparation for responsible participation in societies, framing students as informed users and, where appropriate, co-creators. It describes four components: human-centered mindset**,** ethics of GenAI**,** GenAI techniques and applications, and GenAI system design. The U.S. Department of Education (2023) frames AI as most valuable when it strengthens human judgment rather than replaces it. For learning, it highlights AI's potential to support more adaptive learning experiences through timely, targeted feedback and guidance (e.g., tutoring systems that respond to students' solution steps), while cautioning that AI models are always partial and must avoid narrow deficit-only conceptions of learning

Equity Issues Surrounding GenAI

Equity concerns about AI in education span the full life cycle of these systems, from the material infrastructure required to build and operate them to the content they generate to how schools and families are positioned to use them effectively. At the infrastructure level, expanding data-center capacity for GenAI can concentrate environmental burdens (e.g., electricity demand and water use) in particular regions and communities, raising questions of resource and environmental justice (Mozur, Satariano, & Rodriguez Mega, 2025).

Metz (2019) highlights the largely hidden, low-paid annotation labor raises fairness, privacy, and embedded-bias concerns. Moreover, generative models can reproduce and normalize historical patterns of bias because they are trained on large-scale internet text and other data that reflect existing social inequalities (Gómez Marchant & Hardison, 2024).

Equity issues also arise from uneven institutional capacity. Recent district survey data suggest that, although many districts anticipate providing professional learning on GenAI, such training is not distributed uniformly, with urban districts less likely to deliver such support during the study period (Diliberti et al., 2024). Finally, student opportunities to benefit from AI are stratified by household resources and dispositions. For example, national survey data indicate that students whose parents have higher educational attainment report more frequent use of GenAI for school and hold more favorable views than peers whose parents have lower educational attainment (Adair et al., 2025).

Framework Gaps

Like other technologies, such as Amplify, GenAI combines both mathematical action/computation infrastructure and conveyance/communication infrastructure. Additionally, in Amplify, content can be communicated between students and the teacher, but in GenAI, content is communicated between a student and the GenAI and from the GenAI to the student. An additional difference between GenAI and previous educational technology is the nature of the

interactions between users and the technology. The lingua franca of prior mathematical action technologies has been mathematical representations, whereas the currency in student-to-GenAI communication is primarily text-based. Additionally, these prior mathematical action technologies could be used to learn mathematics, as Drijvers (2012) has pointed out, but this typically requires working through a predesigned activity, often involving dynamic representations or student freedom to engage with the technology in mathematical ways. GenAI enables users to ask specifically where they are struggling to understand an idea.

Furthermore, non-GenAI forms of technology *constrain* student actions to the functions of the technology (e.g., graphing calculator) or how technology was embedded within an activity structure involving imperatives and questions (e.g., dynamic sketch with constrained student actions); however, GenAI provides users (students within an educational setting) with much more *freedom*. Specifically, GenAI enables users to perform multiple query-response-evaluate cycles, and the query or prompt given to the technology can vary considerably. Thus, the user must examine responses for mathematical fidelity (Dick, 2008) to assess their validity, given the possibility of hallucinations. Furthermore, GenAI users need to reflect metacognitively (e.g., Schoenfeld, 1987) on how well the answer aligns with their understanding and whether it moves them closer to the mathematical learning goal. In general, much has been written about prompt engineering (Qian, 2025), i.e., crafting a query to submit to a generative AI system. Although Mollick (2025) has argued that prompt engineering is less important than it once was, users must still evaluate the GenAI response against their own knowledge to determine whether a further prompt is needed and, if so, what its nature should be. GenAI shares similarities with other Internet-based technologies, such as Google, in that it requires a query, but it differs in that users conducting a Google search may not submit additional queries as they might when using GenAI.

Several frameworks exist for designing and critiquing dynamic manipulatives involving mathematical action technology (e.g., Sherman & Cayton, 2015). Yet at the time of this writing, GenAI cannot create dynamic, manipulative sketches. Hence, while GenAI expands the capabilities of mathematical action and conveyance technologies, it is limited in other ways. Consequently, frameworks associated with the dynamic capabilities of mathematical action technology were excluded from the framework presented here.

In their examination of frameworks for learning and teaching mathematics with technology, McCulloch et al. (2021) identified three gaps in existing frameworks: equity, noticing student thinking, and discourse. Equity and access should be treated as an explicit framing rather than an afterthought: the authors note that equity concerns are often not directly addressed across the sampled frameworks, even though technology-access criteria (e.g., what devices, accounts, connectivity, and policies are available) routinely determine what can be used in practice. In a GenAI-oriented framework, this means positioning access constraints, such as account availability, platform restrictions, bandwidth reliability, and data/privacy policies, within the technological strand itself and treating them as design constraints that shape pedagogical intent.

McCulloch et al. (2021) emphasize that noticing changes in student thinking during technology-mediated activity is challenging: when students use mathematical action technologies, evidence of their thinking is often embedded in tool interactions, creating a need for explicit guidance on what counts as evidence and how it should inform instruction. For GenAI, the conversational trace, prompts, follow-up questions, revisions, and corrections can become a rich resource for noticing, but only if teachers and students have a shared interpretive language (for example, distinguishing verification from delegation, or identifying moments of conceptual repair).

Finally, McCulloch et al. (2021) position classroom discourse as a central object rather than a peripheral concern, highlighting that discourse is another underdeveloped intersection and that technology can reshape how students justify, argue, and coordinate meanings. A GenAI-specific implication is that discourse now includes a non-human conversational partner; therefore, a framework should specify when and how this new discourse supports justification and argumentation, and how the classroom establishes shared criteria for what counts as a good justification.

GenAI as a Mathematical Learning Tool: Proposed Analytical Framework

Although the nine dimensions described below arise from distinct sources, they are unified by an organizing principle, the distribution of epistemic agency across the student-GenAI-classroom environment. Unlike previous mathematical action technologies, whose mathematical fidelity was a design property, GenAI is a fallible conversational partner, in which the location of mathematical authority is negotiated during each interaction. Each dimension examines a facet of this negotiation. The conditions under which students are positioned to exercise agency (Dimension A), the enactment of agency in positioning the tool, verifying its output, justifying claims publicly, monitoring one's own understanding, and using the tool in ethically informed ways (Dimensions B-G), and the visibility and consequences of that agency in the conversational trace and the final mathematical product (Dimensions H-I). In this way, the upper levels of each dimension describe a student who retains intellectual autonomy (Yackel & Cobb, 1996) in partnership with the technology, while the lower levels describe authority, delegated by default or design, to GenAI.

Unit of Analysis

I define an *episode* as a single problem or task from initiation through completion and reflection, comprising both student work and the GenAI conversational trace, including the student's prompts to the system and the technology's responses. A *turn/move* consists of a student prompt and a GenAI response. Space constraints prevent me from providing all the details of the analytical framework. Instead, I present the framework's dimensions and subdimensions. Dimensions A, B, F, and G are descriptive in nature with no increase in sophistication among the subdimensions, while Dimensions C, D, E, H, and I are developmental, showing increased sophistication from lower to upper levels.

Dimension A: Equity and Access as Design Constraints

Following McCulloch et al. (2021), the first construct encompasses equity and access as design constraints. This construct assesses whether access and policy realities are treated as explicit constraints that shape the learning pathway. It consists of three subdimensions. The first is material/platform access, which includes the type of GenAI used (free or paid), school bandwidth features, and school-level blocked features. The second is privacy constraints, which involve what can and cannot be entered into the AI and the norms governing anonymization. The third is institutional support capacity, which involves the availability of guidance, norms, prompt templates, and training. Each of these subdimensions is coded across four levels: unarticulated, noted, planned around, and strategically leveraged and documented. Some of these subdimensions measure components at the school and episode levels, specifically what students have been taught to develop prompts.

Dimension B: GenAI Function and Instrumentalization in Mathematical Activity

This dimension captures how students shape GenAI as an artifact-in-use. It codes the role the student assigns to GenAI and the ways the student configures that role through prompts, constraints, and iterative reconfiguration. It does not code learning outcomes or quality of

mathematical reasoning. It codes the intended tool role and configuration moves, regardless of whether they succeed. The first category involves an answer-retrieval role, in which the GenAI is positioned as a source of answers. In the second category, the student positions the GenAI in a procedure generation role. In the third category, GenAI is positioned in an explanation/representation-provisioning role, regardless of whether the student learns from their interactions. The last category involves an inquiry-orchestration role in which the student iteratively reconfigures GenAI, for example, by examining the effects of a parameter on a graphical representation. This last category aligns with Mollick's (2023) metaphor of work with the GenAI as a cyborg.

Dimension C: Epistemic Control and Verification

This category refers to correctness that is established through mathematical validation rather than GenAI authority. This category aligns with the OECD (2025), which asks students to engage with the outputs of GenAI; UNESCO (2024), which positions students as important arbiters of the validity of GenAI results; and the U.S. Department of Education (2023), which emphasizes strengthening human engagement rather than replacing it. There are four subdimensions within this dimension. In the lowest level, students do not verify the GenAI response, and there is no control structure with authority delegated to the technology. The next subdimension is weak/fragile control, in which students may ask the GenAI system questions in different ways but use its responses as their own without critically examining them. The third subdimension involves the student performing a form of mathematical work (e.g., estimation) to assess the validity of the GenAI answer, thereby demonstrating some degree of control. Within the last subdimension, students may evaluate the response in multiple ways and correct the GenAI response when it is incorrect, thereby demonstrating robust control.

Dimension D: Classroom Discourse and Justification with a Non-human Partner

This dimension addresses the gap in the previous technological frameworks identified by McCulloch et al. (2021) and the fact that in a GenAI environment, students engage in conversation with a non-human partner. The dimension comprises two subdimensions: the role of GenAI in discourse and the norms governing what counts as valid justification. There are four components of GenAI's role in discourse. 1) Proxy discourse where the GenAI provides reasoning. 2) Assisted discourse consists of paraphrasing the GenAI response and limited warrants. 3) Dialogic support consists of the student using the GenAI to test and refine while the student author warrants. 4) Argumentation environment consisting of warrants, rebuttals, and definitions, with GenAI playing a role, strengthens reasoning under classroom norms.

There are four subdimensions under norms. 1) Unspecified, where the student states that the GenAI agrees. 2) There are partial or inconsistent norms. For instance, a student may ask why but receive only a procedural explanation or ask a peer for an explanation but accept a GenAI response without making the same request. 3) Explicit criteria are used, consisting of definitions, warrants, validity checks, and representation coordination. 4) Under enforced or shared criteria, students critique GenAI and peers using agreed standards. The key is not just that criteria exist, but that they are collectively enacted. Students actively police their own arguments and revise them, including those generated by GenAI, until they meet the standards.

Dimension E: Noticing and Metacognitive Reflection

This dimension relates to the importance of metacognition (Schoenfeld, 1987) in interacting with GenAI while students work on a mathematical task. An important precursor to reflecting is noticing. Additionally, it highlights the importance of students reflecting on their work involving GenAI (OECD, 2025). There are four subdimensions within this dimension. First, students may

exhibit no reflection on an episode involving the GenAI. Second, students may provide only vague reflections, such as "I get it now." Third, the student identifies the misconception, insight, or shift in understanding, and describes how working with GenAI led to that change. Fourth, the student identifies a general strategy and applies it to a case related to the problem initially addressed using the technology.

Dimension F: Life-cycle Equity Awareness and Enactment

This dimension captures the equity issues across the GenAI lifecycle, as outlined above. The first subdimension concerns infrastructure/environmental burdens associated with GenAI. A student who recognizes this does not merely acknowledge the risks; they adjust their use of the technology to limit their interactions. The second subdimension involves understanding hidden labor, accountability, and privacy risks. For example, the student does not upload a photo of their quiz with their name on it; instead, they write out the steps associated with the quiz to receive feedback on those steps without jeopardizing their privacy. The third subdimension recognizes the bias associated with the use of GenAI in providing context for a mathematical idea (Gómez Marchant & Hardison, 2025) or in overgeneralizing a mathematical procedure. The last subdimension involves an opportunity to benefit from stratification, where the student understands and explicitly states that they have access to the paid version of a GenAI system, which provides them with more capabilities than their classmates, who only have access to a free version.

Dimension G: Instrumentation Effects and Technology Mediation

This dimension captures the mediated effects of GenAI on the student's mathematical activity and thinking. The first subdimension captures whether GenAI's involvement orients the episode toward doing mathematics (offloading/producing answers) versus learning mathematics (sense-making, explaining, connecting representations), consistent with the doing/learning distinction (Drijvers, 2012). The second subdimension examines how GenAI-mediated work affects the transparency of mathematical reasoning, drawing on black box, white box, and grey box perspectives (Buchberger, 1990; Cedillo & Kieran, 2003). The coding here is based on the student's own mathematical account and monitoring, not on the level of detail in GenAI's explanation. The last subdimension captures whether GenAI primarily amplifies performance (e.g., speed, formatting, reduced cognitive load) or reorganizes understanding (e.g., new representation, new schema, new connections), consistent with amplification/reorganization (Pea, 1985).

Dimension H: Trace-based Noticing of Student Thinking

This dimension examines the extent to which the GenAI conversational trace is interpretable as evidence of student thinking (subdimension H1) and whether teachers and students have a shared language to examine conversations between the student and the GenAI (subdimension H2). It addresses a gap identified by McCulloch et al. (2021) while aligning with the OECD (2025) by engaging with GenAI to evaluate output quality and to create with GenAI. Subdimension H1 contains four levels. The first level corresponds to thin or one-shot interactions, such as when a student asks for an answer, and the GenAI responds with it. At the second level, GenAI provides procedures for the student to verify. At the third level, the student shares steps with the GenAI, requests verification of these steps, and, if there is a mistake, works with the technology to determine the source of the error. In the final level, the GenAI and the student each propose steps and solutions to solve a problem, with the student ensuring they understand the technology's responses.

Subdimension H2 contains four levels: none, basic labels, shared distinctions, and instructional actionable. At the lowest level, the teacher notes that the student used ChatGPT, but there is no further parsing of how the student used GenAI. At a basic label level, the student states that they used GenAI for help, and the teacher responds with, "So, you got the steps from AI." The terminology used by the teacher and the student describes how GenAI was employed to solve a problem. For instance, the student may state that this part of the work was *delegated* (where the GenAI completed the algebraic manipulation for the student). In the final level, common terminology is used to determine the next set of interactions between the student and the GenAI, which are teacher-directed and interpreted by the student.

Dimension I: Mathematical Integrity of the Final Product

The last dimension examines the quality of the final mathematical product (solution and explanation) independent of GenAI authorship. This dimension differs from dimension C, which examines how correctness is established. Dimension I differs from dimension E, which examines how the student articulates changes in their understanding. Finally, this dimension differs from dimension G, which examines how GenAI mediates mathematical work. There are four levels to dimension I: (1) incorrect/unsupported, (2) partially correct, (3) correct with adequate justification, and (4) correct, justified, and communicatively strong (coherent, clear, and anticipates conditions/objections).

Illustrating the Framework

Maya, an Algebra 1 student with school-provided access to a free GenAI system (Dimension A), types a quadratic equation into the system rather than photographing the work and submitting that to the system, consistent with classroom privacy norms (Dimension F). She prompts, "Show me how to solve $x^2 - 6x + 2 = 0$ by completing the square and explain each step (Dimension B, explanation-provisioning role). The GenAI response contains a sign error. Maya substitutes the proposed root into the original equation, finds it fails, and prompts, "Check step 3. I think $(x - 3)^2$ gives +9, not –9." The technology provides a corrected response, which she verifies (Dimension C, robust control; H1, level 3, an interpretable trace of error-locating work). Asked to reflect, Maya writes, "It makes sense now" (Dimension E, vague reflection). The next day she tells her group, "the AI showed me," without stating the warrant herself (Dimension D, assisted discourse). Maya's solution is correct with adequate justification (Dimension I, level 3). In the episode, GenAI mediates learning rather than offloading (Dimension G, doing mathematics, white box). Maya exercises strong epistemic control privately while ceding authority publicly, illustrating the power of combining verification and discourse in the framework.

Conclusion

This analytical framework is an initial attempt to capture the capabilities of GenAI as a mathematical learning tool for students. It builds on prior frameworks, addresses gaps identified in them, such as a lack of equity, incorporates components from international competency frameworks around GenAI (e.g., OECD, 2025), and includes capabilities specific to GenAI. While this framework is GenAI-specific, it does not cover all GenAI capabilities, such as agentic AI, which refers to systems that can perform their own tasks with minimal supervision. GenAI is transforming rapidly, and as Mollick (2024) has written, "…whatever AI you are using right now is going to be the worst AI you will ever use" (p. 61). Consequently, any GenAI framework is likely to be revised; however, it provides a foundation on which others can build or renovate as needed. The unique natural-language interaction currently required of users suggests that mathematics educators may need to work with literacy specialists to analyze how students use GenAI to deepen their understanding and where they may struggle with this math learning tool.

INTEGRATING COMPUTATIONAL THINKING IN ELEMENTARY MATHEMATICS: COMPARING TEACHER INTENTIONS AND RESEARCHER INTERPRETATIONS

Terrie M. Galanti
University of North Florida
terrie.galanti@unf.edu

Zuhal Yilmaz
North Carolina State University
zyilmaz@ncsu.edu

This study examines how elementary teachers conceptualize the depth of computational thinking (CT) integration in mathematics lessons they design. Eleven teachers enrolled in a graduate STEM education program course designed standards-aligned mathematics lessons incorporating coding. They categorized the level of CT integration with an exist-enhance-extend integration (Waterman et al., 2020). Using deductive content analysis, we analyzed the lesson designs and compared our categorizations with teachers' self-categorizations. Findings suggest that teachers often associate integration depth with the presence of code rather than opportunities for mathematical reasoning. Implications for professional development include explicitly supporting teachers in leveraging iteration, parameter variation, and modeling to deepen conceptual understanding of mathematics through computing.

Keywords: Computational Thinking, Computing and Coding, Elementary School Education, Professional Development

With the growing recognition that computational thinking (CT) is a cross-cutting skill that is best developed in STEM learning contexts (Grover, 2021), the mathematics education community has a timely opportunity to change perceptions of mathematics as procedures, skills, and facts that have been known for decades or even centuries (Li & Schoenfeld, 2019). There is a natural overlap between CT and mathematics in relation to abstraction, generalization, and modeling. (Silva et al., 2020; Strickland et al., 2021; Weintrop et al., 2016). This "mutually supportive potential of computing and mathematics" (Weintrop et al., 2022, p. 39) has only begun to be explored in elementary education (Wu & Yang, 2022).

CT in the form of coding can be an especially powerful medium for developing conceptual understanding of mathematics (Boote & Galanti, 2023; Ye et al., 2023). Yet efforts to integrate CT into school curricula remain largely compartmentalized, and teachers have limited opportunities to build their own confidence in learning and teaching coding (Mills et al., 2025). Most coding activities in elementary grades are not aligned with content standards or are taught as a standalone subject (Kakavas & Ugolini, 2019). When elementary teachers learn to facilitate students' use of computing as both a process and product of dynamic mathematical thinking (Cui et al., 2023; Dahshan & Galanti, 2024; Galanti, 2022, Weintrop et al., 2016), they can leverage the natural overlap between CT and mathematics for deeper learning.

Recent research on the preparation of elementary educators to leverage CT as a vehicle to enrich students' exploration of mathematical patterns and structure has largely focused on preservice teacher education (e.g., Dobgenski et al., 2025; Gleasman & Kim, 2020). There is also a need to understand how experienced elementary teachers perceive the integration of CT and mathematics learning in their own lesson designs. These insights can in turn inform more relevant professional development experiences that build teachers' abilities to integrate CT for the purpose of deepening mathematics learning (Kotsopoulos et al., 2019).

This vision for computing-integrated mathematics teaching and learning will not be realized without the development of teacher capacity to both design and facilitate these experiences

(Kong et al., 2020). This study focuses on elementary teachers' categorization of the level of CT integration in mathematics activities. The following research questions guided our study:

1. How do elementary teachers enrolled in a graduate-level CT course categorize the depth of CT integration in mathematics lesson design assignment with a coding component?
2. What similarities and differences emerge in how teachers and researchers interpret and apply an exist-enhance-extend framework (Waterman et al., 2020) when describing the depth of CT integration in mathematics lesson designs?

Theoretical Perspectives

While there is still no scholarly consensus on the definition of CT (Cansu & Cansu, 2019), there is general agreement on its close connection to the process of problem solving. CT has specific characteristics related to problem formulation; organization and analysis of data; use of abstractions such as models and simulations; efficiency of algorithmic solutions; and generalizability of solutions (International Society for Technology in Education & Computer Science Teachers Association, 2011). CT integration can emphasize both computing skills (e.g., sequencing, loops, conditionals, debugging) and learning processes (e.g., communication, creativity, exploration/engagement) (Israel & Lash, 2020). Students often learn mathematical concepts by memorizing procedural approaches with limited opportunities for logical thinking. Well-designed CT activities encourage students to make sense of mathematical concepts beyond procedural memorization and apply computational strategies to representing and deepening their mathematical sensemaking (Wang et al., 2022; Weintrop et al., 2016).

CT integration has potential to increase the depth of mathematical learning in PK-12 classrooms (Hjalmarson et al., 2020; Rich et al., 2020), but there is a need for evidence-based professional development experiences to build this CT integration capacity (Bull et al., 2020; English, 2018). Yeni and colleagues (2024) offered several recommendations for teacher professional development on CT integration, including an emphasis on lesson design aligning subject matter and computational principles. They also highlighted the value of collaboration between teachers and researchers to scaffold CT knowledge and to select an appropriate level of CT integration.

Most of the research on levels of CT integration in K-12 has taken a technology-centric approach by adapting Puentedura's (2011) Substitution, Augmentation, Modification, and Redefinition model. In this conceptualization, depth progresses from subject-specific and low-tech substitution and augmentation to more transformative, interdisciplinary transformation (Yeni et al., 2024). Grover's (2021) CTIntegration framework, informed by Kohler and Mishra's (2007) TPACK principles, focuses on teacher knowledge for design of K-12 CT integrated learning. This framework includes the subject domain and computing as distinct but overlapping fields informed by content, practices, and pedagogies in each of these fields. The application of this framework to examine the development of pedagogical knowledge for CT integration in teacher professional learning has elicited the tensions between teachers computing knowledge and their readiness to integrate CT into practice (Lane et al., 2023).

Waterman and colleagues (2020) conceptualized three levels of CT integration in the specific context of elementary mathematics and science education. This *exist-enhance-extend* framework has been applied to adapt existing district curriculum to develop CT skills and practices (Waterman et al., 2020) and to analyze teacher lesson design and implementation (Coenraad et al., 2022; Nolte et al., 2024). While prior research on this framework has focused on the assessment of existing curriculum or teacher-generated lesson plans, we see the important

potential to use these ideas in the design of professional development. By using the *exist-enhance-extend* framework as both an instructional resource and a reflective tool in professional development, teachers can build their capacity to integrate CT with intentionality in mathematics instruction.

In the paragraphs that follow, we elaborate on our conceptualization of the Waterman et al. (2020) framework in the specific context of elementary mathematics education.

Adaptation of Waterman's (2020) Framework for Levels of CT Integration in Mathematics

At the *exist* level, teachers may draw attention to CT concepts, skills, and practices that are embedded within mathematics instruction. Common mathematical practices such as decomposing a problem into steps, following and evaluating algorithms, or recognizing patterns, can be intentionally described as CT. For example, when students follow a standard procedure for solving an equation, the teacher may highlight this process as an algorithm and discuss how similar step-by-step instructions are required for a computer to perform calculations. No new tasks or technologies are required at this level; rather, the teacher highlights how CT is already present within a mathematical activity.

At the *enhance* level, teachers may add tasks or tools that support existing mathematics instruction without changing the mathematical questions students are asked to answer. Computing may be used to make problem solving or investigations more efficient, but tools do not necessarily create new opportunities for mathematical exploration. For example, students might program a computer to recreate a graph they have already made by hand or to create representations they will interpret using previously learned strategies. In these cases, engaging in CT practices such as abstraction, pattern recognition, and debugging may deepen students' mathematical understanding.

At the *extend* level, opportunities for mathematical reasoning are fundamentally changed because of the integration of computing. Teachers may design programming activities in which students can explore and apply mathematical concepts in ways that would not be possible without a computer. Students learn mathematics and CT more deeply in a mutually beneficial way (Weintrop et al., 2022) by creating, testing, and refining computational models of mathematical ideas. For instance, students might write programs to model multiplication as repeated addition or simulate probabilistic events. They might translate mathematical relationships into algorithms and debug their reasoning when results do not match expectations. These experiences extend mathematics instruction beyond traditional representations, positioning students to engage with mathematics as a dynamic, computationally mediated discipline.

Coenraad and colleagues (2022) suggested "exhibit" as a fourth level of CT integration based on their analysis of practicing teachers' CT-integrated science lessons. This level is characterized by the use of block-based programming to animate a science concept. Since the integration of programming only served as a way of presenting knowledge and not as a way of deepening science learning, it did not fit within any of the three established levels.

Although the exist-enhance-extend framework provides shared terminology for describing the depth of CT integration, exposure to this framework in professional learning does not necessarily ensure shared conceptualizations of what constitutes meaningful integration. Teachers and researchers may bring different assumptions informed by prior beliefs and experiences with mathematics, computing, and curriculum. For example, teachers may emphasize the presence of code, while researchers may focus on how computing deepens opportunities for mathematical reasoning. Examining how teachers interpret and apply CT

integration frameworks in comparison with researcher interpretations can inform professional learning and better support teachers in leveraging CT for mathematical sensemaking.

In this study, we chose to employ the "*exist-enhance-extend*" framework as a structure for lesson design, teacher reflection, and research analysis. With these multiple perspectives, we sought to understand the ways in which teachers might perceive CT integration differently than mathematics education researchers.

Methods

In a Summer 2025 synchronous online CT course for elementary teachers who were enrolled in a STEM+C graduate certificate program, teachers (n = 11) collaboratively explored the relationship between CT and mathematics learning in a series of instructor provided mathematics tasks integrating both unplugged and plugged CT approaches (e.g., BeeBots and Scratch block-based programming). As part of their reflection on their experience with these tasks, teachers analyzed CT concepts and practices (Grover & Pea, 2018) and the Standards for Mathematical Practice (NGA & CCSSO, 2010) for conceptual overlap.

The unit of analysis for this study was the CT-integrated mathematics lesson design created by teachers during Week 7 of the 12-week course. Prior to creating their lessons, teachers read two chapters from *Computational Thinking in Pre-K: Empirical Evidence for Integration and Future Directions* to learn about levels of CT integration in Grade 5 science lessons (Coenraad et al., 2022) and CT integration in Grade 4 mathematics (Weintrop et al., 2022). Teachers also researched an integrated CT lesson from the freely available Digital Promise library. They categorized the level of CT integration in their chosen lesson using descriptions of *exist*, *enhance*, and *extend* levels of CT integration. They further reflected on how they would teach the relevant subject area differently because of the CT integration.

For the integrated CT and mathematics lesson design assignment, teachers were prompted to design a mathematics activity (30–45 minutes) that emphasized the Standards of Mathematical Practice, CT, and coding. In the activity planning template, they were provided with a set of design scenarios to illustrate varied levels of CT integration. In addition to identifying relevant CT components (pattern recognition, abstraction, decomposition, and algorithms) and programming skills (iterative development, debugging) in their activities, they categorized the level of CT integration using the *exist-enhance-extend* framework.

The lesson design template also included a Launch-Explore-Summarize model structure that supports inquiry and mathematical sensemaking. Teachers had the choice of what coding tools to integrate. Two of the teachers integrated Bee-Bots in Grade K-3 mathematics lessons, while the other nine teachers integrated Scratch in Grades K-5 lessons. All teachers who integrated Scratch used starter code provided by the instructor or from CT education websites.

Using a deductive content analysis approach (Elo & Kyngäs, 2008), we collaboratively classified the lesson design artifacts using the levels of CT integration as apriori codes. The first author, the course instructor, initially assigned a CT integration level to each of the lesson designs, using both the template content and the formative feedback that she provided when she graded the assignments to support her inferences. She assigned her level based on lesson text coupled with identifiable entry points to deepen either CT or mathematical reasoning within the lesson design. The second author independently assigned integration levels. Finally, we collaboratively discussed our categorizations, comparing them to the teachers' categorizations to identify patterns and emergent themes. Trustworthiness was supported through collaborative coding, consensus-building discussions, and documentation of our interpretations.

Results

We identified five distinct patterns in teacher and researcher categorizations of CT integration (see Table 1). Our categorizations of the levels of CT integration agreed with teachers' categorizations in five of the 11 lesson designs, with two cases of agreement at the *enhance* level and three cases of agreement at the *extend* level.

Table 1: Patterns of Alignment Between Teacher and Researcher Categorizations of CT Integration

Teacher	Researcher	Number of Lessons
Enhance	Enhance	2
Extend	Extend	3
Enhance	Exhibit	2
Exist	Potential to Enhance	1
Enhance	Potential to Extend	3

In the other six lesson designs, three additional patterns emerged. We found two cases of teachers planning to use code for students to display mathematical knowledge and four cases of teachers understating the integration potential of coding for mathematics learning. Across these four cases, we found differences in teachers' descriptions of their mathematics learning goals and the potential for deepening conceptual understanding of mathematics through coding.

In the sections that follow, we highlight cases from three different mathematics domains to surface how teachers designed lessons at different levels of integration and to highlight how teachers might understate the mathematical power of computational integration.

Grade 3 Number and Operations Lesson (Enhance → Potential to Extend)

In this mathematics lesson, Caryn (Grade 3 teacher) described her learning goals as reinforcing number patterns and fact fluency through coding. She planned to prompt students to create a "Multiplication Machine" in Scratch that would model multiplication by taking two numbers as input and displaying the product. She classified the level of CT integration as *enhancing* their mathematics learning by "showing their understanding of multiplication as a process as they combine programming to compute how to multiply." She emphasized her motivation to use the "Multiplication Machine" to increase students' multiplication fact fluency.

Caryn also provided a link to an instructor-provided Scratch project (see Figure 1) automating the generation of multiplication facts with meaningful variable names, understanding of counting by one, and skip counting by three in expressing sequences of multiplication Students could also apply their understanding of multiplication tables to generate sequences of products. However, this code was not explicitly integrated in her planned lesson enactment.

Caryn's expectations for her students did not leverage opportunities to demonstrate conceptual understandings of multiplication through coding. In the Launch phase of her lesson design, she planned to model the coding for the "Multiplication Machine" in a different way than in the coding project she referenced. She would show her students how to use four blocks of code to input two numbers and multiply two numbers to display a product. She would then release her students to work in pairs to create their own projects.

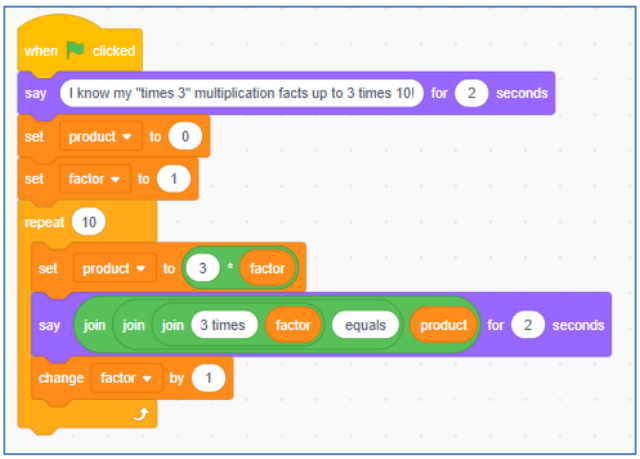

Figure 1: Instructor-generated Scratch Project Modeling Multiplication Patterns

We described the CT integration potential within this lesson as *extending* because of the opportunities to explore multiplicative patterns and structure through repetition. In lieu of a demonstration of code as a calculator for isolated multiplication facts, Caryn could provide students with a subset of the blocks in the instructor's example project. With purposeful scaffolding, students could then connect coding to reasoning about patterns in multiplication. They could also create equal groups with linking cubes, number lines, or rectangular arrays to connect the functionality of their code to multiplicative structure and patterns. This emphasis on iteration as a CT skill and connections to mathematics representations within Caryn's lesson design would raise the integration potential from *enhancing* to *extending*.

Grade 4 Geometry Lesson (Enhance → Potential to Extend)

Paula's Grade 4 "Drawing Polygons with Code" lesson supported her learning goal of understanding the relationship between angle measurements and polygons. She classified the level of CT integration as *enhancing* mathematics learning because students were measuring angles and connecting angles to turn in their code. During the Launch phase of her lesson, she planned to introduce her students to the concept of exterior angles and model how knowledge of exterior angles could be used to draw a square in Scratch coding. During the Explore phase of the lesson, students would use protractors to measure exterior angles on other polygons and then modify the square drawing Scratch code (See Figure 2) to create regular triangles, pentagons, hexagons and octagons. Paula also planned to lead a whole class conversation about the shapes that the students made and how they debugged their code to draw their shapes.

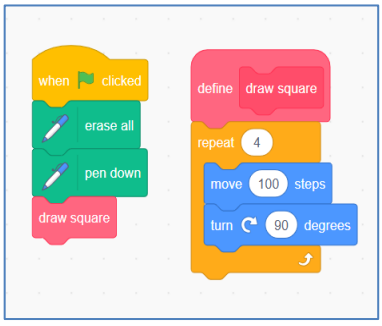

Figure 2: Instructor-generated Scratch Project Modeling Shape Patterns

Because students are modifying the repeat parameters and the amount of turn in the starter Scratch project, they can understand angle not only as a static quantity to be measured with a protractor but also as units of rotation. Because the actions in the code can deepen students' concept of angle and make more advanced geometry concepts (e.g., interior and exterior angles, transformations) more accessible, we classified the CT integration potential in this lesson as *extending*. We noted that in Paula's lesson design, some students might simply replace the amount of turn in the coding block with the exterior angle they measured on the worksheet without understanding the concept of rotations. Paula could make use of paper plate spinners, pattern blocks, or physical motion to scaffold these connections.

Grade 3 Patterns and Data Lesson (Extend → Extend)

Laine integrated both Scratch coding and Excel spreadsheet formulas in her "Pattern Detectives" lesson. Her goal was for students to learn to model arithmetic patterns through code, test pattern rules, and interpret real-world data trends in tables and graphs. Her opening question was "Can a computer recognize patterns like you can?" She provided a starter Scratch project in the Launch phase of her lesson and prompted pairs of students to modify the parameters in the Scratch project to create repeating number patterns. She would later contrast these experiences with predictable, automated patterns (constant differences) with the natural patterns and trends that they might find in real-world weather patterns (varying differences). The teacher would model the use of subtraction formulas in the Excel spreadsheet to evaluate varying differences. Her description of the depth of CT integration connected these two computing opportunities.

Laine categorized her lesson as *extending* the mathematics concepts by integrating programming and spreadsheet tools to explore patterns in data over time. Rather than just identifying patterns on paper, students would use Scratch to simulate numerical sequences and spreadsheets and analyze real-world data, applying CT practices like abstraction, debugging, and automation.

We also described the purposeful pairing of generating patterns in Scratch programming and looking for patterns in temperature data as *extending* the mathematics learning opportunities. Laine's sequencing of pattern explorations created opportunities for rich conversations about constant differences and varying differences from one data point to the next. We also noted that Laine's students could also use the Excel spreadsheet to plot the data from the Scratch project alongside the weather data, creating rich conversations about patterns and sequencing.

Discussion and Implications

Our analysis of teachers' categorizations of the interplay between CT and mathematical sensemaking revealed variation in the ways that teachers saw the purpose of code and how it related to mathematics learning. Several teachers seemed to categorize their CT integration as *enhancing* mathematics learning because students could see mathematics concepts through code. In Caryn's case, we wondered if she perceived coding as a means of making mathematics more engaging as opposed to deepening conceptual understanding of multiplication. She did not seem to see code as a tool for reasoning about mathematical relationships beyond efficient calculation of answers. In contrast, our categorizations focused on how coding might deepen opportunities to model mathematical structure, vary mathematical parameters, and reason about patterns in new ways. These categorizations are consistent with prior research on how CT practices can serve as productive entry points into mathematical reasoning about structure and generalization (Silva et al., 2020; Yilmaz et al., 2024; Wang et al., 2022).

We also noted how expressed learning goals for the lesson related to teachers' categorizations. Caryn and Paula were focused on coding to achieve mathematical products of

calculating multiplication expressions and drawing shapes correctly. We as researchers saw the potential for exploring patterns and rotations through the process of coding. Laine used her students' experiences with coding numerical patterns to build a conceptual foundation for her learning goal related to investigating patterns in real world data. In her case, the code opened the door to more meaningful mathematical conversations. Across all three cases, we envisioned ways in which physical or graphical representations coding output could create further opportunities for reasoning about mathematics through coding.

Prior application of the *exist-enhance-extend* framework for CT integration has focused primarily on researcher analysis of lesson design and enactment (Coenraad et al., 2022; Nolte et al., 2024). In our study, the framework functioned simultaneously as an instructional tool, a reflective scaffold for teachers, and an analytic tool for researchers. This positioning surfaced differences in how teachers and researchers conceptualized the same lesson designs. Teachers often emphasized coding and engagement, while researchers more often focused on opportunities for mathematical modeling, parameter variation, and conceptual reasoning. These differences are best understood as entry points for professional learning design. Making these differing interpretations explicit may help mathematics teacher educators better scaffold teachers' noticing of how coding can deepen mathematical understanding. At the same time, researchers can learn from teachers' practical perspectives on feasibility and classroom enactment when designing CT-integrated learning experiences.

As mathematics teacher educators who are excited about the potential realizing the mutual benefits of CT and mathematical thinking in elementary classrooms, we have new questions about how to better scaffold teachers' facilitation of deep mathematical learning through code. We recognize that we need to do more than offer coding experiences and a library of starter Scratch projects tied to elementary mathematics content standards. Consistent with Grover's (2021) CT Integration framework, teachers' realization of CT integration potential may be as much of a reflection of the depth of their mathematics knowledge for teaching as it is of the depth of their knowledge of coding. Distinguishing between using code as a more engaging way of doing mathematics and using computing to model mathematical ideas should be an explicit focus in teacher professional learning. Articulating a learning goal that emphasizes how CT skills and practices can deepen explorations of mathematics concepts is also critical to realizing the integration potential.

The juxtaposition of teachers' and researchers' interpretations of CT integration frameworks in this study advances knowledge about the design of professional development for elementary teachers. Future research on teachers' use of the *exist-enhance-extend* framework for CT integration should focus not only on lesson design artifacts but also on enacted classroom instruction. By examining the differences between intended and enacted CT integration, mathematics teacher educators can more productively support teachers in leveraging coding not merely as an engaging activity but as a vehicle for deepening students' mathematical sensemaking.

As generative artificial intelligence (GenAI) reshapes higher education, undergraduate mathematics faculty face new questions about integrating it into instruction. This mixed-methods study examines how 41 faculty describe their GenAI experiences using a framework integrating the Technology Acceptance Model and the Will, Skill, Tool model. We collected concurrent Likert-scale and open-ended survey data. Results indicate that faculty are generally open to implementing GenAI into teaching but report low confidence and institutional support needs. Even among those who have already redesigned aspects of their teaching, hesitancy remains due to concerns at the individual, student, and institutional levels.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Teacher Beliefs; Teacher Noticing; Technology

Introduction and Literature

With a rapid emergence of generative artificial intelligence (GenAI) since 2022, teaching and learning have been impacted across disciplines and educational levels in various ways. While GenAI offers personalized, adaptive feedback that can benefit students and teachers (Pardos & Bhandari, 2024; Wardat et al., 2023), concerns persist around inaccurate outputs, overreliance, and academic integrity (Lim et al., 2023; Michel-Villarreal et al., 2023; Yoon et al., 2024).

In secondary mathematics, it has become increasingly common for students to use GenAI (Kasneci et al., 2023). Some studies reported that GenAI benefits them. For example, middle school students treat GenAI as a learning companion and facilitator, rather than merely an answer machine, resulting in larger improvements in their mathematical knowledge (Song et al., 2024; Xing et al., 2025). Wu et al. (2024), through their mathematics classroom experiment, found that high school students who used ChatGPT outperformed those who did not use it. However, other studies reported contrasting findings. Bastani et al. (2025) found that when high school students used ChatGPT, they often relied on complete solutions, which hindered skill development. Moreover, researchers have pointed out that K-12 students do not often recognize or understand the ethical issues related to using AI (Gouseti et al., 2025).

In undergraduate mathematics, GenAI presents both opportunities and unique challenges compared with secondary education given the more abstract and rigorous content. Regarding opportunities, Pardos and Bhandari (2024) found that ChatGPT-generated hints produced greater learning improvements than no assistance or human tutoring, while Gouia-Zarrad and Gunn (2024) reported improved coding skills and engagement when students used ChatGPT in a differential equations course. Liu et al. (2026), in a meta-analysis of 22 empirical studies, reported a moderately positive impact on learning outcomes. However, Wang et al. (2024) found that extensive AI use widens the gap between AI-supported performance and actual mastery, as students are less likely to internalize concepts. Similarly, Yoon et al. (2024) and Klawa et al.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

(2025) noted that students often accept AI responses without critical evaluation and struggle to balance AI assistance with the cognitive demands of proof construction.

Based on our review, research on undergraduate mathematics faculty use of GenAI remains limited compared to the studies focused on students. To address this gap, this study explores undergraduate mathematics faculty experiences and perspectives on GenAI use, guided by the research question: How do undergraduate mathematics faculty perceive GenAI integration?

Theoretical Framing

This study is guided by two complementary theoretical frameworks: the Technology Acceptance Model (TAM; Davis, 1989) and the Will-Skill-Tool model (WST; Petko, 2012). The TAM emphasizes two key beliefs shaping technology integration: perceived usefulness (PU), the degree to which users believe technology improves performance, and perceived ease of use (PEU), the degree to which users believe technology requires minimal effort (Venkatesh & Bala, 2008). WST outlines three conditions for successful technology integration: Will (teachers' motivation, attitudes, and beliefs), Skill (teachers' technical and pedagogical competence), and Tool (access to technology, infrastructure, and institutional support), all of which must be present simultaneously.

Eight Attitude Dimensions (Table 1)

Based on TAM and WST, we identified eight attitude dimensions (Joung et al., 2026): (a) Openness/Curiosity (TAM's PU), reflecting faculty interest in GenAI's teaching potential; (b) Student Impact Concerns (TAM's PU), capturing faculty beliefs about GenAI's effect on student learning; (c) Integration Confidence (TAM's PEU), reflecting faculty belief that GenAI integration will be manageable; (d) Traditional Methods Preference and (e) Curriculum Modification Willingness (WST's Will), capturing faculty motivation toward or resistance against changing established practices; (f) Equity/Access Concerns (WST's Will and Tool), reflecting faculty values about fairness and equitable resource access; (g) Institutional Support Needs (WST's Tool), encompassing required training, policies, and infrastructure; and (h) Professional Practice Influence (TAM's actual system use and WST's integration success), capturing behavioral changes associated with faculty attitudes. This framework guided survey development and served as an analytic lens for our study.

Table 1: Eight Attitude Dimensions Aligned with TAM and WST Frameworks

Study Dimension	TAM Alignment	WST Alignment
1. Openness/Curiosity	Perceived Usefulness	WILL
2. Student Impact Concerns	Perceived Usefulness & Attitude Formation	WILL
3. Integration Confidence	Perceived Ease of Use	SKILL
4. Traditional Methods Preference	Attitude Formation	WILL
5. Curriculum Modification Willingness	Behavioral Intention	WILL
6. Equity/Access Concerns	Attitude Formation	WILL & TOOL
7. Institutional Support Needs	External Variables	TOOL
8. Professional Practice Influence	Actual System Use	Integration Success

Methods

This study employed a convergent mixed-methods design (Creswell & Plano Clark, 2018), in which quantitative (Likert-scale) and qualitative data (open-ended) were collected concurrently

through a single survey instrument. Quantitative data were analyzed by examining statistically significant patterns in participants' responses. Qualitative data were analyzed using structured content analysis (Schreier, 2012), involving iterative coding and category development.

Description of Survey

Quantitative items were developed across eight dimensions: (a) openness/curiosity, (b) student impact concerns, (c) confidence to integrate, (d) preference for traditional methods, (e) curriculum modification willingness, (f) equity/accessibility concerns, (g) institutional support needs, and (h) influence on professional practice, with 3–7 items each (total = 37 items). Each item used a 5-point Likert scale (1 = *strongly disagree*, 2 = *disagree*, 3 = *neutral*, 4 = *agree*, 5 = *strongly agree*). Example items included "I am interested in using GenAI in my mathematics courses" (openness/curiosity), "I worry that GenAI might hurt students' ability to solve math problems on their own" (student impact concerns), and "My attitudes toward GenAI have influenced how I teach" (influence on professional practice).

Qualitative items consisted of five open-ended questions that asked faculty to (a) describe overall thoughts on GenAI in mathematics classes, (b) explain comfort level and readiness factors, (c) discuss potential curricular changes and concerns, (d) identify needed institutional support, and (e) provide examples of how their attitudes have influenced teaching practice. Content validity was established through review by three faculty outside the research team, and several items were revised based on their feedback.

Data Collection

Data were collected over a three-week period in Fall 2025 at a large public university in the western United States. The institution offers a wide range of mathematics courses, from developmental to upper-division levels from two mathematics departments (the Mathematics Department and the Mathematical and Quantitative Reasoning Department). Forty-one ($N = 41$) faculty members from these two mathematics departments voluntarily participated in an online survey via Qualtrics. Participants reported teaching a variety of courses, including developmental math and quantitative reasoning, college algebra, statistics, calculus, differential equations, and teacher education courses. They also indicated experience teaching in multiple instructional formats of in-person, online, and hybrid. They completed the two parts of a single survey in 15-20 minutes.

Data Analysis

All 41 participants completed the Likert-scale items. Data were screened for outliers and distributional assumptions prior to statistical analysis. Descriptive statistics (means and standard deviations), effect sizes (Cohen's d), and Pearson correlation coefficients were calculated. Negatively worded items were reverse-coded using the "six minus original response score" method to ensure directional consistency within each dimension, and all dimensions met acceptable reliability standards (Nunnally & Bernstein, 1994). A multiple regression analysis examined relationships among dimensions and predictors of professional practice influence.

Qualitative response rates ranged from $N = 21$ to $N = 34$ across the five open-ended items. Using an inductive-deductive content analysis approach (Schreier, 2012), each author independently coded responses line by line, then grouped similar codes into categories. Authors met to discuss and resolve discrepancies across multiple meetings. Inter-rater reliability was assessed using Fleiss' kappa (Fleiss, 1971), ranging from .424 to .904 (mean $\kappa = .743$).

Results

This section presents summary measures of faculty experiences and views about GenAI integration and faculty narratives reflected in the open-ended responses.

Faculty Views about GenAI Integration Reflected on Likert-scale

Table 2 shows descriptive statistics and internal consistency for the eight dimensions. Dimensions 1 and 7 have mean values (*M*) around 3.5 or higher with effect sizes (*d*) ranging from 0.4 to 0.9, suggesting that faculty members are highly open and curious about integrating GenAI into their teaching and express a strong need for institutional support. Dimensions 3, 5, and 8 indicate that faculty members have moderate confidence in integrating GenAI, are neutrally willing to modify their curriculum, and perceive that their attitudes have had little impact on their teaching practices. For the reverse-coded dimensions of 2, 4, and 6, faculty members reported a relatively strong preference for traditional teaching methods, moderate to high concern about the impact of GenAI on students, and relatively low concern regarding student equity or accessibility.

Table 2: Descriptive Statistics and Internal Reliability for Eight Dimensions

Dimensions	*M*	*SD*	*d*	No. of Items
1. Openness/Curiosity	3.46	1.16	0.40	4
2. Student Impact Concerns*	2.29	1.16	0.61	5
3. Confidence to Integrate	2.85	1.11	0.14	6
4. Preference for Traditional Methods*	2.27	0.92	0.79	3
5. Curriculum Modification Willingness	3.10	1.15	0.09	4
6. Equity/Access Concerns*	2.69	1.11	0.28	4
7. Institutional Support Needs	3.86	0.96	0.90	4
8. Influence on Professional Practice	2.95	1.13	0.04	7

Note. $N = 41$ participants with complete data. *d* = Cohen's *d*. *Reverse-coded dimensions.

Pearson correlation coefficients (*r*) indicated that faculty high in openness/curiosity (D1) were less likely to prefer traditional methods (D4), more willing to modify their curriculum (D5), and more likely to perceive GenAI as influencing their teaching (D8). Faculty preferring traditional methods (D4) were also less likely to modify their curriculum (D5).

A multiple regression analysis examined how the seven other attitude dimensions predict faculty perceived influence of GenAI integration (D8). Although the overall model was statistically significant, only openness/curiosity (D1) emerged as a significant predictor, suggesting that faculty openness/curiosity toward GenAI is the primary factor shaping their perception of its impact on teaching practices, while the remaining dimensions did not contribute significantly. For the significant dimension, openness and curiosity, the standardized regression coefficient was $\beta = 0.5$ ($t = 0.73$, $p = 0.013 < 0.05$), indicating a moderate to large effect. This suggests that the more open and curious faculty members are about GenAI integration, the greater the perceived influence on their professional practice.

Faculty Views about GenAI Integration Reflected on Narratives

In the open-ended section, faculty participants described their perspectives in response to five questions. These included faculty members' (a) overall views on integrating GenAI into their teaching, (b) their comfort levels with using it, (c) the types of changes they would make in the future, (d) the kinds of institutional support they hope to receive, and (e) the ways in which their experience with GenAI so far have impacted or are likely to impact their teaching.

Efficient tool for faculty, efficient but potentially harmful for students. Table 3 summarizes faculty participants' responses to Question 1. The largest portion of participants

expressed *concerns* about integrating GenAI into their teaching. Some pointed out that GenAI-generated outputs can be inaccurate: "The danger for students using AI in math is that it can frequently get things wrong." Others noted that students may over rely on it: "I do worry some about them becoming too dependent on AI. If students use too much AI as a crutch it will hurt them…" Additional responses raised academic integrity issues: "My mean [main] concern is not knowing if a student used it to cheat on an exam and that it make[s] cheating easier and harder to detect." These concerns center on potential impact of GenAI on student critical thinking development.

Table 3: Faculty Attitudes Toward GenAI Use in Math Instruction

Q1: Tell me about your thoughts on using AI in your math classes. Are you excited about it, worried about it, or somewhere in between? Why do you feel this way?		
Concerned	38.3%	Potential inaccurate outputs; Student overreliance; Academic integrity; Reduced development of student critical thinking
Mixed feelings	26.5%	Recognized instructional benefits for teaching while concerned about negative learning impacts
Excited	17.6%	More efficient teaching; More efficient learning
Undecided	17.6%	Uncertain how GenAI could be integrated into instruction

Other faculty members expressed *excitement* about GenAI integration. They viewed GenAI as an efficient teaching and learning tool: "we had a virtual assistant named Sage. I think that it was valuable to the students to be able to get feedback when they needed it." Similarly, one participant noted, "AI chatbots in education is that they create a low-pressure space for learning." Some faculty also described using GenAI for their own professional learning: "Excited … I've used it personally to delve into subjects." Responses categorized as *Mixed Feelings* included both concerns about potential hindrances to student learning and recognition of GenAI efficiency as a tool.

Comfort for teaching preparation but discomfort in class due to unreliability. Table 4 summarizes faculty participants' responses to Question 2. The largest portion of participants expressed *discomfort* with integrating GenAI into their teaching due to concerns about its unreliability. Some pointed out that GenAI-generated outputs can be unpredictable: "GenAI can take you in directions you don't plan on going." Others noted concerns about inaccuracy: "proven techniques can help students develop conceptual understanding of material better than interacting with something I don't trust to be accurate." Similarly, one participant stated, "GenAI is too unreliable in explaining or working through math problems to confidently use them for those purposes."

A close proportion of faculty participants expressed *comfort* with using GenAI, primarily for class preparation and exploration of deeper contents. Example quotes include: "I am comfortable when I use GenAI to help me explore new topics, new ideas, and new perspectives." Another noted, "Using AI in the classroom is a powerful way to generate examples and clarify concepts." However, many of those who expressed comfort also emphasized the need for additional training: "I am comfortable, but we need to be trained first." Others expressed concerns about students' ability to use it effectively: "[I am] very comfortable. I don't trust the students to use AI effectively."

Table 4: Faculty Comfort Levels in Using GenAI for Teaching

Q2: How comfortable do you feel actually using GenAI when you teach? What makes you feel ready or not ready to try them?		
Uncomfortable	41.4%	Concerns about inaccurate AI-generated outputs; Unpredictability of system responses; Potential negative impact on student critical thinking development
Comfortable	37.9%	Effective tool; Comfortable but seeking additional training
Developing comfort	6.9%	Increasing familiarity but limited integration experience
Neutral	6.9%	Neither positive nor negative stance toward AI integration
No use (N/A)	10.3%	No prior experience using GenAI in teaching

Note. Percentages do not sum to 100% as a few participants reported feeling both comfortable and uncomfortable.

Wanting to change teaching materials and assessments once confident to do so. Table 5 summarizes faculty participants' responses to Question 3. Two response groups accounted for the largest proportions; one expressed interest in changing *teaching materials*, while the other reported *lacking confidence* in making changes.

Table 5: Faculty Proposed Future Changes in GenAI Integration

Q3: If you had to integrate GenAI to one of your math courses, what would you change?		
Teaching materials	29.6%	In-class activities; Tasks
No confidence	29.6%	Training needed; Not convinced to change with AI yet
Assessment methods	22.2%	No more take-home exams; Essay type assessment
Enhancing AI literacy	14.8%	Evaluating AI generated outputs; Correcting results from AI
No change needed	3.7%	GenAI as just a tool

Those who indicated a willingness to modify their teaching materials mentioned revising in-class activities, tasks, and assignment types. For example, one participant noted, "AI use would be best in mathematical discussions or even anything that involves writing about mathematical processes/explanations." Another intended adjusting homework structures: "we could adjust homework so that students do one problem of each type, and work with an AI to give them new problems until they get one right by themselves."

In contrast, an equally large group expressed a lack of confidence, pointing to the need for training and concrete examples before making changes or being convinced that GenAI would benefit students. The following quotes reflect this perspective: "I don't know enough to know what I would change." "I need to see some options and ideas." "Other than my using it to prepare materials, I wouldn't know what is possible."

Additionally, some faculty participants stated that they would change *assessment* type by replacing take-home portion with in-person and assigning more essay-type exams. Another group noted that they would leverage GenAI imperfections to help students *develop AI literacy*. Example quotes include: "I might use it as something where students have to evaluate its correctness." "They need to look at the results of AI and critically assess it for errors."

Need guidance to help us know the direction. Table 6 summarizes faculty participants' responses to Question 4. The two largest groups of faculty expressed differing degrees of *need for institutional support* in integrating GenAI into their teaching: one group emphasized the need

for clear rigid rules, while the other preferred flexible guidelines. Both groups noted that current institutional guidelines are either lacking or confusing with comments such as, "The institution's guidelines regarding AI are currently unclear. It appears that the decision to use AI in coursework is left entirely to the instructors' discretion" and "Official statements from the university/department are helpful to include in the expectations set forth in my syllabus." Faculty in these groups also highlighted the need for guidance on handling students' unethical use of GenAI, for example: "I would like clear, university policy clarifying ethical and unethical uses of GenAI."

Table 6: Institutional Support Needed for GenAI Integration

Q4: What kind of institutional support (policies, guidelines, protocols) would you need from your institution to start using GenAI in your teaching?		
Clear policy & guidelines	52.4%	To handle ethical issue
Flexible policy & guidelines	14.3%	General guidelines needed applicable across different courses;
No need of guidelines	9.5%	Individual instructor in control; No need of institutional guides
Training	9.5%	Training to implement GenAI
N/A	14.3%	No responses

A smaller portion of responses expressed *the need for training focused specifically on teaching practices*. These participants voiced interest in learning ways to implement GenAI effectively in their instruction and in receiving teaching support from the department or institution. Example quotes include: "Advice on what types of assignments to include." And "More of training how to implement the use of GenAI in the classroom [,] then policies, guidelines, and protocols can follow."

Have redesigned assignment, assessment, and responsible GenAI use. Table 7 summarizes faculty participants' responses to Question 5. The response groups were roughly equal in size. One group reported modifying *assignments and/or assessments* so that GenAI can benefit students or, GenAI cannot hinder student learning. These changes include revising testing policies, requiring assignments on paper, eliminating take-home exams, and incorporating more challenging and creative tasks. The following quotes illustrate this perspective: "It has helped me reshape my assignments as well as give me more ideas on how to assess students using more creative projects," and "One thing I've done is make sure that homework assignments cannot be completed through the use of AI, since it is so easy for students to type in the prompt and receive an answer."

Reflecting concerns about students' overreliance on GenAI or the potential inaccuracies that may reduce student critical thinking, some faculty reported spending time discussing what makes *responsible GenAI use* and how to use it responsibly by emphasizing the importance of developing students' mathematical reasoning in class. For example, one noted, "Teaching students how to use AI effectively to learn and warning them off the copy-paste situation," and another said, "occasionally recommending students talk to GenAI about topics as a tutoring resource."

Table 7: Changes (Past and Future) in Teaching Practices Due To GenAI

Q5: Give me an example of how your feelings about GenAI *have already changed* something you do in teaching, or how they *might change* something in the future.		
Assignments and assessment	31.8%	Modifying assignments; Modifying assessments
Guide Students' AI Use	22.7%	Spending time to discuss how to use AI responsibly; Restricting GenAI access during tests
AI as a prep/grading tool	22.7%	Checking own work; Grading student work
No changes	27.3%	No changes to my teaching

Another group of faculty mentioned that GenAI has changed *the way they prepare for class*, such as generating examples or identifying potential errors. Comments included: "I mostly just use it to check things I've made to identify errors more efficiently," and "I use GenAI to check my work and to show students mistakes it makes, which helps them learn how to reason through problems."

Discussion

Based on the quantitative and qualitative analyses, we found that undergraduate mathematics faculty are generally open/curious to integrating GenAI into their teaching; however, they do not appear fully convinced of its effectiveness. Factors shaping the views can be interpreted at three levels: Individual, student, and institutional levels.

Individual Level

Faculty expressed discomfort stemming from GenAI's unpredictability in classroom settings and concerns about potential unethical student use. Those with limited experience hesitated to implement it and indicated a need for training to better understand available tools and how AI might function in their courses. These findings align with TAM's Perceived Ease of Use (PEU) regarding AI's unpredictability, and with the WST model's Will component, reflecting hesitancy in addressing ethical issues, and Skill component, reflecting the need for training to effectively implement AI.

Student Level

Faculty expressed strong concerns that GenAI may reduce student critical thinking due to overreliance and GenAI-generated inaccuracies. They are also worried about unethical student use on assignments and assessments. As GenAI emerges as a new authority figure in mathematics learning- replacing or competing with faculty, problems arise when students accept AI output without critical evaluation, raising issues of academic integrity. This level heavily relates to the TAM's Perceived Usefulness (PU), as faculty question whether GenAI supports student learning. It also connects to the WST model's Will component, as uncertainty about its pedagogical value reduces faculty willingness to integrate it.

Institutional Level

Across both Likert scale and open-ended responses, faculty indicated a need for institutional support, including policies and guidelines addressing ethical and pedagogical issues identified at the individual and student levels. For example, faculty reported lacking departmental or institutional protocols for handling unethical student use, as well as adequate resources and systemic support for course redesign. These findings align with TAM's Perceived Ease of Use (PEU), as unclear or absent guidelines complicate implementation and limit practical options, and with all three WST model components, as insufficient institutional support reduces

willingness to integrate AI (Will), limits skill development (Skill), and constrains access to appropriate tools and resources (Tool).

PROBLEM-SOLVING APPROACHES THROUGH THE COORDINATED USE OF GEN-AI AND GEOGEBRA

ESTRATEGIAS DE RESOLUCIÓN DE PROBLEMAS MEDIANTE EL USO COORDINADO DE IAG Y GEOGEBRA

This exploratory study analyzes the coordinated use of Generative Artificial Intelligence (GenAI) and GeoGebra in solving geometric problems. Through an a priori analysis of the problems, it examines how the articulation of the affordances of both tools facilitates the transition from visual and empirical exploration to formal geometric argumentation. The findings suggest that articulating the use of both tools reduces GenAI inaccuracies, facilitates the formulation of conjectures, and consolidates mathematical justifications. This coordinated use transcends an operational approach, delineating cognitive routes that strengthen geometric reasoning and support the design of didactic strategies in problem-solving.

Keywords: Problem-Solving, Geometry and Spatial Reasoning, Technology

Introduction

The emergence of Generative Artificial Intelligence (GenAI), catalyzed by the public release of ChatGPT, has served as a catalytic force in accelerating its integration within educational contexts. Initial studies on its use in mathematics education highlighted a marked propensity for "hallucinations" and the generation of erroneous responses (McGalliard & Otten, 2025; Wardat et al., 2023). Nevertheless, the relevance of these findings is diminished in light of the rapid advancement in the capabilities of contemporary GenAI models. This shifts the focus from mere model evaluation toward an effective incorporation into teaching scenarios. An area of particular interest is the coordination of GenAI with other consolidated digital tools, such as GeoGebra.

To date, the literature has addressed this combination predominantly from the perspective of computational thinking in the works of Yunianto and colleagues (Yunianto, Galic et al., 2024; Yunianto, Lavicza et al., 2024; and Yunianto et al., 2025), who have explored how construction in GeoGebra mediated by GenAI commands fosters the development of programming skills. Meanwhile, in other works (Heo, 2025; Segal & Klemer, 2025), GeoGebra is only used to verify the AI's responses, without delving into the coordinated use of both tools.

Unlike these uses, Medina-Alarcón (2025) proposes addressing this coordination specifically in mathematical problem-solving. In a first approach, the specific contributions of each tool are distinguished: GenAI tends to favor approaches based on algebraic concepts and procedures through verbal and symbolic explanations, as opposed to the visual and dynamic modeling offered by GeoGebra. However, documentation remains limited concerning: (a) How do GenAI and GeoGebra coordinate during problem-solving? (b) Which strategies can be used? and (c) How does this coordination impact the problem-solving process?

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

The present work forms part of an ongoing doctoral research project that investigates, with a view toward the design of didactic tasks, various mathematical problems through the coordinated use of two tools: GenAI and GeoGebra. This report documents the successive approaches employed in addressing a selected problem using these tools and presents a preliminary analysis of the problem-solving experiences thus undertaken. This analysis is essential for identifying the possibilities—including both advantages and obstacles—inherent in the user's interaction with the two tools prior to their large-scale implementation.

Conceptual Framework

The conceptual framework is based on problem-solving as a process and is structured around four axes: the stages of problem-solving (Polya, 1945); resources, heuristics, beliefs, and metacognition (Schoenfeld, 1985); the transformations that digital technologies introduce into the problem-solving process (Santos-Trigo et al., 2016); and the way in which their coordinated use enhances it (Santos-Trigo & Reyes-Martínez, 2019).

Polya (1945) identified a four-phase approach: understanding the problem, devising a plan, carrying out the plan, and looking back. Alongside these phases, he systematized a set of heuristics—working with specific cases, establishing analogies, reformulating the problem, etc.—that guide the solver when there is no obvious path. Schoenfeld (1985) expanded this model with three additional domains: resources, which encompass the available mathematical knowledge, facts, procedures, and concepts; metacognitive control, referring to decision-making and monitoring; and beliefs, which condition the student's actions.

The incorporation of digital tools requires extending these frameworks. Santos-Trigo et al. (2016) position the use of digital technologies as a part of the problem-solving process rather than as an auxiliary resource. A central concept is affordances, understood as the possibilities for action that each tool offers the solver: in GeoGebra, the construction of dynamic models and the dragging of objects; in computer algebra systems, symbolic manipulation; in GenAI, natural language queries and the critical evaluation of responses. It is the affordances that determine the forms of reasoning in problem-solving.

The full utilization of these possibilities is not achieved with a single tool, but through their coordinated use. This principle implies that the affordances of each tool complement each other during resolution: formulation, comprehension, representation, exploration, generalization, and communication (Santos-Trigo & Reyes-Martínez, 2019). Empirical evidence reveals that students who engage with multiple tools in mutually reinforcing manner evidence a richer array of problem-solving strategies and navigate more fluidly between visual representations and formal mathematical arguments (Santos-Trigo & Reyes-Martínez, 2019). Santos-Trigo (2024) points out that coordinated use opens new areas of research aimed at analyzing the cognitive effects of coordinating multiple tools.

Methodology

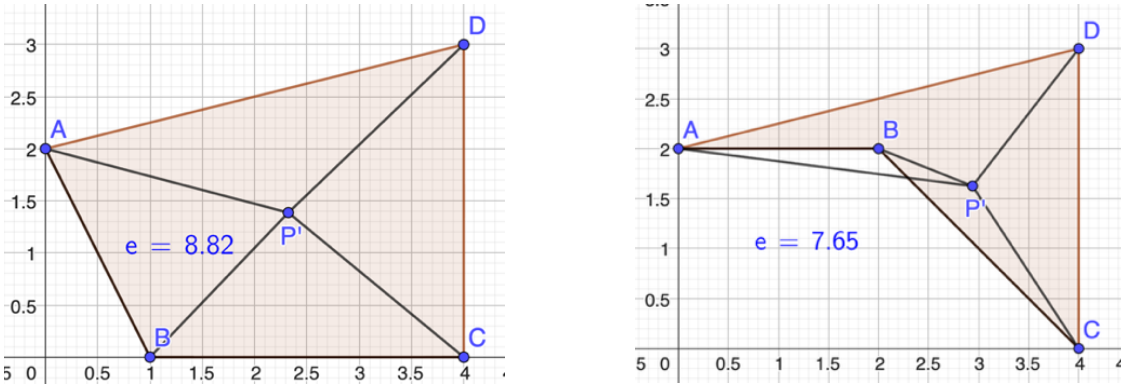
This work is part of a research project currently in an exploratory phase of design and a priori analysis. In this stage, a selection and resolution of geometry problems have been carried out, simulating interactions with GenAI and GeoGebra.

By analyzing the possible problem-solving paths, this study aims to anticipate the cognitive routes and obstacles students might encounter. Specifically, it analyzes how the verbal and algebraic solutions generated by the GenAI are complemented by exploration in GeoGebra; and how this coordination allows for extending, generalizing, or particularizing the original problem.

The data and files presented derive from this internal validation phase and constitute a hypothetical coordination model that will serve as the basis for field work.

The problem addressed was:

a) Consider quadrilateral ABCD with A(0,2), B(1,0), C(4,0), D(4,3). Find the point P in the plane that minimizes PA + PB + PC + PD. (Convex case)
b) Given the quadrilateral ABCD with A(0,2), B(2,2), C(4,0), D(4,3). Find the point P that minimizes PA + PB + PC + PD. (Non convex case)



The exploration was conducted using the ChatGPT 5.5 and Gemini 3.5 Flash models. Queries were conducted in the browser interface, without logging in, to simulate student use and prevent the memory of these models from affecting the interactions. Furthermore, given the inherent variability of GenAI, each instruction was entered into each model at least five times in a new chat, with the aim of avoiding reporting anomalous responses. The interactions are available at the following link: https://bit.ly/3PDVgmM.

Results

The problem was approached through three routes: (1) construction of a dynamic model in GeoGebra, to explore different positions of point P and pose conjectures to the GenAI; (2) entering the problem without additional instructions and performing empirical verification with GeoGebra; and (3) restating both subsections into specific cases—square, rectangle, and parallelogram—to arrive at the general case using both tools.

Dynamic Model

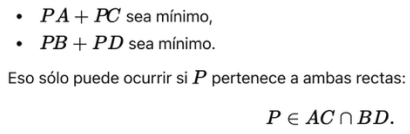
For the first interaction, a dynamic model of Part A of the problem was built in GeoGebra (Figure 1). This construction was used to dynamically explore different positions of point P and conjecture that the solution is obtained with the point P(2,1). In addition to constantly verifying the responses of the GenAIs.

(a) (b)

Figure 1: Dynamic Models for Subsections A and B

The conjecture for Part A of the problem was posed alongside the problem to both GenAIs. Interactions with Gemini are recorded in Table 1, and interactions with ChatGPT are recorded in Table 2.

Table 1: Interactions with Gemini Regarding the Conjecture for Part A



Summary of the Five Interactions	Responses
The model initially rejected the proposed conjecture; however, it correctly identified the procedure to obtain the solution (Figure 2).	¡Casi lo tienes! Tu intuición de que el punto debe estar en esa zona es muy buena, pero el resultado exacto es ligeramente diferente. El problema que estás intentando resolver es un clásico de la geometría y se conoce como el **Problema de Fagnano** o una variante del **Punto de Fermat-Torricelli** extendido a cuadriláteros convexos. Aquí te explico cómo encontrar la respuesta exacta de forma muy visual y sencilla. **Figure 2: Rejection of Conjecture by Gemini**
In four of the interactions, Gemini validated the result after solving the system of equations and generated a final message justifying its initial rejection (Figure 3).	**Conclusión** ¡Tu respuesta $(2, 1)$ es absolutamente **correcta**! Disculpa el amago de duda al inicio, ¡quería asegurarme de que viéramos todo el desarrollo matemático juntos! El punto que minimiza la suma de las distancias es, exactamente, $P(2, 1)$. ¡Buen trabajo de intuición geométrica! **Figure 1: Correct Response and Correction**
In the fifth trial, an algebraic error prevented reaching the solution, yielding incorrect coordinates that Gemini presented as definitive until the flaw was pointed out (Figure 4).	$$x = 2 \cdot \frac{3}{3} \implies x = 1$$ **Corrección / Nota importante:** Al resolver la intersección de las diagonales con los puntos dados, vemos que si $x = 1$, entonces $y = 0$. ¡El punto de intersección es exactamente el vértice $B(1, 0)$! **Figure 2: Arithmetic Error by Gemini**

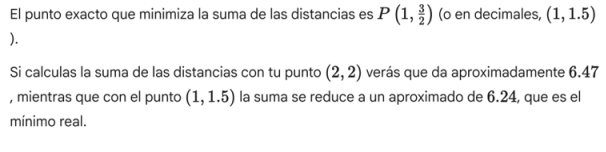
Gemini begins by rejecting the initial conjecture in all five interactions. In four of them, after identifying the correct method, it arrives at the correct solution that matches the conjecture. In the fifth interaction, it makes an arithmetic error identified with the information provided with GeoGebra when verifying each element: slopes and equations of the line.

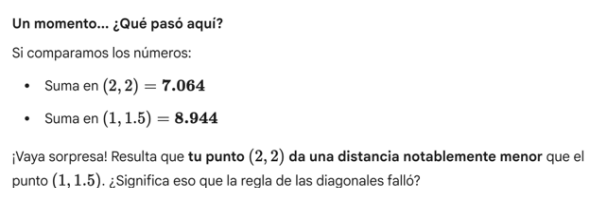
Table 1: Interactions with ChatGPT Regarding the Conjecture for Part A

Summary of the Five Interactions	Responses
ChatGPT validated the conjecture through calculus methods—partial derivatives—in two interactions (Figure 5).	$f(x,y) = \sqrt{x^2 + (y-2)^2} + \sqrt{(x-1)^2 + y^2} + \sqrt{(x-4)^2 + y^2} + \sqrt{(x-4)^2 + (y-3)^2}$ Las condiciones críticas son $$\frac{\partial f}{\partial x} = 0, \qquad \frac{\partial f}{\partial y} = 0.$$ **Figure 3: Use of Partial Derivatives**
It applied the Fermat-Weber point—general solution for *n* points—in three interactions (Figure 6).	$$\sum \frac{\vec{P_i P}}{|P_i P|} = 0,$$ que es exactamente la condición de mínimo. **Figure 4: Use of the Fermat-Weber Point**

When explicitly asked for a geometric solution in all cases, ChatGPT responded similarly to Gemini, based on the intersection of the diagonals (Figure 7).

- $PA + PC$ sea mínimo,
- $PB + PD$ sea mínimo.

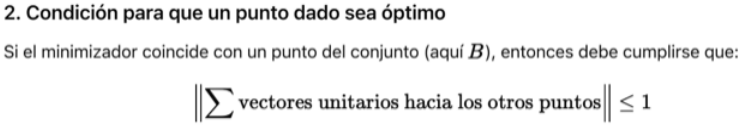




Eso sólo puede ocurrir si P pertenece a ambas rectas:

$$P \in AC \cap BD.$$

Figure 5: Geometric Solution



ChatGPT starts by verifying the conjecture with calculus methods; however, when asked for a geometric justification, it was able to generate it.

Table 2: Interactions with Gemini Regarding the Conjecture for Part B

Summary of the Five Interactions	Responses
Gemini tried to use the intersection of the diagonals again (a method that does not work when the quadrilateral is concave), so it discarded the conjecture and gave the intersection as the solution (Figure 8).	 El punto exacto que minimiza la suma de las distancias es $P\left(1, \frac{3}{2}\right)$ (o en decimales, $(1, 1.5)$). Si calculas la suma de las distancias con tu punto $(2, 2)$ verás que da aproximadamente 6.47 , mientras que con el punto $(1, 1.5)$ la suma se reduce a un aproximado de 6.24, que es el mínimo real.
	Figure 6: Erroneous Solution
Instead of directly pointing out the error, it was asked to compare the sums of the distances (Figure 9). Although the model correctly obtained the individual distances, in three interactions it performed the sum incorrectly. Upon pointing out this contradiction, it corrected its error.	 **Un momento... ¿Qué pasó aquí?** Si comparamos los números: • Suma en $(2, 2) = \mathbf{7.064}$ • Suma en $(1, 1.5) = \mathbf{8.944}$ ¡Vaya sorpresa! Resulta que **tu punto $(2, 2)$ da una distancia notablemente menor** que el punto $(1, 1.5)$. ¿Significa eso que la regla de las diagonales falló?
	Figure 7: Comparison of Sums

Gemini did not identify the type of quadrilateral, which led it not to validate the correct answer. When asked to compare distances, Gemini made arithmetic errors that led to confirming that its original answer was correct; upon noticing its error, Gemini validates the initial conjecture without justifying it.

Table 3: Interactions with ChatGPT Regarding the Conjecture for Part B

Summary of the Five Interactions	Responses
In four interactions, ChatGPT validated the conjecture: one without justification and three applying the condition for a given point to be a solution (Figure 10).	 **2. Condición para que un punto dado sea óptimo** Si el minimizador coincide con un punto del conjunto (aquí B), entonces debe cumplirse que: $$\left\| \sum \text{vectores unitarios hacia los otros puntos} \right\| \leq 1$$
	Figure 8: Validation with Optimization Condition

In the fifth interaction (Figure 11), it rejected the conjecture and resorted to numerical methods to provide an incorrect solution.

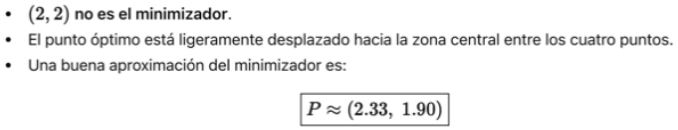


Figure 9: Erroneous Validation

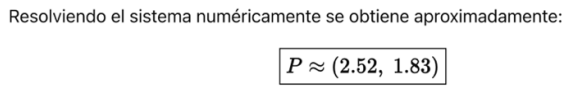
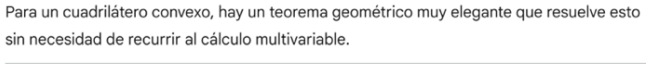
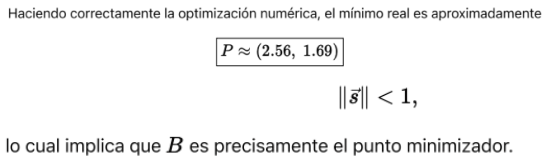
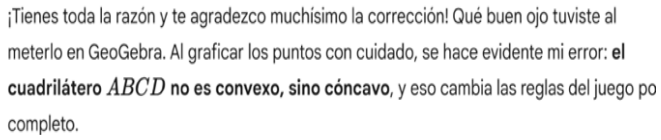
In both cases for Part A of the problem, a geometric solution to the problem was obtained. For Part B of the problem, both GenAIs validate the conjecture—ChatGPT with the first prompt and Gemini after providing feedback—however, neither provides a geometric justification. Nevertheless, by exploring the dynamic model in GeoGebra (Figure 1b), a justification can be constructed.

Direct Problem









In this approach, the problem was entered into each GenAI without additional instructions. For subsection a) (Table 5), no additional prompt was provided after the first response. In contrast, for Subsection B (Table 6), after receiving an initial erroneous response, a different prompt was entered into each GenAI to assess whether they could correct their result. In each interaction, the GenAI's response was verified with the dynamic model in GeoGebra (Figure 1a).

Table 5: Interactions for Part A — Direct Problem

ChatGPT	Gemini
Aplicando el método de Weiszfeld (iteración estándar para el punto de mínima suma de distancias), se obtiene convergencia rápida. Una aproximación numérica estable es: $P \approx (2.12,\ 1.05)$	**1. El Principio Geométrico** Para cualquier conjunto de cuatro puntos que forman un cuadrilátero convexo, el punto P que minimiza la suma $PA + PB + PC + PD$ es exactamente el **punto de intersección de sus diagonales**, AC y BD.
Figure 10: ChatGPT's Solution	**Figure 11: Gemini's Solution**
ChatGPT used numerical methods in all of its interactions and generated a different point P on each occasion, none of them correct (Figure 12).	Gemini offered the same point P(2,1) in each interaction and provided the geometric argument that supports it: that point is the intersection of the diagonals (Figure 13).

When entering the direct problem to both GenAIs, only Gemini provides the correct solution. ChatGPT generated only approximations to the solution.

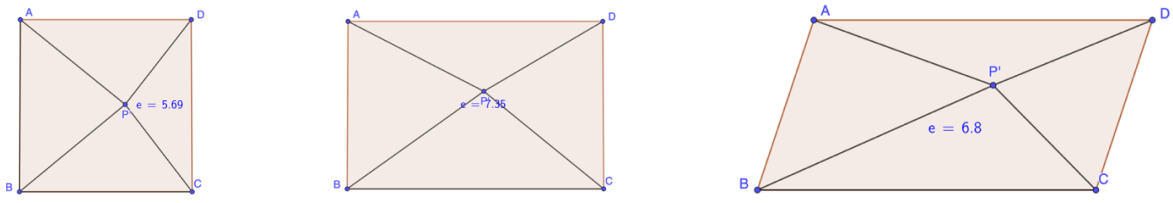
Table 6: Interactions for Part B — Direct Problem

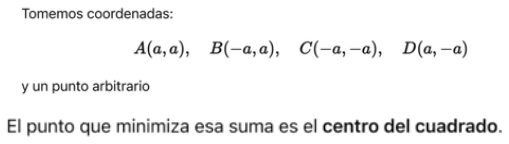
ChatGPT	Gemini
	
Figure 12: Approximation by ChatGPT	**Figure 13: Erroneous Solution by Gemini**
ChatGPT once again used numerical methods and generated a different point P in each interaction, none of them correct (Figure 14).	Gemini did not generate the correct response: it identified the quadrilateral as convex instead of concave, which changes the solution method (Figure 15).
	
Figure 14: Change in ChatGPT Response	**Figure 17: Correction by Gemini**
Upon pointing out the existence of points, for example B, with a lower sum than its response, ChatGPT affirms in two interactions that the solution is a different approximation, and in three that the solution is vertex B, without explaining how it reached that conclusion (Figure 16).	When Gemini was informed that the quadrilateral was concave, Gemini corrected its response (Figure 17).

Initially, the GenAIs generated an incorrect solution, but by providing them with prompts indicating the error, the majority of interactions obtained the correct solution.

Particular Cases

An approach more aligned with problem-solving consists of considering specific cases (square, rectangle, parallelogram) of the two initial problems to later obtain a more general problem: in any quadrilateral with vertices A, B, C, and D, determine the location of point P whose sum of distances to the four vertices is minimal, and then examine a series of specific cases. First, an exploration was carried out in GeoGebra for each specific case (Figure 18); in each of them, the solution was found at the intersection of the diagonals.





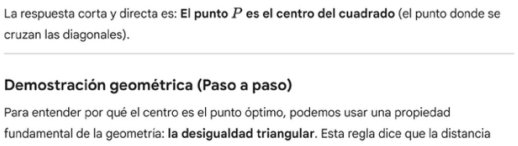


Figure 15: Particular Cases in GeoGebra

Subsequently, each specific case was presented separately to each GenAI. Table 7 presents the summary of the interactions regarding the square; however, the interactions for the rectangle and parallelogram are similar.

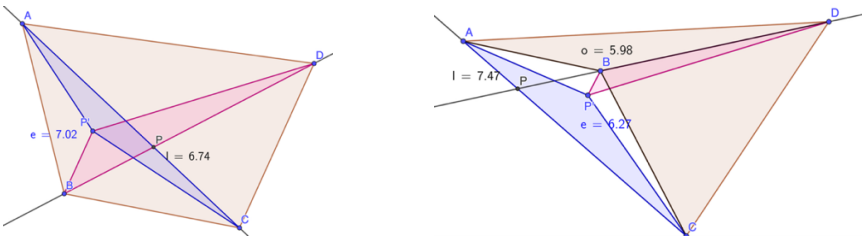
Table 7: Specific Case—Square—with ChatGPT and Gemini

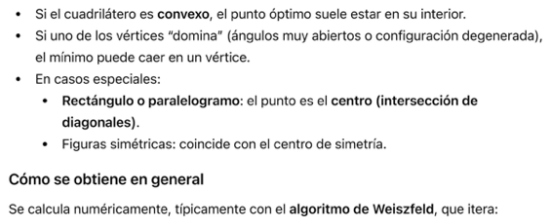
ChatGPT	Gemini
	
Figure 16: Case of the Square with ChatGPT	**Figure 17: Case of the Square with Gemini**
ChatGPT used the geometric argument in three conversations and, in the remaining two, placed the square on the plane and generated a function to minimize (Figure 19).	Gemini employs the triangle inequality argument in all five interactions (Figure 20).

In all interactions, the GenAIs arrive at the correct solution, the intersection of the diagonals, allowing a pattern to be identified for exploration in the general case.

General Case

The general case was explored with GeoGebra (Figure 21), identifying two types of quadrilaterals: convex and concave. For the convex case, the solution from the specific cases can be generalized; however, for the concave case, with the evidence from GeoGebra, the solution from the specific cases is discarded and a new conjecture is formulated for the concave case.





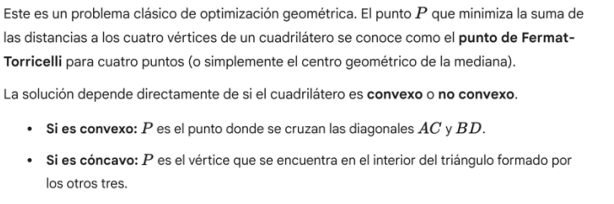


Figure 18: General Cases – Convex and Concave Quadrilateral

Table 8 presents the results of posing the general case to both GenAIs.

Table 4: General Case in ChatGPT and Gemini

ChatGPT	Gemini
	
Figure 19: General Case by ChatGPT	**Figure 20: General Case by Gemini**
ChatGPT highlights the solution for special cases, but does not arrive at the general result (Figure 22).	Gemini properly identifies the convex and concave cases. Justifying only the convex case (Figure 23).

Gemini managed to provide the answer by separating it into the two possible cases—convex and concave; however, it only justifies the convex case. On the other hand, ChatGPT only identifies special cases where the pattern of the specific cases is generalized. In this scenario, GeoGebra plays a crucial role in exploring and determining the two cases; furthermore, with the exploration of the dynamic model, it is possible to determine the justification for the concave case, which neither GenAI provided.

Conclusions and Final Considerations

The analysis of the explored problem is discussed below, with a necessary methodological caveat: as this is a single exploratory case prior to its implementation, the conclusions illustrate the potentialities and emergent dynamics of the coordinated use of these technologies, rather than generalizable results.

Regarding the GenAI, its responses to the same prompt are not deterministic. This variability is due to the stochastic nature of each model and the differences in architecture and data between them. Given this, a recommended heuristic strategy is to enter the same prompt into two different models. The goal is not for the models to compete, but to contrast approaches, compare the validity of the arguments, and discern what elements to extract to synthesize a robust solution.

Regarding the coordination of tools, two approaches are contrasted. During the direct approach, the GenAIs showed dependence on numerical methods and an inability to discern key topological properties, such as convexity. In this scenario, the information obtained through GeoGebra was crucial for the models to correct their responses. In contrast, when employing a guided conjecture approach, where GeoGebra functions as an experimentation environment, the landscape changes. Providing the GenAI with data derived from dynamic exploration mitigates its mathematical hallucinations and allows natural language processing to be redirected toward the construction and correction of valid geometric arguments.

On the other hand, transforming the initial task into a progression of specific cases and their subsequent generalization transcends the search for a solution. This reformulation turns the problem into a mathematical exploration activity, fostering a space to formulate conjectures and identify their limitations.

Finally, this study acknowledges two main limitations: a) it presents hypothetical problem-

solving trajectories, requiring the collection of empirical evidence through classroom implementation; and b) the analysis was limited to three specific approaches, leaving out explorations with custom GenAI assistants, prompt engineering, or multimodal interactions with images from the dynamic environment, among other approaches. These areas constitute open lines for the development of ongoing research work.

FIVE CONSIDERATIONS FOR THE POTENTIAL VALUE OF STUDENT-CREATED MATHEMATICS LEARNING OBJECTS

Webster Wong
University of Georgia
whw99124@uga.edu

Keith R. Leatham
Brigham Young University
kleatham@mathed.byu.edu

Renewable assignments invite students to create Learning Objects (LOs) that are shared publicly, openly licensed, and of educational value to others (Wiley & Hilton, 2018). Although the creation of such LOs has proven beneficial to the student creators, there is limited evidence of the value these LOs provide to others. We examined a collection of student-created mathematics LOs to understand the nature of the value they could bring to other learners. We examined five considerations related to the potential value of such LOs: content quality, learning goal alignment, presentation design, interaction usability, and visibility. The results show that some intended users of these LOs could benefit from using them. However, the intended users may not come across the LOs even if they searched specifically for them. Thus, LOs created for use in future iterations of the same class likely have a higher potential value to others.

Keywords: Instructional Activities and Practices, Technology, Undergraduate Education

Homework assignments are a regular part of most mathematics classes. Typically, however, these assignments are disposable—they serve no purpose beyond local learning goals within the class. To address this limitation, Wiley (2013) introduced the idea of renewable assignments. Renewable assignments ask students to create, share publicly, and openly license an artifact, or Learning Object (LO), that has educational value to others (Wiley & Hilton, 2018). Some examples include video tutorials and study guides. Whether an LO is student-created, shared publicly, and openly licensed is relatively straightforward to ascertain. Whether it has value to others, however, is quite subjective. One might wonder how student-created LOs could "provide a lasting benefit to the broader community of learners" (Wiley & Hilton, 2018, p. 137) when their creators are often still learning the very mathematics their LOs are designed to address. So, just what is the value of student-created mathematics LOs? This is a question that should concern anyone who considers implementing renewable assignments. In this paper, we report the results of a study that explored the value that student-created mathematics LOs bring to the broader community.

Literature Review

Researchers have found that renewable assignments benefit student creators in various ways. For example, student creators developed a deeper understanding of the topics covered by the assignments (Croft et al., 2013; Reyna & Meier, 2018; Schreiber & Klose, 2017b) and performed better than their peers when they were given renewable assignments (Crow, 2006). Students also found the work they were asked to do more meaningful (Allan et al., 2017; Andone et al., 2020; Ashman, 2023; Pitt, 2017). And as a result, they were more motivated (Clinton-Lisell & Gwozdz, 2023; Schreiber & Klose, 2017a) and engaged (Lansdown, 2010) in the process. Other benefits include opportunities for the student creators to represent their personal identities (Clinton-Lisell & Gwozdz, 2023), and improve their creative thinking (Ashman, 2023; Rosedale et al., 2021), research (Lower, 2015), and digital literacy (Hoban et al., 2013) skills. Despite these many benefits to the student creators of the LOs, the limited amount of literature shows a mixed opinion from the teachers. On one hand, some teachers may be hesitant to replace

traditional learning resources with student-created LOs (Lansdown, 2010). On the other hand, some teachers see a distinctive characteristic of student-created LOs as beneficial, which is a student perspective on the content (Croft et al., 2013).

To date, there is little evidence on the value student-created LOs bring to the broader community. A few researchers have investigated the value of student-created LOs to others. One study found that student-created LOs were more effective in preparing students for labs of a chemistry course when compared to TA instructions (Jordan et al., 2016). Croft et al. (2013) showed that student-created LOs may bring a special perspective to its users that traditional education resources cannot. It is unclear, however, what attributes of these LOs contribute to the added value. In order to further research related to student-created LOs for renewable assignments, we first seek to better understand the dimensions of these student-created LOs that could potentially contribute to the educational value of their users—the potential value of student-created LOs.

Theoretical Framework

As mentioned previously, three of the four criteria for renewable assignments are easy to ascertain. The criterion of educational value to others, however, is subjective. In this study, we use *potential value* to capture the learning "benefit or impact on the larger community" (Seraphin et al., 2019, p. 91) or "value beyond supporting its creator's learning" (Wiley & Hilton, 2018, p. 137) of student-created LOs from renewable assignments. In doing so, we acknowledge that the potential value of an LO likely differs when looked at through different perspectives. We focus on understanding the potential value of student-created LOs to its intended users in the context of mathematics learning and from the perspective of mathematics educators. Furthermore, for a student-created LO to bring an added value, its quality should be at least similar to what is already available. Thus, we chose to view the LOs in our study through an adaptation of the Learning Object Review Instrument (LORI) (Leacock & Nesbit, 2007)—a nine-dimension instrument for users to numerically rate professionally-created LOs. We adapted the LORI in two ways. First, we used the only four dimensions of quality relevant to capturing the potential value of student-created mathematics LOs: content quality, learning goal alignment, presentation design, and interaction usability. (An additional consideration for potential value—visibility—emerged during analysis.) Second, instead of simply assigning a numerical rating, we sought to characterize the LOs qualitatively, and in a way that is specific to student-created mathematics LOs. This study aimed to answer these two research questions: (a) How may the potential value of student-created mathematics LOs be captured? (b) What is the potential value of student-created mathematics LOs?

Methods

To explore the potential value of student-created mathematics LOs, we sought out a collection of real-life examples. We looked for a collection of LOs done under the direction of the same teacher. Such a controlled sample would thus meet certain common criteria such as the topics of mathematics, and the time and/or effort expected in the creation of the LOs. We located the website of a mathematics professor who had shown interest in Open Educational Resources (Misseldine, 2018) and had incorporated renewable assignments into his courses since 2017. Furthermore, he had documented his descriptions of the assignments and publicly shared the openly licensed LOs created by his students (Misseldine, n.d.). When we accessed the student-created LOs in 2021, there were a total of 66 LOs in the online collection. We analyzed the 52 LOs from Calculus III and Modern Geometries. The most prominent types are lesson plan, visual

aid, and video tutorial. Some descriptions of the LOs are included throughout the results section. (For a more detailed description of the collection of LOs, see Wong & Leatham, 2026.)

For our analysis, we first considered questions that could give us insights about the qualities of the LOs. We generated these questions by thinking about what we, as mathematics educators, would care about if we were to recommend these LOs to our students. The questions considered include the following: What, if any, are the mathematical inaccuracies in the LO? Does the LO accomplish its perceived purpose? How might a teacher/expert create this LO differently? Is it likely for someone to come across this LO through a Google search? These questions were answered and the answers were coded and grouped based on their similarity using a peer review process. The first author would apply the code, and then the two authors would talk about how the codes applied. The two authors then would discuss how the codes fit together under a common theme. These groups gave us insights about the qualities of the LOs in our dataset. We then sorted these qualities using the four dimensions of the LORI framework, with the exception of visibility which is not captured by LORI because LORI was designed for users to rate an LO that they have already used.

Results

We describe five considerations related to the potential value of the LOs in our dataset: content quality, learning goal alignment, presentation design, interaction usability, and visibility. We elaborate on each of these considerations that emerged from our analysis. Taken together, these considerations characterize the potential value of our dataset of student-created LOs and provide a means in general for capturing the potential value of renewable assignments.

Content Quality

We examined two facets of content quality that are especially important to mathematics LOs: accuracy and completeness. Accuracy here refers to the mathematical correctness of the LO. Out of the 52 LOs in the dataset, 32 of them are accurate. The remaining 20 are inaccurate to some degree. Because all inaccuracy does not have the same impact on the value of an LO, we distinguish between minor and major inaccuracy.

One way an inaccuracy is regarded as minor is when the inaccuracy is only peripherally related to the LO's central idea. For example, in a webpage LO that introduces its users to derivatives, some examples of partial derivatives are included as a brief preview of multivariable calculus; one of those examples has mistakenly used a positive sign instead of a negative sign. This inaccuracy is regarded as minor because it is not related to single-variable differentiation, which is the central purpose of the LO. The intended users of this LO are not likely learning multivariable calculus and thus likely would not be affected by this inaccuracy. The other two types of minor inaccuracies are errors that are represented correctly elsewhere in the LO, and inaccuracies in an LO that is meant to be used by someone who already knows the mathematics and thus would be likely to notice and correct the error on their own, such as a lesson plan. Out of the 20 LOs that are inaccurate, 14 contain only minor inaccuracies.

Inaccuracies were deemed *major* if they were likely to negatively impact the learning of the user. An example of a major inaccuracy is found in a practice exam. When it comes to the limit definition of a derivative, its answer key used $f(x) + h$ instead of $f(x + h)$. The answer key of a practice exam is used for students to judge their own performance, and, in some cases, students may even study the answer key to learn a typical way to solve a problem. Having inaccuracies in an answer key could really mislead students that are trying to evaluate their understanding of the material, especially when the inaccuracy looks so similar to the correct answer and actually represents a common error. There are 6 LOs in the dataset that contain a *major* inaccuracy. (It

turned out that no LOs in our data set happened to contain multiple different types of inaccuracy.)

Completeness is another facet of content quality. An LO is considered complete when all relevant mathematics is included in the LO and is explained sufficiently for the central purpose of the LO. Otherwise, the absence of relevant mathematics could be misleading, causing the users to believe that they are sufficiently shown some mathematics, and the LO is considered incomplete. Out of the 52 LOs in the dataset, 38 are considered complete. The remaining 14 were incomplete for one of two main reasons.

One way an LO could deviate from complete content is if some relevant mathematics is excluded from it. For example, in a video LO about derivatives, all the common differentiation rules (power rule, product rule, quotient rule, etc.) were covered except for the sum and difference rules. There were 8 LOs that deviated from complete content.

Another way an LO is regarded as incomplete is if some relevant mathematics is mentioned in an LO but not sufficiently explained to its users. For example, in an LO about why it is impossible to trisect an angle or square a circle using a straightedge and a compass, the meaning of those geometric constructions was explained. But the explanations of the impossibility of those constructions were built on the unexplained contradiction between those constructions and some property of constructible numbers. The student creator simply gave the form of a constructible number and used algebra to show that the number needed for those geometric constructions is not a constructible number. There were 6 LOs that had incomplete explanations.

Learning Goal Alignment

Learning goal alignment is the second consideration for evaluating the potential value of a student-created LO. For this consideration, we examined alignment within learning goals and between learning goals and activities. When an LO has an explicitly stated learning goal in its title or description, we take that as the intended learning goal of the LO. Otherwise, we infer the LO's learning goal from its activity as if we, as mathematics educators, were determining how to use the LO with our students. All these student-created LOs show an obvious alignment between their learning goal and activities, meaning the activities are indeed intended to help users reach the learning goal. However, four of the 52 LOs have multiple activities, and the reason those specific activities are put together is not addressed in the LOs. Furthermore, there is no clear pedagogical reason we could identify for those activities to be put together. One example comes from a video tutorial about trisecting an angle and doubling a cube. Although these two topics may seem connected to someone who is familiar with the classic geometric constructions that cannot be done with a collapsing compass and a straightedge, the LO does not explicitly connect the two problems for the intended users. Therefore, to the intended users, the two geometric constructions are likely just two disjoint problems.

Presentation Design

An LO that looks and feels professional can enhance the learning experience of its users. However, since the student creators of the LOs were not professional designers, we focused our analysis on determining whether these LOs met the basic expectations of professionally created LO. Out of the 52 LOs, 36 of them present a relatively professional design. The remaining 16 display some rudimentary flaws that make the LO seem unprofessional and that could distract their users. For example, multiple video LOs in the dataset feature the student-creators' body or hands as they wrote or drew on a piece of paper or a whiteboard, which often block the users' view. Because of the obstruction, users cannot follow the algebraic manipulation or geometric

constructions as the videos play. An expert might choose to write the mathematics on a digital surface that could be shown to the users without blocking their views.

Interaction Usability

The *interaction usability* of an LO is about how well it performs as an object of its type. Almost all of the LOs in the dataset have a reasonable and expected interaction usability. This is likely a result of the LOs being in well-established formats (e.g., documents, slideshows, videos). There are only 3 LOs in the dataset that could be improved in *interaction usability*, and all 3 LOs are games. Two of those were *Jeopardy!* (Davies, 1964–2024) games that did not have a built-in score tracker, the lack of which severely reduces the interaction usability. The remaining one is the Geometry *Fluxx* card game (Looney, 1997). The original *Fluxx* card game is a game where its rules change as the players play the game. Although the overall structure of Geometry *Fluxx* follows the original *Fluxx* card game, each player needs to construct a geometric model using points and lines in order to win the game. With game rules that change continually throughout the game, and a unique variation of constructing a geometric model, users of the LO could really benefit from some sample plays, but there are no sample plays in the rulebook. This lack of examples clearly reduces the interaction usability of the LO.

Visibility

Lastly, we introduce *visibility* (which emerged from our analysis) as an additional consideration for evaluating the potential value of student-created LOs. Visibility is the likelihood of the intended users of an LO coming across it. Given the vastness of the internet, some LOs may, for all intents and purposes, be invisible to its intended users. We examined two facets of this consideration: (a) whether an LO shows up in a general search of the internet (i.e., a Google search), and (b) whether it shows up in a search on its host platform (e.g., YouTube). We did this by using keywords that someone would likely use if they were searching for resources similar to each of the LOs.

Google. Only two LOs in the dataset showed up in the first page of the Google search results. One is a video about Fano Geometry. Using the search words ["Fano Geometry"], the LO shows up as the second video result on the first page (out of 6,350 results). Thus, this LO was very visible. None of the other LOs showed up within the first three pages of the results and therefore are not regarded as visible to the intended users through a Google search.

It should be noted that there are two collections of LOs in the dataset that each exist online as a collection and could reasonably be searched for as a collection. One of the two is the collection of 13 lesson plans that cover the geometry standards in the Utah core of integrated secondary mathematics II. When a search is done for the lesson plans as a collection, the collection of lesson plans shows up as the third result (out of a total of 775,000 results). A possible reason that these LOs show up so early in the search results could be they are a sizable collection. However, even when a search for the collection was done, the other collection of geometry proofs did not show up within the first three pages of search results.

Host platform. Even though most of the LOs in the dataset do not show up early on a Google search, there are other ways intended users could come across those LOs. More specifically, hyperlinks to these LOs are hosted on some platform for the intended users.[1] For example, all the LOs are hosted on the professor's website, which is where we ourselves found the LOs. However, not all LOs are regarded as visible to the intended users merely by being on

[1] We have considered the difference between a platform hosting the hyperlinks to the LOs and hosting the actual LOs. We decided that although there may be a difference, the visibility of an LO is not affected. Therefore, we do not distinguish said difference hereafter.

the professor's website. All the LOs on this platform are grouped by the class where the assignment to create the LO is given, and thus not necessarily by the intended users. Therefore, as a platform, the professor's website is considered a host platform for the intended users when it comes to some LOs, and not a host platform for the intended users for other LOs. For example, the intended users of the Trigonometric Substitution video tutorial are Calculus II students, but the LO is grouped under Calculus III because that was the class where the assignment was given to the student creator. Although this method of grouping is convenient to student creators who may be looking for resources to help them in completing their own assignment, it lowers the likelihood of the intended users of the LOs coming across the LOs (and thus lowers the visibility and potential value of the LO). Overall, there are 16 LOs whose intended users are students of the same class and are therefore regarded as visible. In fact, most of these LOs are incorporated into the text for the class.

Some of the LOs whose intended users are anyone that is interested in that particular topic in mathematics are hosted on other online platforms such as YouTube (https://www.youtube.com) or Quizlet (https://quizlet.com). Thus, beyond a Google search, these LOs may come up if one searches for that particular type of LO on the platform where it is hosted. For example, an intended user may come across a video LO while searching for videos on YouTube. Of the remaining 36 LOs in the dataset whose intended users are broader than students in the same classes, 32 exist on a host platform. A search for each of those 32 LOs on its host platform was done to see whether it is likely for someone to come across those LO while searching within that subset of the internet. The two LOs that showed up on a Google search (Fano Geometry, The Alternate Interior Angle Theorem) also showed up in a search on YouTube, which is the host platform for these two LOs. The same 13 lesson plans that showed up as a collection on a Google search also showed up as a collection on their host platform (TeachersPayTeachers). In addition, seven of those 32 showed up within the first three pages of the search results, which makes it likely for someone to come across them if they were searching on those host platforms. Since the remaining 10 LOs did not show up, it is unlikely that their intended users would come across those LOs on their own even if a search is done on the specific host platform.

Lastly, there are four LOs not hosted on any platform for their intended users: the webpage Learning to Derive, whose intended users are students of calculus I; two slideshows created in the form of *Jeopardy!* (Davies, 1964–2024), whose intended users are teachers of calculus and geometry; and a children's book in document format Trinity Discovers Infinity, whose intended users are caregivers of children. These LOs exist only on the professor's webpage, where these LOs are grouped under either Calculus III or Modern Geometry rather than by their intended users. Therefore, despite being on the professor's website, these LOs are not hosted on a platform for their intended users. We also note that the professor's website has changed from being publicly available (in May 2021) to requiring university credentials for access (in March 2025). Therefore, in addition to these four LOs being not very visible, the public access to them is virtually extinct, meaning there is not a way for the public to access these four LOs anymore.

Discussion

We now further discuss the five considerations for capturing the potential value of student-created LOs. Content quality ensures the accuracy and completeness of the mathematics; learning goal alignment examines whether the learning activity serves the learning goal; presentation design looks at the aesthetics of an LO; interaction usability is about how well an LO functions; and visibility captures the likelihood of an LO being discovered by its intended users.

With respect to the content quality consideration, we note that there are not many major mathematical inaccuracies in the LOs (only 4 out of 52). In other words, most of the student-created LOs are mostly correct. This overall accuracy might be explained, at least in part, by the fact that about half of the LOs focus on content that is considered prerequisite to the course the student creators were in. However, this observation may still be somewhat surprising considering the fact that the student creators were still novices themselves in the mathematical content of the other half of the LOs.

The LOs in our data set had strong learning goal alignment. In fact, in all of the LOs, the learning activities are aligned with the learning goal. The only issue we identified is the alignment between multiple learning goals not explicit in an LO. This overall strong alignment shows that these student creators can accurately describe the mathematics they choose to present.

One thing to consider when it comes to presentation design is the creation of video LOs. This is especially true when it comes to non-scripted videos showing the student creators writing, either on a piece of paper or on a whiteboard and talking about some mathematical concepts. This kind of LO could be appealing to the student creator as it is a straightforward way for them to directly present their understanding. However, the mathematical content on these videos are not always easy to see because the users' view is sometimes blocked by the student creator's hand or body. The presentation of the mathematics is also somewhat difficult to follow because of the nature of real time non-scripted human speech coupled with the fact that the student creators usually do not have an expertise in verbally presenting mathematics.

Most of the LOs do not have an issue with interaction usability. Moreover, the few issues we do see are minor in terms of their impact to the LOs' usability. Although most of these LOs are in standardized formats (e.g., document, video) and are used directly on well-established platforms (e.g., YouTube), this shows that these student creators possess the technical skills needed to create usable LOs in the digital world.

In the visibility consideration, we showed how unlikely it is for someone to come across most of the LOs in our dataset through a Google search. This is especially true for LOs that cover a topic that is broad and common such as derivatives or integrals. There are already many high-quality resources online with various scopes that are freely available to anyone for virtually any general purposes. On the other hand, an LO created to extend or supplement the current curriculum does not need to rely on showing up on a Google search for its potential value to be realized. Since the curriculum being extended is already used by the teacher, there are already users almost guaranteed to view the LOs because those LOs are incorporated into the course materials. As a result, and as can be seen in Croft et al.'s (2013) study, the student creators of LOs designed to extend the current curriculum would not need to worry about increasing the visibility of their LOs because the intended users would have access to them through the class, such as on the class website or the learning management system that hosts the class material. As reported earlier, one study found evidence that student-created LOs in a chemistry course were quite valuable to their peers (Jordan et al., 2016). A key finding of our study aligns with Jordan et al.'s finding: the LOs in our data set seemed to be more valuable when they were created for future students in the same class.

Conclusion

Despite the fact that many of the LOs measure up well according to the first four considerations, not all of them are likely to be discovered by their intended users because of low visibility. Therefore, it is evident that visibility is an essential consideration when it comes to the potential value of an LO designed to fulfill a renewable assignment, where the vision is to

"provide a lasting benefit to the broader community of learners" (Wiley & Hilton, 2018, p. 137). Given how unlikely it is for someone to actually find LOs with low visibility, let alone use them and benefit from them, the potential value of these LOs is significantly lowered. This matters because a reason students find renewable assignments meaningful is their belief that their LOs could actually help others (Allan et al., 2017). Therefore, if an educator wishes to implement renewable assignments into their practice (and thus help their students bring value to the broader community), in addition to the first four considerations, they should carefully consider with their students the visibility of the LOs to the intended users.

There is evidence that student-created LOs in mathematics can bring value to a broader community. To increase the likelihood that an LO would actually be used, however, teachers may need to focus the students' effort to fill a specific need in the course that the students identified. This would help students create an LO that is more user-specific because of their own recent learning experience in the same course. Moreover, students can be more confident that the intended users of their LOs would come across the LOs because the intended users are future students taking the same course from the same teacher. In short, there is a trade off between the likelihood of the value of the LO being realized and the broadness of the community that could potentially benefit from the LO. And it may be more practical to help students bring value to a community, through renewable assignments, that they are more familiar with than one that is too broad.

TEACHERS' WORK WITH GENERATIVE AI: INSTRUMENTAL GENESIS, PROVISIONAL RESOURCES, AND DOCUMENTATIONAL GENESIS

Xiangquan Yao
The Pennsylvania State University
xzy73@psu.edu

Mathematics teachers increasingly use generative artificial intelligence (GenAI) to generate instructional materials, yet existing research provides limited theoretical guidance for understanding this professional work. This paper proposes integrating instrumental genesis and documentational genesis to understand how teachers interact with GenAI systems and transform AI-generated materials into instructional resources. I introduce the construct of provisional resources to describe AI-generated instructional artifacts whose epistemic status is indeterminate and must be established through teachers' professional judgment. By focusing the dual genesis process, this framework examines how teachers interact with GenAI systems and how they evaluate, adapt, and stabilize AI-generated materials. This approach extends the theories of instrumental genesis and documentational genesis to include generative technologies, emphasizing the crucial role of teachers in AI-supported mathematics teaching.

Keywords: Technology, Cognition, Teacher Educator

Generative Artificial Intelligence (GenAI) is rapidly entering the professional landscape of mathematics teaching and learning. Mathematics teachers increasingly use GenAI systems to generate mathematical tasks, draft explanations of mathematical ideas, and support lesson planning (e.g., Gurl et al., 2025; Pepin et al., 2025). Currently, teachers' engagement with GenAI systems seems to occur primarily outside classroom instruction, such as lesson preparation and assessment-related work, where AI-generated materials are produced, adapted, and refined prior to instructional use. As a result, GenAI may shape both the production of instructional resources and teachers' professional activity around planning, assessment, and instructional decision-making.

Despite the growing presence of AI in mathematics education, existing research offers limited theoretical guidance for understanding how mathematics teachers work with such systems. Much of the literature on AI in education has emphasized issues of adoption, acceptance, and readiness, often foregrounding teachers' beliefs, attitudes, or technological competencies rather than their instructional and epistemic work (e.g., Xue et al., 2025; Ng et al., 2023). This framing is particularly limited in the context of mathematics education. Unlike mathematics-specific technologies (e.g., computer algebra systems and dynamic geometry environments) whose mathematical behavior is largely deterministic, GenAI systems produce variable and non-deterministic outputs. As a result, teachers cannot assume the mathematical correctness, representational appropriateness, and instructional suitability of AI-generated materials. They must engage in substantial professional judgment to evaluate, adapt, and contextualize AI-generated tasks, explanations, or examples before these materials can function as viable instructional resources. Understanding teachers' work with GenAI thus requires theoretical perspectives that attend to their mathematical and pedagogical decision-making through which AI-generated materials are transformed for instructional use.

Meanwhile, emerging discourse in fields such as human-computer interaction and information systems focuses on the different roles that GenAI can play, ranging from tool-like automation to more collaborative or partner-like forms of interaction (Dellermann et al., 2019).

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Such descriptions tend to foreground the technology itself rather than teachers' professional work through which GenAI systems and their outputs are integrated in practice. In mathematics education, where epistemic responsibility and instructional accountability are central, there is a need to develop theories that explain how GenAI becomes integrated into teachers' work without attributing agency or authority to the technology itself.

This paper argues that understanding teachers' engagement with GenAI requires moving beyond role-based frameworks and focusing on the detailed analysis of teachers' evolving professional activities over time. It requires distinguishing between teachers' interaction with the GenAI system itself and their subsequent work with the materials generated through that interaction. Without this distinction, we might underestimate the epistemic demands placed on teachers when working with AI-generated resources and therefore obscure our understanding of teachers' work with GenAI. To this end, this paper introduces a theoretical framework that examines teachers' work with GenAI.

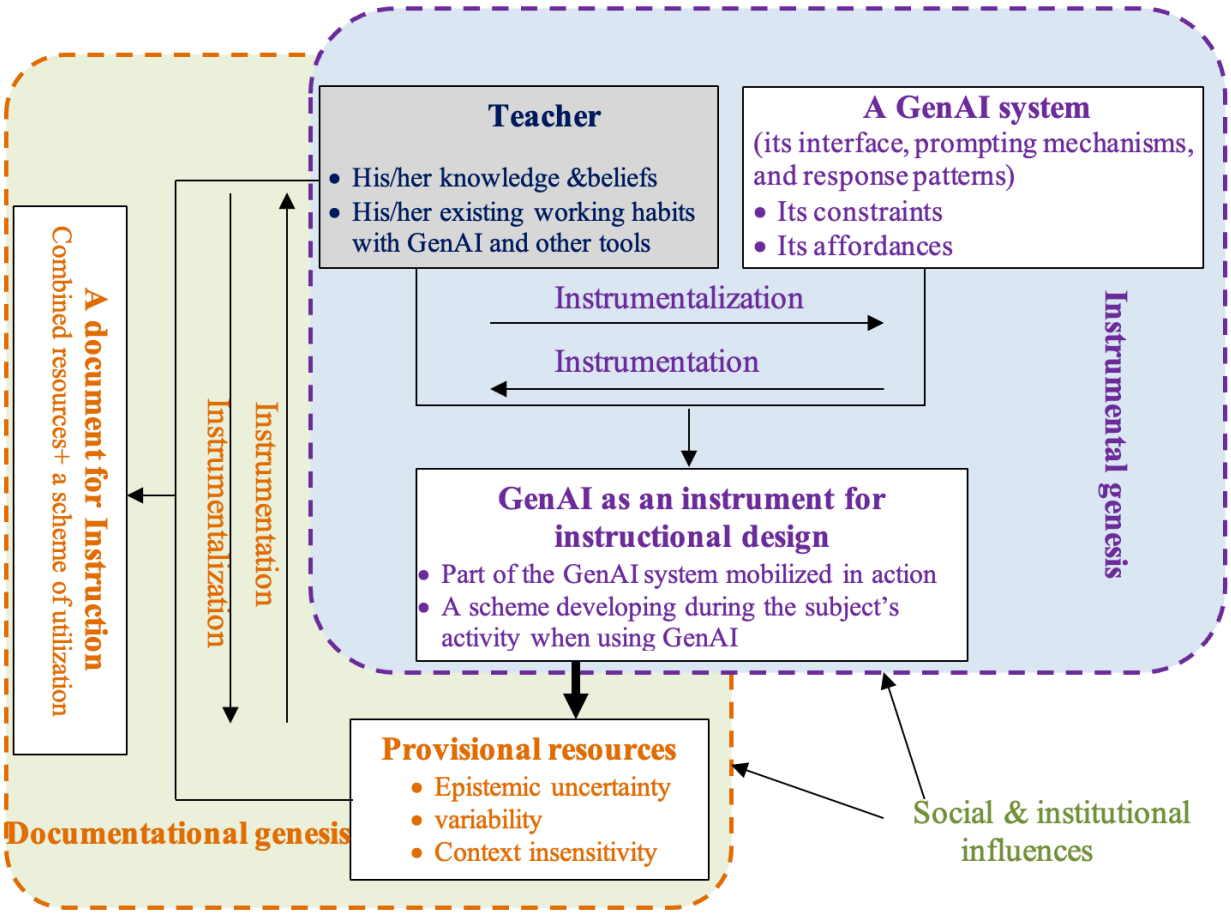

Figure 1: A Theoretical Framework for Understanding Teachers' Work with GenAI Through Instrumental and Documentational Genesis

A Theoretical Framework for Understanding Teachers' Work with GenAI

Integrating constructs in instrumental genesis and the documentational approach to didactics, this paper proposes a theoretical framework that conceptualizes teachers' work with GenAI as a dual genesis process: instrumental genesis and documentational genesis. Through instrumental

genesis, teachers develop utilization schemes that transform a GenAI system from an artifact into an instrument for instructional use. This instrumental activity produces AI-generated artifacts, conceptualized here as *provisional resources*, which require further professional work before instructional use. Through documentational genesis, teachers evaluate, adapt, and stabilize these provisional resources into instructional documents to be imbedded in their evolving resource systems. Figure 1 provides a visual representation of this dual genesis process.

Instrumental Genesis with GenAI

Instrumental genesis, originating in the theory of instrument-mediated activity (Rabardel & Beguin, 2005), describes the process through which an artifact becomes an instrument as users develop and appropriate utilization schemes for acting with it (Trouche, 2004; Trouche, 2018). An instrument is thus not the artifact itself, but the artifact together with the schemes that organize its use. Similar to many other digital technologies, a GenAI system, including its interface, prompting mechanisms, and response patterns, can be perceived as an artifact. Teachers' sustained interaction with this artifact gives rise to instrumental genesis, through which the GenAI system becomes an instrument for instructional design.

Instrumental genesis unfolds through the dialectical interplay of instrumentation and instrumentalization (Artigue, 2002). In instrumental genesis with GenAI, instrumentation refers to the ways in which the affordances and constraints of the GenAI system shape teachers' activities. The conversational interface of GenAI encourages iterative interaction and supports teachers' engagement in cycles of input, interpretation, and re-prompting. The non-deterministic response patterns of AI systems further shape teachers' activity by introducing variability and uncertainty, which requires teachers engage in comparison, selection, and evaluation of multiple outputs. Additionally, the speed and abundance with which GenAI produces outputs reorganize the temporal structure of instructional planning work. Teachers are less likely to be constrained by the need to create initial drafts and more engaged in activities, such as evaluating the mathematical correctness of AI-generated output, its pedagogical suitability, and its alignment with instructional goals. Through instrumentation, interaction with a GenAI system shapes how teachers engage instruction preparation without determining the outcomes of that work.

Instrumentalization refers to the process through which teachers appropriate a GenAI system to serve their instructional aims. In instrumental genesis with GenAI, instrumentalization primarily involves the development of utilization schemes for using a particular GenAI system. When interacting with a GenAI system, teachers learn to write prompts in which they might specify instructional goals, the focal mathematical concepts in a lesson, the types of representations to be used, and the levels of cognitive demand of mathematical tasks. They also develop strategies for how to handle AI-generated outputs, such as deciding when to accept responses, when to refine prompts, and when to abandon a line of interaction. Over time, teachers may establish techniques for using a specific GenAI tool for instruction, which might further shape how the GenAI system functions as an instrument in their instruction. It is also worth noting that when working with the same GenAI system different teachers may develop different utilization schemes.

The relationship between instrumentation and instrumentalization is dialectical. As GenAI shapes teachers' activities (instrumentation), teachers respond by adapting how they interact with the system (instrumentalization). These adaptations, in turn, modify how the system shapes teachers' subsequent activities. Instrumental genesis thus unfolds as a dynamic process in which teachers' utilization schemes and the functional use of GenAI co-evolve, which leads to the formation of GenAI as an instrument for instruction.

Emergence of Provisional Resources

The use GenAI introduces a unique challenge for examining technology use in mathematics education. Unlike mathematics-specific technologies such as computer algebra systems, graphing tools, and dynamic geometry software, GenAI does not merely mediate mathematics teaching and learning activities by providing computational capacities or multiple representations of a concept. Instead, it generates instructional artifacts that may later be used by teachers in their instruction. This generative nature is fundamentally important. From the perspective of instrumental genesis, a GenAI system initially functions as an artifact with which teachers may interact. Through sustained engagement, teachers develop utilization schemes that transform the system into an instrument for instruction purposes. When the artifact is generative, however, the outputs produced through interactions become possible resources for instructional use. These resources may include, for instance, mathematical tasks, lesson plans, mathematical explanations, or simulated student responses. These resources are neither authored in the traditional sense nor inherently pedagogically validated. They are produced through a probabilistic generative process whose internal mechanisms are a black box to its users.

I conceptualize these AI-generated instructional materials as *provisional resources*. They are resources in the sense that they are available for instructional use, but they are provisional because their epistemic status is yet to be established by teachers. Teachers need to engage in further professional work to determine their mathematical correctness, pedagogical appropriateness, and contextual relevance. The term "provisional" emphasizes that these resources are tentative and their legitimacy is subject to teachers' subsequent evaluation. The notion of provisional resources foregrounds the *epistemic uncertainty* that characterizes AI-generated materials. Unlike textbooks or curriculum-aligned digital resources, provisional resources do not carry implicit warrants of mathematical correctness, pedagogical appropriateness, and contextual relevance. Their legitimacy is not embedded in their origin but must be established through teachers' professional evaluation. As a result, provisional resources increase the demands on teachers' capacity to evaluate mathematical accuracy, pedagogical appropriateness, and contextual fit. In this sense, the notion of provisional resources makes visible forms of epistemic labor that often remain implicit when teachers work with resources from other sources (e.g., textbooks and resources from websites).

Provisional resources are also characterized by their *variability*. Because GenAI can generate multiple versions of a task or a lesson plan in response to the same or similar prompts, this variability might influence teachers' engagement with resources by encouraging comparison, selection, and refinement. The variability of provisional resources thus contributes to a shift in teachers' work from resource production or acquisition toward resource evaluation and curation.

Another defining feature of provisional resources is their incomplete alignment with instructional contexts. AI-generated resources are typically produced without access to knowledge of students from a particular classroom, classroom norms established by a teacher and students, curricular pacing and sequencing of a particular school, or institutional constraints. As a result, provisional resources often require substantial contextualization before they can be used productively in a particular classroom. This work of *contextualization* further underscores the provisional nature of these resources and the central role of teachers' professional knowledge.

To summarize, provisional resources are tentative instructional artifacts whose value and legitimacy are realized only through teachers' subsequent professional activity. This conceptualization of AI-generated artifacts provides a language for analyzing the distinctive

epistemic and professional challenges posed by teachers' use of GenAI and clarifies why teachers' documentation work becomes especially significant in AI-supported teaching.

Documentational Genesis with Provisional Resources

Documentational genesis provides a lens for analyzing how provisional resources are evaluated, adapted, and stabilized into instructional documents embedded in teachers' evolving resource systems. It refers to the long-term developmental process through which teachers transform resources into documents, which can be understood as the combination of resources, schemes of use, and the professional knowledge that underpins those schemes (Gueudet & Trouche, 2009; Trouche et al., 2018). Documentation work is not limited to the selection of materials for a particular lesson with a particular group of students. It encompasses the ongoing organization, adaptation, and re-use of resources across instructional contexts over time. When teachers work with AI-generated provisional resources, this documentation work becomes particularly visible, as the legitimacy of these resources cannot be assumed and must be established by teachers. Documentational genesis in the context of GenAI is shaped fundamentally by the epistemic uncertainty of provisional resources and thus the call for professional judgments to establish their instructional legitimacy.

As in instrumental genesis, the processes of instrumentation and instrumentalization in documentational genesis are closely connected, through which provisional resources are accepted, refined, or discarded. Instrumentation at the documentational level focuses on how provisional resources shape teachers' activities. The use of GenAI calls for teachers to foreground their professional evaluation and scrutiny of AI-generated materials. Given that AI-generated materials sometimes contain mathematical inaccuracies, inappropriate or incorrect representations, or misalignments with instructional goals, teachers need to assess their reliability and instructional usefulness. AI-generated materials thus call for teachers to focus their work on evaluating the epistemic legitimacy of provisional resources, such as checking mathematical correctness and considering their contextual relevancy for a particular group of students within a specific curricular sequence. In this sense, the characteristics of provisional resources (e.g., variability, opacity of generation, and lack of institutional validation) actively shape how teachers engage in documentation work. Instrumentation is also evident in how provisional resources invite comparison. Teachers may generate multiple AI-produced versions of a task or a lesson plan and compare them with one another, with existing curricular materials, or with the resources they have accumulated in the past. Such comparative work influences how teachers assess the quality of provisional resources. Through instrumentation, provisional resources shape both what teachers attend to and how they reason about instructional resources.

Instrumentalization at the documentational level describes how teachers actively transform provisional resources into documents for instructional use. For example, a teacher might revise an AI-generated task, rephrase a mathematical explanation, or modify a visual representation to better fit their classroom needs. Teachers may choose parts of a provisional resource, keeping what's useful and leaving out what isn't, or blend AI-generated content with materials from textbooks, previous lessons, or other sources. These choices shape how provisional resources are woven into classroom instruction. Instrumentalization also involves the development of schemes for working with provisional resources. Over time, teachers may establish stable ways of deciding when a provisional resource is sufficiently reliable for use, when further adaptation is needed, or when it should be discarded.

As in instrumental genesis, instrumentation and instrumentalization in documentational genesis are interrelated. Provisional resources shape teachers' documentation activity by

demanding evaluation and judgment, while teachers' actions reshape how those resources are handled. Through this dialectical interaction, some provisional resources are transformed into documents and therefore become part of teachers' resource systems, while others remain short-lived or are discarded completely. Documentational genesis explains how AI-generated materials move from tentative artifacts to durable components of instructional planning practice.

By analyzing documentational genesis with provisional resources, the framework clarifies how teachers' work with GenAI goes beyond interaction with the GenAI system itself. Instrumental genesis explains how teachers learn to work with the GenAI system as an instrument, while documentational genesis explains how teachers subsequently work with the products of that interaction. Together, these processes provide a coherent account of teachers' professional activities with GenAI.

It is important to recognize that instrumental genesis and documentational genesis are shaped by social and institutional conditions beyond each individual teacher's interactions with GenAI. The ways teachers use GenAI are shaped by school norms around curriculum, assessments, and technology policies, as well as by professional conversations within schools and teaching communities. Similarly, documentational genesis happens within shared resource systems, such as common instructional materials, teamwork, and group standards for instructional quality. Decisions about whether and how provisional resources are evaluated, adapted, and stabilized are therefore not only individual decisions. Instead, they are influenced by institutional expectations, accountability structures, and collaborative practices. Attending to these social and institutional dimensions highlights that teachers' work with GenAI is often situated within broader social contexts that shape how their utilization schemes emerge and develop over time.

Discussion and Conclusion

The framework proposed in this paper offers a theory-driven account of teachers' work with GenAI that centers professional activities such as the evaluation, adaptation, and contextualization of AI-generated materials rather than merely technological categorization. The framework conceptualizes teachers' engagement with GenAI through instrumental genesis and documentational genesis, offering a lens to examine how GenAI systems become meaningful in practice and how AI-generated materials are transformed into instructional documents. In this section, I elaborate on the theoretical contributions of the framework and outline implications for future research.

The framework extends instrumental genesis to account for the generative nature of GenAI. Much of the mathematics education literature on instrumental genesis has focused on tools that mediate mathematical activities without producing instructional materials themselves, such as computer algebra systems or dynamic geometry environments (e.g., Artigue, 2002; Trouche, 2004). In these cases, instrument-mediated activity primarily reshapes how users act on mathematical objects. GenAI differs in a fundamental way in that AI-mediated activity produces instructional artifacts that persist beyond the immediate interaction. By explicitly theorizing these outputs as provisional resources, the framework extends instrumental genesis to the use of GenAI. Provisional resources are understood as an outcome of instrumental genesis when the artifact is generative. The construct of provisional resources makes visible a form of professional work that is central to AI-supported teaching.

The documentational approach to didactics has emphasized that teachers' professional development is inseparable from their documentation work with resources and the evolution of their resource systems (Gueudet & Trouche, 2009). The framework proposed in this paper builds on this insight by showing how documentational genesis is reshaped when resources are

provisional rather than institutionally validated or pedagogically stabilized. AI-generated resources require teachers to engage in more intensive epistemic work, including validating mathematical correctness, determining pedagogical appropriateness, and assessing contextual fit. By articulating instrumentation and instrumentalization at the documentational level, the framework clarifies how provisional resources reorganize documentation work and foregrounds teachers' professional responsibility for instructional materials. In this sense, GenAI does not necessarily simplify teachers' work. Instead, it increases the need for teachers' professional judgment and makes documentation work more visible.

The framework also reframes contemporary discourse about the roles of AI in education. Recent literature has increasingly described GenAI as functioning in roles such as tool (Sarkar, 2023), hybrid actor (Dellermann et al., 2019), or partner/agent (Krakowski, 2025). While such descriptions capture aspects of how GenAI may be used in practice, they should not be interpreted as ontological claims about what GenAI systems are or can become. The framework developed here offers an alternative interpretation grounded in teachers' professional work. From this perspective, perceived roles of GenAI systems are not their inherent properties. Rather, they emerge from teachers' schemes across two levels of genesis: how teachers interact with the GenAI system through instrumental genesis and how they work with AI-generated materials through documentational genesis. GenAI may be experienced as a tool when teachers direct how they interact with the GenAI system and their documentation schemes emphasize rigorous validation and adaptation. It may also act as a hybrid actor when teachers allow GenAI outputs to shape instructional direction while retaining evaluative authority. It may be also perceived as an agent when teachers use AI-generated materials with limited scrutiny. In all cases, however, the locus of agency and responsibility remains with teachers' schemes of action. What changes is not the ontology of the GenAI system but the AI-mediated activity through which the system and its outputs are taken up. This reinterpretation allows the framework to critically examine GenAI use in mathematics teaching while maintaining a clear focus on teacher agency and epistemic responsibility.

The framework also provides important implications for empirical research. By theorizing teacher's work with GenAI as a dual genesis process and conceptualizing AI-generated materials as provisional resources, it provides a structured lens for designing studies that examine teachers' use of GenAI for instruction over time. Researchers can investigate, for example, how teachers' utilization schemes for interacting with GenAI systems develop, how these schemes shape the production of provisional resources, and how documentation schemes evolve as teachers evaluate, organize, adapt, and stabilize AI-generated materials. Longitudinal designs are particularly well suited to capturing how teachers' schemes change and how different dual genesis activities give rise to different patterns of GenAI use.

The framework invites a more cautious and theoretically grounded approach to claims about the transformative potential of GenAI use in mathematics education. By situating GenAI within established theoretical constructs, the framework resists both technological determinism and uncritical enthusiasm. It emphasizes that the educational significance of GenAI depends not on the capabilities of the technology alone but on how teachers' utilization schemes evolve in response to it. In doing so, the framework contributes to a growing body of scholarship that seeks to understand AI use in mathematics teaching and learning.

In closing, this integrated framework reframes teachers' engagement with GenAI as a form of professional work that unfolds through a dual genesis process. By conceptualizing AI-generated materials as provisional resources, the paper highlights the epistemic and pedagogical

judgments required to establish the instructional legitimacy of these materials. In doing so, it shifts attention away from technological characterizations of GenAI and toward the evolving schemes through which teachers evaluate, adapt, and stabilize instructional resources, which opens new directions for research on mathematics teaching and learning in AI-rich environments.

CONSTRUCTING MATHEMATICAL MEANING IN BLOCK-BASED PROGRAMMING: AN EXPLORATION OF HARD-CODING AND PARALLELISM

Shasha Zeng

biyao@hku.hk

While programming is advocated for fostering computational thinking in mathematics teaching and learning, students often face challenges when using programming tools such as Scratch to solve mathematical problems. This study analyzed task-based interviews with two sixth-grade students regarding the modelling of arithmetic sequences in Scratch. The findings reveal friction between mathematical intuition and computational concepts. Students resisted abstraction by manually calculating loop termination values rather than utilizing relational operators to define generalizable rules and struggled with computational parallelization. We conclude that a working Scratch program does not necessarily imply conceptual mastery, and educators should support students in unpacking the logical structures and mathematical relationships underlying programming artifacts.

Keywords: Computational Thinking, Computing and Coding, Problem-Solving, Algebra and Algebraic Thinking

Background

Constructionism and Learning with Object

This study is grounded in Papert's (1980) theory of constructionism. According to Papert's constructionism, learning is optimized when a learner is engaged in the construction of an external public entity, object, for example, a computer program or the produced outputs. A computer program can serve as an object-to-think-with that enables and supports students in applying and practicing abstract mathematical concepts and problem-solving strategies. In the Scratch programming environment, for example, students can have access to the program scripts and outputs on the interface at the same time, and they can manipulate, reuse, and remix the scripts to achieve certain mathematical goals. Programming also supports a safe learning space where mistakes are common and acceptable. When a student's program does not yield the desired outcomes, the visual feedback is instantaneous and non-judgmental for the student and motivates them to improve the program. Students are encouraged to explore alternatives, modify unproductive choices, and improve mathematical reasoning and understanding during the problem-solving process (Resnick et al., 2005).

Moreover, Papert (1980) introduced the concept of syntonic learning, which refers to learning that resonates with the learner's self-perception. For example, a programming tool such as LOGO (a robotic or on-screen turtle that draws lines) facilitates body syntonicity, allowing students to project themselves physically into the computational object. By imagining, "If I were the turtle, how would I move?", students engage their own spatial and bodily awareness to navigate mathematical problems, thereby grounding abstract mathematical reasoning in that computational object. The object simultaneously represents a "resonance" between external forms and concepts and what students know about themselves (Papert, 1980; Watt, 1998).

Challenges in Integrating Computational Thinking and Mathematical Reasoning

Computational Thinking (CT) in K-12 education is increasingly conceptualized as an interplay, a reciprocal relationship in which CT is a vehicle for mathematical meaning-making

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

(Weintrop et al., 2016). However, Cui and Ng (2021) conducted an empirical study involving eight students in Grades 5–6. They demonstrated that the challenges faced by primary students were compounded by the necessity to learn in a block-based programming environment while simultaneously applying mathematical concepts and problem-solving skills within that context. Cui and Ng (2021) also found that a programming-enhanced environment does not guarantee mathematical engagement in a programming-enhanced environment. They concluded this as a potential conflict in which the student engaged in trial-and-error or tinkering with the computer interface in the programming environment. This behavior is not a mathematical reflection of the deep-thinking strategy; rather, it is a superficial CT strategy that only partially replaces it. This means that the challenge for the teacher is to prevent students from exceeding this superficial tinkering stage in real mathematical teaching when incorporating programming-enhanced mathematics problem design.

Despite increased advocacy for the inclusion of CT in mathematics classrooms, the specific cognitive mechanisms that promote or hinder this confluence remain under-represented. Ye et al. (2023) performed a systematic analysis of previous empirical studies and found that in the fields of mathematics and STEM, more empirical research is needed to prescribe ways that would help educators incorporate CT in formal K-12 curricula. Research on CT is in its early stages, with few studies specifically addressing the importance of programming in helping particular mathematical learning content. Therefore, this study aims to clarify the underlying difficulties that can stem from mathematics and CT in the programming setting. Thus, this study addresses the following question: What challenges do upper-primary students perceive in their mathematical reasoning in a block-based programming environment?

Theoretical Framework

To analyze the specific challenges students face, this study draws on Brennan and Resnick's (2012) computational thinking framework, focusing on the unique affordances and demands of block-based programming environments. Given that visual and structural features significantly shape how learners engage in computational thinking on programming platforms, we operationalized the interplay by focusing on the interplay between two different practices drawn from Brennan and Resnick's framework dimensions, including computational concepts and computational practices, and recontextualizing them for a block-based programming environment. The first is testing, debugging, and "hard-coding." Testing and debugging are core computational practices (Brennan & Resnick, 2012). For this study, the students used computational models, such as the Scratch program, to understand abstract mathematical concepts and used their problem-solving strategies to find and test solutions by reusing and remixing the program while applying mathematical reasoning. Cui and Ng (2021) argued that during troubleshooting and debugging processes, students normally use mass mental calculations to execute the arithmetic and simply treat the computational tool as the output display. Therefore, building on Cui and Ng (2021), we define "hard-coding" as a problematic debugging practice in which students bypass computational logic.

Furthermore, how students transform mathematical reasoning into computational concepts, such as iteration, variable, and parallelism, is still under study (Brennan & Resnick, 2012). For example, in traditional mathematics, a variable denoted as x serves as an abstract placeholder. This abstraction often poses challenges for beginners who struggle to shift their perspective from arithmetic, where math is a series of calculations, to algebra, where math involves abstract structures and relationships. Conversely, in block-based programming, a variable serves as a tangible container that can be instantiated, invoked, and visually traced instantaneously on the

Scratch interface, especially when students remix the programs. Dragging variable blocks into the coding script converts the abstract notion of a variable into a concrete, manipulable visual container. Unlike mathematics, the Scratch programming environment integrates the concept of parallelism, enabling the execution of sequences of instructions concurrently. This capability facilitates parallelism across various objects, such as scripts for different sprites within the same program (Brennan & Resnick, 2012). Because parallelism is absent from traditional mathematics curricula, we utilized this construct to analyze the cognitive hurdles students face when translating linear mathematical reasoning into concurrent computational concepts.

Methods

Research Design

This study used a qualitative case study method to examine how students reasoned mathematically and computationally while solving programming-based mathematical tasks. Two semi-structured task-based interviews were conducted with a pair of sixth graders (aged 11–12). They worked together in the interview, collaborating to complete tasks that required them to create two arithmetic sequences and find the point at which the two sequences intersected. The researcher used a semi-structured interview protocol to support students' exploration and collaborative problem-solving rather than providing direct solutions. Open-ended questions like "Why do you think so?" and "Can you show me what you mean?" were used to encourage students to think aloud and clarify their thought processes during discussions.

Participants

The study involved a pair of students, Zoe and Daniel (pseudonyms), from a public primary school in the Chinese mainland. We used purposeful sampling to select students who fulfilled the profile of novice programming learners, who had basic fluency with Scratch, which they learned through regular computer classes at their school, but who lacked advanced computational concepts and problem-solving practices. The selection criterion was to ensure that the study could apply mathematical reasoning and problem-solving strategies to learn arithmetic sequences in a programming-enhanced environment, rather than trying to test already known ideas.

Task Design

The main task was structured into three sub-activities to progressively scaffold students' understanding from operationalizing simple recursive rules to modelling and simulating arithmetic sequences (see Figure 1).

Activity 1: Technical scaffolding for variables and lists. A warm-up task was conducted to reduce the interference of technical challenges. Students were introduced to the variable and list blocks needed to log data: the variable blocks were used to store the current value, and lists were used to store a history of variable values as the program ran. The student dyad was asked to create a simple sequence of integers from 1 to 10. This stage ensured students were convinced that a loop needs an initialization, using the blocks "set [variable] to [1]" and "change [variable] by [1] step."

Activity 2: Mathematical scaffolding for describing the first term and the common difference. The students were asked to remix their program to generate specific sequences of 3, 6, 9, … and 3, 8, 13.… The researcher explicitly guided students to map the mathematical concept of the first term a_1 and the common difference d to the coding. Furthermore, to challenge the robustness of their model, students were tasked with creating a sequence with an initial term greater than 30 and ending with the first negative number. Students needed to conceptualize the pattern as a negative integer value using the "change variable by [ ]" block to bridge the gap between subtraction and adding negative integers in the loop.

Activity 3: Influencer battle simulation. This activity asks students to simulate a competition game that models a social media scenario. The scenario is presented as follows: two videos compete for "likes:" one is the "sleepy cat," who starts with high initial popularity with 500 likes but grows 10 likes per hour. Another is the "dancing cockroach," who begins with low initial popularity of 50 likes but grows 55 likes per hour. Students were asked to create a Scratch program that simulated the hourly growth of both videos and determined the number of hours when the two videos had the same number of likes. Through their exploration and discussion, students were expected to recognize that while the initial value of the "dancing cockroach" video is lower, its greater rate of change will enable it to catch up with the "sleepy cat." To support peer collaboration, the students worked in pairs and were encouraged to use a think-aloud approach in the interview. This open collaborative environment allowed them to freely discuss their mathematical reasoning, co-construct computational logic, and jointly solve problems, which facilitated the subsequent exploration of their collaborative routines.

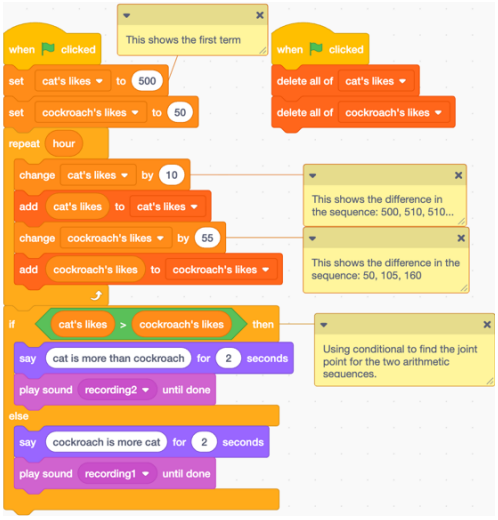

Figure 1: The Sample Script for the Increasing and Decreasing Sequences

Data Collection and Analysis

In the task-based interview, the children's programming activities on the computer were recorded on screen, and their written work was captured by another camera next to their desk. After the interviews, the videos were transcribed word-for-word, including all gestures, on-screen actions, and interactions. We analyzed the students' reasoning and practices using NVivo, along with researchers' reflective notes to observe changes in their thinking processes. We used thematic analysis (Braun & Clarke, 2006) to analyze students' discourses and problem-solving practices. We focused on moments of confusion, troubleshooting, and debugging, where the program had issues and students worked together to fix them. The coding process had two phases: first, creating initial codes based on students' expressions, and second, developing initial themes. Inductive coding revealed new insights into students' real problem-solving experiences. Deductive codes were based on Brennan and Resnick's (2016) framework, which includes computational practices, such as using computational models for testing and debugging, reusing, and remixing, and computational concepts, such as sequences, loops, and parallelism.

Results

We report on the interaction between Zoe and Daniel, who worked on three programming-based mathematical activities. We chose this case because their exchange showcases how their mathematical reasoning conflicted with the computational concepts and practices in a block-based environment. In this section, we outline their reasoning process through two separate excerpts from the task-based interview.

Excerpt 1: The Cognitive Gap Between Arithmetic Operations and Algorithmic Thinking

In Activity 2, students were asked to create a decreasing arithmetic sequence from a number greater than 30 to the first negative number. As shown in Figure 2, students realized that every term should be smaller than its previous term by their mathematical intuition and thus required a negative common difference. However, while establishing a termination condition for the conditional loop, they hard-coded a specific termination value of "–4" by calculating it rather than using a logical operator in the loop. Hence, the program went into an infinite loop because the computer was unable to stop the process if there was no –4 in the result list. The excerpt is shown below:

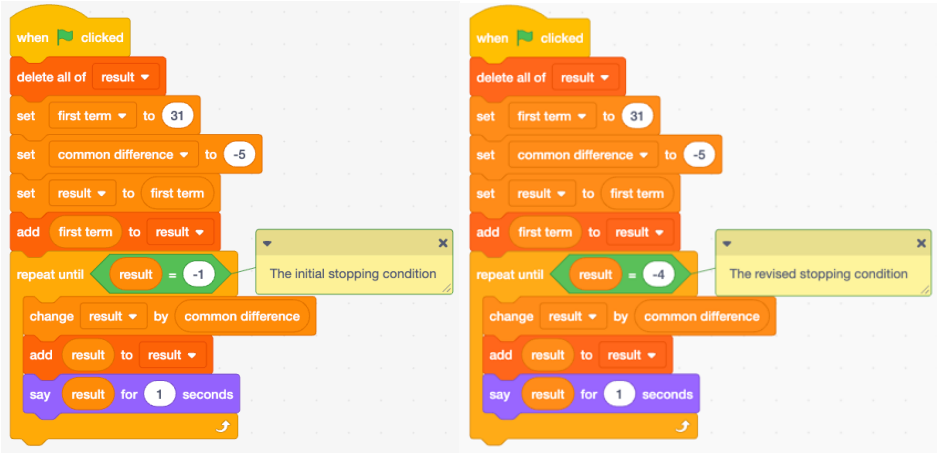

Figure 2: Hard-Coding the Decreasing Arithmetic Sequence

[Daniel sets the common difference to –5, the first term to 31, and sets the repeat loop until result = –1]

Daniel: Hmm? No, that's wrong. I need to set it to –4.
Interviewer: It must end with the first negative number.

[Students were working together to debug the program.]

Interviewer: Is that correct? I thought Daniel was doing fine just now. At first, This repeat block was set to end with –1. Why did you change it to –4?
Daniel: I made a very basic mistake at the beginning.
Zoe: No, he just calculated it wrong.
Zoe: Because it has to repeat until the first negative number.
Interviewer: So the list we see must go up to the first negative number.

This excerpt illustrates the clear interaction between mathematical reasoning and computational thinking. The students correctly identified the inverse relation needed for the

sequence. However, Daniel used a mental calculation to set the loop stopping condition to –1, but the outcome mismatched with what he intended, which illustrated a lack of abstraction in the loop stopping condition. When Daniel realized that he had made a calculation error, he carried out the calculation mentally to identify that –4 was the first negative number and used this to set up the stop repeat condition. Instead of leveraging the computer's work to automate the process, the student hard-coded a solution. He relied on his own mental math to determine the exact stopping condition, essentially doing the work for the computer rather than letting the program calculate it.

Excerpt 2: From Parallelism Confusion to Serial Logic

In Activity 3, Zoe and Daniel modelled the growth in likes for the "sleepy cat" and "dancing cockroach" competition game. Initially, the students created two separate programs triggered by the same "when this sprite clicked" event (see Figure 3). In the following excerpt, the participants attempt to synchronize the arithmetic progression of two sprites.

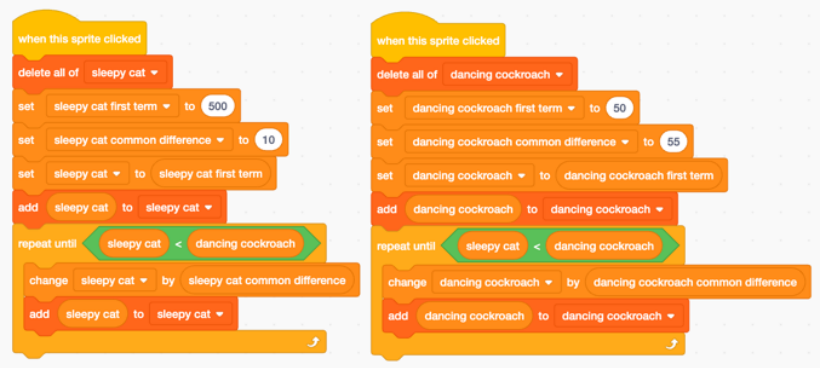

Figure 1: Two Separate Programs Created by Students in the Activity 3

Zoe:	It can keep moving, but it won't stop. It won't stop.
[…]	
Interviewer:	Is there a stop at the very bottom?
Daniel:	No, the [list] length is 200,000.
Interviewer:	Why? Because you did not define the loop [condition].
Zoe:	Right.
Daniel:	You can't scroll to the bottom.
Interviewer:	If you find that running these two in parallel is causing issues, you can try merging them. But be careful.
Zoe:	Oh, merge! Anyway, these three blocks need to move over. The first term is wrong here, this is for dancing cockroach. These three definitely need to be overcome; they are the initial information. Bring them here… and then set the sleepy cat… I'm trying, okay? [look at Daniel]
Daniel:	There's an empty spot down here.
Interviewer:	Does it stop now?
Zoe:	It stopped.

[Zoe and Daniel were very happy because it worked this time.]

Interviewer:	Look, the cat starts at 510, ending at 610. Okay, dancing cockroach stopped at 655. So that means it took 12 hours for it to stop.
Zoe:	I am so awesome!
Daniel:	Why were there so many problems before?
Zoe:	You mean why was there so much stuff before?
Daniel:	I mean, when we did those two separately earlier, why were there so many problems?
Zoe:	Yeah, why couldn't we succeed when they were separated? [Both students were confused on the parallelism problem.]

This excerpt highlights an important disparity between students' syntactic success and their conceptual understanding. Although they successfully fixed the bug by following the interviewer's hint to "merge" the two scripts into one, their final discussion revealed that they did not actually understand how parallelism worked. They remained confused about why their original, separate scripts conflicted and failed to work together.

Daniel's last question, "I mean, when we did those two separately earlier, why were there so many problems?" demonstrated that their decision to switch from parallel to serial execution was based on trial and error rather than a deep understanding of the codes. The students struggled to conceptualize how two independent loops interacted in real time when evaluating a shared condition, such as whether the sleepy cat was smaller than the dancing cockroach. The parallel scripts were viewed as two independent worlds rather than considering the need for synchronization of the state of the shared variables when two or more threads relied on them.

Transitioning from Arithmetic to Algebraic Thinking through Block-based Programming

More importantly, we argue that the programming environment gradually served as a mediator in the transition from arithmetic logic to algebraic rationale. When confronted with a query regarding the long-term result, the pupils abandoned the immediately prior emphasis on total quantity calculation and adopted Zoe's own use of the code as an epistemic practice, directing participants immediately to the script itself: "[The] cat begins high (points to set to 500), but it's slow (points to change by 10). [The] cockroach begins low [but] this block (change by 55) equals much bigger." This suggests that the visual design of block-based programming acts as a helpful mediator between arithmetic and algebra. Specifically, the clear distinction between the "set to" block (representing the starting value, or intercept) and the "change by" block (representing the growth rate, or slope) helps students move beyond simple mental arithmetic calculations to understand the mathematical principles governing the system.

Discussion and Conclusion

This study examines the interaction between mathematical reasoning and computational thinking during modeling simulation tasks. The findings indicate that while block-based programming environments like Scratch facilitate simpler algorithmic expression, they expose a specific challenge when students' mathematical fluency can interfere with computational thinking when the two domains require different types of reasoning. First, mathematical fluency can hinder computational thinking if certain CT practices are missing. For example, in the arithmetic sequence task in Excerpt 1, students identified the mathematical relationship for a negative difference correctly. However, they relied heavily on mental calculations, which prevented them from engaging in abstract thinking (Weintrop et al., 2016). As Papert argued that ''computer presence could contribute to mental processes not only instrumentally but in more essential, conceptual ways, influencing how people think even when they are far removed from

physical contact with a computer'' (Papert, 1980, p. 4). By hard coding the loop termination value, students viewed the computer as a static tool rather than an interactive problem-solving partner. This aligns with research showing that novice programmers struggle to make the cognitive shift from calculating the arithmetic answer to defining the rule (Noss & Hoyles, 1996), a crucial step for both computational algebraic thinking. Second, challenges with computational parallelization were noted in Excerpt 2 (Brennan & Resnick, 2012). In mathematics, two functions change simultaneously and continuously, but in computing, simultaneous execution is hidden in the programming environment. Daniel's frustration with why parallel scripts failed and merged scripts worked indicates that students didn't grasp the parallelism issue. This suggests that without explicit instruction bridging mathematical and computational thinking, students might see parallel scripts as separate mathematical entities rather than interacting computational processes. These findings point to a gap that teaching practices need to explicitly address directly, specifically how students move from mathematical formulas to algorithmic thinking. Instead of assuming that writing code will automatically develop algebraic thinking, educators should focus on using relational operators like "smaller than" or "bigger than" instead of specific values to define loop-stopping conditions. Additionally, teachers should differentiate between how mathematics works simultaneously and how code runs sequentially. Clarify this helps students stop relying on trial and error and guessing and instead integrating mathematical and computational thinking.

Acknowledgments

The authors would like to express their sincere gratitude to the students who took part in this study, these valuable contributors gave the time to share their reasoning and experiences that made this research possible. Special thanks to Professor Biyao Liang for her invaluable guidance, mentorship and feedback throughout the development of this study.

IN-SERVICE MATHEMATICS TEACHERS' PERCEPTIONS ABOUT USING AI IN MATHEMATICS EDUCATION

Zareen Gul Aga
James Madison University
agazg@jmu.edu

Youngjun Kim
Montclair State University
kimy8@montclair.edu

As generative artificial intelligence (Gen AI) tools such as ChatGPT, Gemini, and Copilot become increasingly integrated into K-12 classrooms, understanding teachers' perceptions is critical. Guided by the TPACK framework, this action research study examined how six in-service mathematics teachers engaged in a professional learning community (PLC) focused on AI use in mathematics education. Data included reflections, AI-generated lesson artifacts, and PLC transcripts. Findings indicate a shift from cautious optimism to a more nuanced view of AI as a productive yet incomplete collaborator. While teachers valued AI for efficiency and idea generation, they emphasized the need for professional judgment, AI literacy, and sustained professional development to ensure rigorous and equitable mathematics instruction.

Keywords: Professional Development, Technology, AI Integration

Purposes of the Study

Artificial intelligence (AI) is already being integrated into K-12 education through tools—such as ChatGPT, Gemini, and Copilot—that teachers use to support instructional planning, develop instructional materials, and promote student engagement (Holmes et al., 2019; Pedró et al., 2019; U.S. Department of Education, 2023). Some examples include generating lesson plans, crafting contextualized mathematical problems, producing mathematical stories, and creating visual representations. These can inform how teachers design tasks, represent mathematical ideas, and connect mathematics to meaningful contexts.

As AI becomes more prevalent in classrooms, scholars and policy makers emphasize the importance of developing AI-literacy skills among K-12 students (Long & Magerko, 2020; Pedró et al., 2019; Touretzky et al., 2019; U.S. Department of Education, 2023). AI literacy involves understanding how AI systems generate outputs, and critically evaluating AI limitations, ethical implications, and potential biases (Long & Magerko, 2020; Pedró et al., 2019). In mathematics classrooms, AI literacy is especially relevant when students' interact with AI-generated responses that may influence mathematical reasoning and sense-making.

There is a need for teacher professional development (PD) to help teachers support ethical and effective AI-use in K-12 classrooms which can directly influence students' development of AI-literacy skills (Ding et al., 2024). Learning about teachers' perceptions of AI in education can help to facilitate their learning (Aga et al., 2024). Further, there is a technology divide not just due to school resources but also due to teacher knowledge of technology, in particular AI use (Tan & Tang, 2025). To learn about teachers' mindsets and skills towards AI use we investigated how 6 in-service teachers engaged in conversations about AI use in mathematics education and developed activities for AI based mathematics instruction. Our research question was: *What are mathematics in-service teachers' perceptions about using AI in mathematics education?*

Theoretical Framework

The Technology, Pedagogy, and Content Knowledge (TPACK) framework, developed by Koehler and Mishra (2005, 2009), extends Shulman's (1986, 1987) notion of pedagogical content knowledge by incorporating technology into teachers' professional knowledge. Rather

than treating technology as an add-on, TPACK conceptualizes teacher knowledge as an integrated system where technology, pedagogy, and content dynamically interact. This framework is relevant for examining mathematics teachers' perceptions of AI, as AI tools increasingly influence instructional decision-making (Holmes et al., 2019), student engagement (Steenbergen-Hu & Cooper, 2014), and sense-making (Drijvers, 2015; Pedró et al., 2019).

Within TPACK, content knowledge (CK) refers to teachers' understanding of mathematical concepts and practices; pedagogical knowledge (PK) encompasses instructional strategies, discourse facilitation, assessment, and support for diverse learners; and technological knowledge (TK) includes familiarity with digital tools and ability to adapt to emerging technologies. In AI contexts, TK includes operational skills, understanding how AI systems function (e.g., automated feedback, generative problem creation, and adaptive learning) and recognizing their limitations. TPACK represents teachers' integrated understanding of how AI can support mathematically meaningful and pedagogically sound instruction.

The intersection among these domains is foundational to understanding TPACK: technological content knowledge (TCK) involves how AI transforms mathematical representations and problem-solving pathways, while technological pedagogical knowledge (TPK) addresses how AI reshapes instructional practices, including scaffolding and formative assessment (Koehler et al., 2013).

A defining feature of TPACK is its emphasis on context. Teachers' perceptions of AI are shaped by curricular demands, classroom norms, ethical concerns, and beliefs about student agency and reasoning (Selwyn, 2019). Research suggests that teachers may perceive advanced technologies as undermining the integrity of mathematical reasoning or diminishing teachers' instructional role unless they are supported in examining how technology intersects with pedagogy and content (Graham, 2011). TPACK is a useful theoretical lens for investigating mathematics teachers' perceptions of AI integration by highlighting the complex, situated knowledge required to leverage AI in ways that promote deep mathematical understanding.

Methods

We employed action research methodology (Stringer & Aragón, 2020) to examine and improve practice through systematic inquiry within a professional learning context. Action research supports practitioners in investigating their own settings and generating actionable knowledge to inform instructional improvement (Mertler, 2009). The meetings took place virtually during the Fall 2025 semester and were facilitated by a mathematics teacher educator (MTE) at a public university in the Mid-Atlantic U.S.

Our participants included six in-service teachers (five at the high school level and one at a community college) who engaged in four PLC meetings to discuss AI use in mathematics education. We analyzed four PLC meeting recordings, written reflections about AI in mathematics education, and teacher-developed AI activities. We conducted open coding (Corbin & Strauss, 2014) of PLC meetings and reflections to look for emergent themes regarding perceptions about AI use in mathematics education. We also employed thematic analysis (Guest et al., 2011) to examine patterns in teachers' pedagogical use of AI.

Findings

Initial Ideas about AI in Mathematics Education

PLC data revealed a pattern of cautious optimism toward integrating generative AI (Gen AI) in mathematics education. Many teachers described using AI to develop lesson plans, engaging tasks, examples, datasets etc. AI was frequently characterized as a time-saving tool and a helpful

"jumping off point" for instructional ideas. Participants also viewed AI as a potential personalized tutor providing students with alternative explanations and additional practice.

Participants expressed significant concerns about students' overreliance on AI. A dominant theme was the tension between AI as a support versus a shortcut. Teachers worried about student AI use to obtain answers without developing conceptual understanding. Issues of cheating, diminished critical thinking, and unclear boundaries for acceptable use were repeatedly noted. Some participants expressed hesitation about becoming dependent on AI in their own teaching. Overall, they perceived AI as a promising yet complex tool, valued for efficiency and support, but raised concerns about maintaining deep mathematical thinking and responsible AI use.

Engagement in Using GenAI to Develop Lesson Plan or Activity

Engagement in PD (e.g., the calculator activity) was eye opening for teachers and they learned about the predictive nature of AI (PLC meeting 1). Teachers worked in teams to develop mathematics activities throughout the semester. They used caution when considering student engagement with AI, as a thought partner. Teachers in their teams decided on learning goals and math standards, considered implementation strategies and questions they would need their students to answer. They considered if their students would use AI to learn a new concept or critique AI work using existing knowledge. Such questions allowed the teachers to consider what features can allow students to engage with AI as a supportive collaborator (PLC Day 3).

Teachers also learned how to use AI to develop comics with the goal to develop students' mathematical identity. Teachers used the comic generation capacity of GenAI tools to consider ideas such as using comics to discuss social justice issues, helping students learn about practical applications of mathematics, financial literacy, using comics to help students engage in mathematical discussions, and making word problems more accessible (PLC Day 4).

Reflection on Using GenAI After Developing Lesson Plan or Activity

After using AI to generate a mathematical activity, teachers described AI as a collaborative partner and idea generator, rather than a replacement for teacher expertise. Participants reported using AI iteratively. They began with an initial prompt and refined outputs by adding specific conditions, parameters, and revisions. Several characterized AI as a "starting point" or "curriculum developer" that helped structure lessons, suggest pacing, generate differentiation strategies, and propose student engagement ideas. Teachers appreciated AI's efficiency, its ability to generate ideas they had not previously considered, and its responsiveness to revisions. Participants noted that AI was helpful for brainstorming, organizing lesson components, and quickly producing a draft that could be improved through professional judgment.

At the same time, teachers emphasized the need for critical evaluation and adaptation. Common concerns included lack of detail, limited alignment with specific learner needs, superficial engagement with mathematical content, and unrealistic classroom assumptions. Participants reported that AI-generated materials were often "thin" in instructional depth and required substantial refinement to ensure the integrity of conceptual understanding and contextual relevance. Several also noted that AI lacked knowledge of their particular students' interests and classroom dynamics. Overall, teachers positioned AI as a productive but incomplete collaborator, which is valuable for efficiency and idea generation, yet dependent on teacher expertise to ensure quality, relevance, and meaningful mathematical learning.

Questions, Concerns, and Ideas from PLC Meetings

Teachers shared that schools are in the process of developing AI use policies. Some teachers mentioned having access to AI chatbots in schools, but student AI use is not allowed. Districts are considering pros and cons of AI aided education and proceeding with caution (PLC Day 3).

Teachers mentioned using AI to generate ideas for planning instruction (e.g., differentiation, real world activities, etc.) (PLC day 2). They also mentioned using AI for administrative tasks like writing letters of recommendation, generating assignments for students (PLC meeting 1).

We found a variation in teacher knowledge, skills and their familiarity with AI tools. Not all teachers were at the same level of comfort or experience using AI based educational tools or using GenAI in general. Some teachers were scared of using AI and mentioned that they are not "tech people". All teachers needed guidance to engage with AI. The PLC allowed an opportunity for teachers to discuss AI use in a safe space. Some teachers compared it to calculators; others compared it to search engines such as Google (PLC meeting 1). There is a need to provide PD for teachers to level the playing field for students. During the PLC, teachers worked in collaboration with other teachers. Such collaboration can help them brainstorm ideas and critique AI work. In particular, the access divide may decrease when teachers scared of technology, work with teachers who are experienced and accepting of new technology (PLC Day 2).

Teachers also provided recommendations for student AI use. They brainstormed what AI skills students need (PLC meeting 1) and expressed caution about student AI use (PLC Day 2). Teachers perceived challenges about students using AI to learn math. This included language barriers for ELL students, if they would be able to communicate as well as native English speakers, if students' literacy skills would cause a barrier in developing prompts, time and pacing concerns, and student motivation concerns. Teachers stressed that students are not used to learning mathematics by reading from books, they see worked out solutions in classroom or work with their peers to discover math concepts. However, in all these cases the teacher is present for guidance. Independent student engagement with AI would depend on many factors that can develop an access and ability divide both for learning math and using AI (PLC Day 3).

Discussion and Conclusion

Findings indicate that teachers' perceptions of GenAI in mathematics education shifted from cautious optimism to a more nuanced view of AI as a productive yet incomplete collaborator. Initially, teachers valued AI for efficiency, idea generation, and differentiation, while expressing concerns about cheating, overreliance, and reduced conceptual understanding. In subsequent lesson design experiences they positioned AI as a drafting partner that required iterative prompting, critical evaluation, and professional judgment to ensure conceptual understanding and alignment with student needs. PLC discussions also revealed variability in teachers' confidence and familiarity with AI, suggesting a divide rooted more in knowledge and mindset than access. The collaborative PLC structure helped mitigate this gap through experimentation, dialogue, and reflection, supporting intentional design of AI-supported tasks that emphasized learning goals, equity considerations, and use of AI as a thought partner rather than a shortcut.

Overall, teachers perceived AI as a promising instructional tool for planning, differentiation, and engagement, but also as an instructional tool that requires careful oversight to maintain deep mathematical thinking and equitable access. These findings carry important implications for policy and professional learning. As districts develop AI-use policies, guidance should move beyond restriction toward clarifying responsible, instructional use for both teachers and students. Sustained and collaborative PD is essential to strengthen teachers' AI literacy and reduce disparities in readiness. Moreover, since teachers identified concerns related to language barriers, prompt-writing skills, motivation, and overreliance, AI integration should include explicit instruction in student AI literacy. Without intentional scaffolding and aligned policy support, the use of AI risks widening existing inequities in mathematics learning rather than enhancing it.

In this report, we describe how seven secondary mathematics teachers recruited from public and private schools across a rural northeastern state imagined integrating an immersive virtual reality environment into their teaching practice. During an interactive focus group, secondary teachers tested a multiplayer immersive virtual environment and then were interviewed about their explorations of that environment. Participants were told that the goal of the session was to dream big dreams – i.e., they were urged to set aside concerns about time, resources, and curricular constraints, and to focus on the mathematics that would be possible to teach in the environment. In this report, we provide a design overview of the environment (TriO), describe teachers' activities within it, and report teachers' initial ideas about the mathematical learning opportunities it afforded.

Keywords: Technology, Geometry and Spatial Reasoning

Introduction

New technologies continually transform the kinds of mathematical explorations we can conduct in and outside of the classrooms. From the introduction of digital calculators in the 1970s, to the emergence of computer algebra systems, dynamic geometry software such as GeoGebra and Desmos, teachers and students adapted to the changing landscape of possibilities. In the past three decades, we have seen the rise of extended reality (XR) technologies being used to explore mathematical ideas from new lenses (Kaufmann et al., 2000; Dimmel et al., 2021; Walkington et al., 2025). Here, we imagine the possibility of transforming how we understand and explore space, an endeavor that has been elusive in classroom mathematics. Action-based design is a genre of embodied design that builds on learners' perceptuomotor capacity to develop new routines for solving a sensorimotor task (Abrahamson, 2014). By creating perceptuomotor schemas to engage in the embodied task, learners connect their intuitive actions to the formal concepts. *TriO* (Dimmel et al., 2025) is a virtual environment that tasks three participants with coordinating joint, distributed and asymmetrical action. Distributing the cognition across multiple people and a shared artifact can yield a combined cognition that no single person holds (Hutchins, 1995).

Environment Design

TriO extends the design of OЯTHO—a two-player, touch-based interactive digital game, wherein players work together to navigate a digital ball around a digital track by controlling either its vertical (Player 1) or horizontal (Player 2) location (Potega vel Żabik et al., 2024) to encompass 3-dimensional space. It is a fully three-dimensional, visually immersive, interactive

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

environment that was designed for simultaneous exploration by multiple immersed learners. This virtual environment features a small widget made out of three orthogonally intersecting discs, such that the position of the widget is controlled by the three color-coded handles. The goal is to coordinate the widget to touch the numbered starbursts to activate them. (Figure 1). Each handle controls a single degree of freedom of the widget's location in space along the x, y, or z axes (Figure 2). Three players working collaboratively can freely move the widget along any (continuous) path in R3. Participants could also activate 2D rectangular walls (Figure 3), which are sections of a plane that is orthogonal to the axis they controlled. Each wall is the same color as its corresponding handle, is semi-transparent, and is etched with coordinate lines.

Figure 3 [Right]: Semi-Transparent Walls and the Coordinates of the Widget

Data Collection and Analysis

We invited seven teachers for a three-day workshop (August 2025) in a rural northeastern state. This workshop marked the second year of our data collection and playtesting sessions we conducted with teachers, and only one teacher attended both years. The teachers participated in a series of focus groups in virtual environments. A member of the IMRE lab was present in the focus group to guide the discussion. The teachers were positioned as participant co-designers of the environments. The focus group sessions were both audio and video recorded.

Authors watched and highlighted portions of the video clips where teachers had productive struggles, made remarks on how to modify the environment for classroom use, or demonstrated understanding of mathematical mastery. We here selected two slices from a holistic view of the activities in *TriO* and their potential as a learning tool.

Teacher Experiences

Discursive Challenges in *TriO*

One of our teacher participants, Mike, noted the struggle of developing a common language for collaborating in *TriO.*

> Mike: I don't know if you've ever been driving with someone and they say, "Turn that way." You're like, "What way?" And they point out the windshield and say, "That way" and try to communicate. Well from my perspective, I don't know if we're pointing to the right or left. So that's very similar here and much lower stakes. We can maybe develop some

positive or negative perspectives because if I say left, left doesn't mean the same from standing across from perspective. So being able to develop that type of communication skills and perspectives is very important for these puzzles.

Mike is aware that saying "go right" or "go left" can be confusing to his teammates as they might be facing a different direction. Instead, he said "The blue plane needs to come towards me," while placing his finger on the widget and pointing towards him. When we investigated the footage closely, we saw as Mike got closer to the widget to gesture at it, his line of vision got blocked by the trails left behind by the widget. Additionally, due to identical looking avatars, it wasn't immediately clear who controlled which handle. Given these constraints, Mike didn't opt for simply giving cardinal directions; instead, he distributed the spatial reference across himself and the widget to guide his teammates. He elaborated on this communication challenge:

Mike: I think what would be an addition as far as helping communication is maybe if we had negative symbols. So, you could say, hey blue, go positive this much or this much.
Nigel: Just north, south, east, west.
Mike: Some sort of indication of direction.
Nigel: You could put a compass on the floor in the middle of like, hey this needs to go north.
Mike: If you just had plus minus, you have a center as origin, and you could say, "Hey, go positive, go negative."

The need for negative/positive direction labels in the coordinate system wasn't just a request from the teachers, it emphasized how traditional math diagrams come with default viewing angles (head-on, isometric view). This isn't obvious to the viewer but it shapes how we perceive the diagram. In our design we didn't anticipate this issue as diagrams of 2D coordinate systems don't label negative/positive directions explicitly. It is implicitly understood that up/right is the positive direction while down/left is the negative direction in a 2D coordinate system. But in *TriO*, one can move *around* the diagram, essentially flipping the orientation of positive and negative continuously. This shows that the semiotics of classroom diagrams are often taken for granted. A gentle change in dimensionality and perspective challenged what we might confidently know about coordinate systems.

Challenge of Simultaneous Coordination

In another exercise, teachers were prompted to coordinate drawing a helix around a rod, but technical difficulties didn't allow the widget to move smoothly. That's when Nigel suggested that they should try to draw a basketball hoop. To our surprise, this self-defined goal turned out to be very successful as three teachers coordinated to draw a basketball hoop without any visual reference. Their coordination was mediated by simple phrases such as "now we need to draw the backboard" and "we need a circle here." This moment underlined that joint action doesn't need explicit instructions to be successful. The teachers' coordination emerged from the shared idea of a basketball hoop and the artifact's support for joint, coordinated drawing in 3D space. This marked a clear instance of cognition distributed across the players and the artifact.

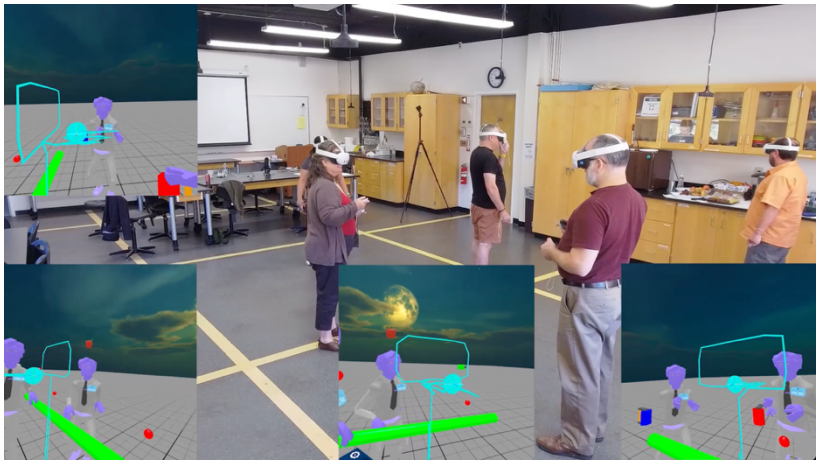

Figure 4: The Completed Basketball Hoop with a Backboard

Closing Remarks and Future Direction

What makes *TriO* a unique math tool is that the artifact is embodied, social, and distributed across subjects. Mathematical activity unfolds through coordinated movement, gesture, language, and perception. The space itself becomes a shared medium for reasoning. As participants engage with TriO, they develop sensorimotor schemes for orienting, aligning, and transforming within 3D space, alongside linguistic schemes for naming, describing, and negotiating spatial relationships. Meaning emerges through this dynamic interplay between action and discourse.

In many classroom settings, geometry remains confined to static diagrams and predominantly two-dimensional representations. Opportunities to reason within fully three-dimensional coordinate systems are comparatively rare. *TriO* addresses this curricular gap by offering a task that is accessible in its basic premise yet intellectually demanding in its mastery. The simplicity of the goal invites participation from all backgrounds, while the depth of spatial coordination required sustains inquiry and growth.

We see strong potential for *TriO* in K-12 education as a tool for cultivating spatial reasoning, embodied coordination, and precise spatial language. Beyond learning specific geometric content, students can have opportunities to experience mathematics as collaborative, enacted, and lived in space.

LINGUISTIC PLASTICITY IN SPATIAL LEARNING ENVIRONMENTS

Camden Bock

camden.bock@maine.edu

Justin Dimmel
The University of Maine
justin.dimmel@maine.edu

Spatial and immersive technologies promise embodied connections between abstract mathematical entities and physical experience, yet interdisciplinary synthesis struggles due to terminological plasticity and hardware-centered descriptions. This systematic review uses a dual-layer coding scheme to index relevant articles from the ERIC database, identifying affordances studied masked by vague labels like "Immersive Virtual Reality" (IVR). Grounded in inclusive materialism, we argue that the failure to precisely index these digital architectures limits our ability to theorize the intra-actions of learners and digitally rendered realizations of mathematical objects.

Keywords: Technology, Mathematical Representations

Spatial and immersive digital technologies have promised embodied connections between abstract mathematical entities and our physical presence in the world. However, across educational research, the theoretical affordances of these technologies are inconsistently described in relation to their use in empirical studies of learning environment design across disciplines. This disconnect creates a barrier for researchers to compare and synthesize research with a broader educational research community.

Conventions in Spatial Display Nomenclature

The terminology for describing digitally rendered spatial environments is varied and plastic, with common references to underlying software and hardware technologies (i.e., Immersive Virtual Reality, Stereoscopic Virtual Reality, Spatial Computing, Augmented Reality, Mixed Reality, and Extended Reality). These catch-all terms mask fundamental differences in the affordances that are supported by different hardware and software technologies, the affordances that are included in a designed learning environment, and the ways in which these affordances might support learner agency over the digitally rendered environment. These terminologies also prioritize the reporting of the brand (Meta Quest, Apple iPad) or a generic term for the underlying technology (stereoscopic head-mounted display, tablet) over the specific spatial properties (e.g., scale, multimodal rendering, spatial navigation) of the "intra-actions" (de Freitas & Sinclair, 2014) that link the embodied use of a digital environment to mathematical meaning making.

The alignment with device marketing terminology serves as a challenge for the PMENA community to interface with researchers in other disciplines with shared interests in technology and learning environment design. In this brief report, we look across educational research disciplines, from medicine to vocational training, and ask how are these spatial properties of intra-actions with spatially realized digital environments reported in relation to teaching and learning?

Systematic Literature Review Method

To understand how affordances are described and studied across a broader set of educational literature, we conducted a systematic literature review following the PRISMA 2020 framework (Page et al., 2021). We identified 5,517 items in the ERIC database, which has an English

language bias but substantially reduces the amount of literature without relevance to teaching and learning captured by our query. Our query was broad in scope, searching for title and abstract matches for commonly used language to describe spatial rendering technologies.

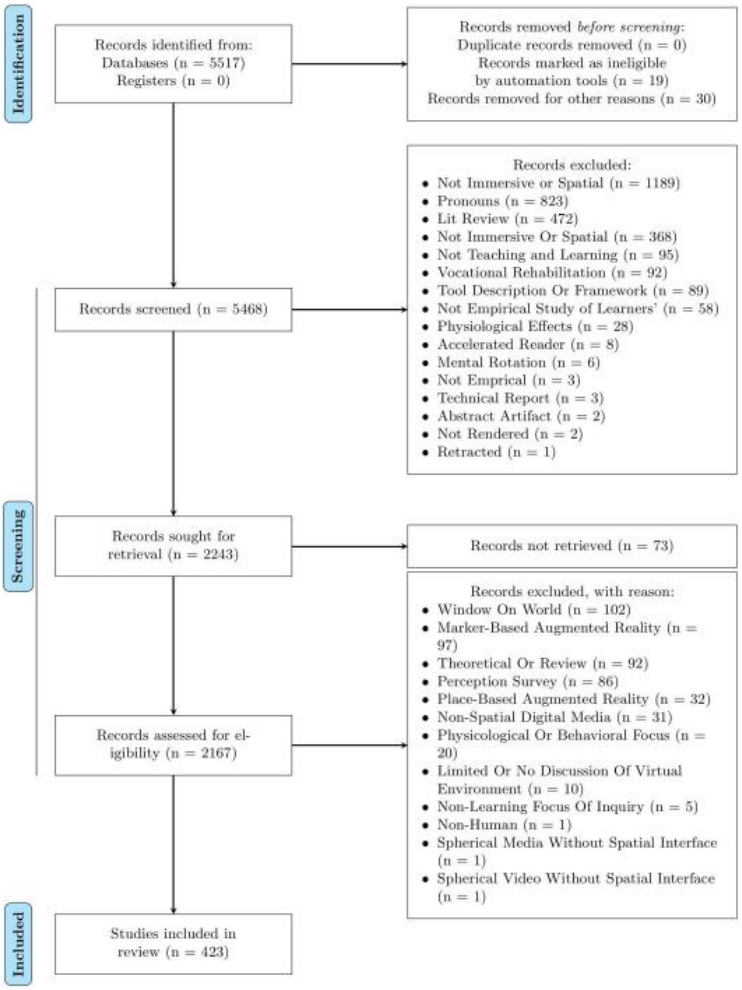

Figure 1: PRISMA Flow Diagram

Selection Process

We conducted an abstract review using ASReview (van de Schoot et al., 2021), where records are sorted in order of projected relevance every record's inclusion or exclusion decision is made by the human reviewer. At this stage, many records were excluded for use of initialisms or abbreviations for other meanings (e.g., "Mental Rotation," or "Mr.") or use of digital technologies without a spatial interface (e.g., descriptions of fixed window-on-world environments similar to *SecondLife* as "immersive virtual reality"). We focused our search to identify digital environments with spatial renderings or spatially embodied interfaces where *learners* could see, feel, or hear properties of the content that they were interacting with through time and space. Many items passed the abstract review phase for further full text screening due to limited descriptions that describe an intervention only in terms of ambiguous terms for the class of technology (e.g., the effects of Augmented Reality on learning).

We were able to retrieve 2243 records for full text eligibility analysis in Catchii (Halman and Oshlack, 2024), without any machine learning automation. For this preliminary analysis, 900 texts were randomly selected for eligibility analysis. We identified 423 records with some spatial element to either the realization of digital objects through either rendering or user interface technologies. Most records are excluded at this phase for using (1) a fixed window-on-world configuration with only two-dimensional rendering and interface, (2) target-based (often marker-based) augmented reality without a described a spatial component to the learner's interactions, and (3) placed-based augmented reality implementations that use GPS (or other spatial positioning) to trigger non-spatial digital media. Only 10 records did not have a detailed enough description of the designed environment to determine if there was a spatial component to their implementation. Some included records had limited descriptions but included figures of participants' use of the environment, or reference commercial or open-source software that documented spatial capacities, or reference other studies of the same designed environment with more thorough descriptions of the spatial capacities.

Coding Schema: Design Reporting and Spatial Affordances

The eligible reports were coded to identify broad trends in patterns of the affordances and learning-related constructs studied across disciplines. Additional descriptive codes were included capture how the authors represented their designed environment.

To contextualize each report, metadata about the publication date, sub-discipline, content area, population, methodology, and leaning-related constructs or outcomes were captured. Additional data was extracted from authors descriptions, or inferred from figures or references for the visual, auditory or haptic renderings system (e.g., Binocular Stereoscopic Displays). These were further described in terms of the Degrees of Freedom (DOF) of supported by the interface; we only considered 3DOF environments supporting rotational movement of the learner or 6DOF environments supporting both rotational and translational movements of the learner. This data supports additional temporal and cross-sub-discipline quantitative analysis, that will be conducted in a future stage of the project.

We captured the level of agency that students had over the representation, from a passive video viewing experience to collaborative interactions with digital objects. We also captured the types of interaction, from taking different perspectives, to manipulation of objects, to creation of new digital objects (Roussou et al., 2006). Finally, we captured the analytical granularity of the designed environments' use in the report's method, to distinguish studies treating the designed environment as a "black box" from studies identifying or isolating specific affordances.

Often information included in these codes was not directly stated in the reports but was inferred from the hardware used or elements of the design of the environment. We captured the language that the researchers used to describe the type of digital technology that they used for their designed environment. We also coded for the presence of a detailed qualitative description of the designed environment, references to a commercially marketed digital environment, the availability of source code, the inclusion of images or videos of the designed environment, or the inclusion of an a priori analysis of the environment.

A secondary round of meta-codes applies the 4E cognitive science framework (Anderson, 2025) to each record's representation of the learning environment as embodied, embedded, extended, and/or enacted, through their theoretical framing, methodology, results, and discussion. The 4E cognitive science framework provides a bridge between a diverse set of theories and disciplinary focus areas to strong strands of research into enactivism, new materialism and embodied cognition in the PMENA community. The 4E lens supports this

bridge with a focus on how processes of learning and knowing are studied, rather than passing trends in consumer hardware, emerging and disappearing software platforms, or disciplinary silos.

Future Analysis: Temporal and Disciplinary Trends

In the next stage of this analysis, we will conduct a temporal analysis of trends across modalities of digital-spatial renderings and the presence of descriptions of the affordances of the reported digital environments. A Bayesian changepoint analysis will be conducted using RBeast (Zhao et al., 2019; McNeill, 2022) and c2z (Skaar, 2023). The Bayesian changepoint analysis is expected to identify changes in research activity around availability of consumer hardware for underlying technologies. We are interested to identify any temporal changes in the specific affordances studied or the use of the underlying technology as a methodological black box.

We will also conduct a cross-discipline analysis to better how to study of the affordances of digital-spatial rendering technologies are distributed across educational research. This will identify affordances relevant to the teaching and learning of mathematics that may have been understudied in the mathematics education literature due to differences in linguistic conventions across disciplines.

Preliminary Findings: Linguistic Ambiguity

Many keywords used to identify literature relevant to spatial, digitally rendered spatial arguments. For example, "Immersive Virtual Reality" presents often throughout this dataset. These environments typically are rendered in a way that includes digital objects but not stimuli from the surrounding physical world, an affordance shared by most implementations of virtual reality. The immersiveness points to a sense of presence, but the implementation can vary widely. NeoTrie (Rodriguez et al., 2021) is a dynamic geometry-like environment in a virtual spatial environment rendered with consumer-grade stereoscopically rendered environment that uses 6DOF tracking for both rendering and embodied interactions with mathematical manipulatives. Other dynamic geometry environments with similar spatial affordances and lack of access to stimuli from physical surroundings may use the word immersive as a qualitative descriptor but not use IVR as a keyword (Walkington et al., 2025).

Astatke (2024) contrasts an implementation of immersive virtual reality as a 3DOF stereoscopic rendering of 360 video with "DVR" (Desktop Virtual Reality) using a monitor, mouse and keyboard to display and navigate a 360 video, in the context of "STREAM-learning." However, the same monitor, mouse and keyboard interface is often described as immersive virtual reality in literature excluded from our analysis during the full-text eligibility phase. These ambiguities were not recently developed. Slater (2003) cautions against confusing immersion and presence in understanding the relationships between affordances of digital environments.

We find similarly ambiguous language across variants of augmented reality, mixed reality, extended reality and other spatial rendering modalities. However, salient affordances cross-cut these technologies. The type of spatial presence and embodied spatial manipulation possible in NeoTrie may be better related to a shAR dynamic geometry implementation (Walkington et al., 2021), though it may be difficult to differentiate in a simple query with a substantially different set of digital-spatial interface affordances available in the tablet-based GeoGebra AR (Gustei et al., 2025).

This study examines preservice mathematics teachers' learning as they engaged in dynamic geometry tasks and structured analysis of students' interactions within dynamic geometry environments (DGEs). Drawing on professional noticing, TPACK, and the Technology-Based Geometric Thinking Framework, the study explored how PSTs interpreted students' geometric thinking and how their reflections reflected TPACK subdomains. Data included written reflections, analyses of students' DGE activity, and pre/post surveys. Findings suggest PSTs increasingly framed DGEs as environments for exploring relationships and invariants. Noticing students' DGE activity emerged as a mechanism for supporting PSTs' TPACK development.

Keywords: Preservice Teacher Education, Teacher Noticing, Technology

Introduction

Technology is an essential part of a student's educational experience, especially in mathematics classrooms where it can deepen conceptual understanding, facilitate visualization, and provide multiple entry points to a task. However, we know that the use of technology alone will not improve learning. Rather, the decisions teachers make about how to use technology determine whether it positively impacts student learning. It is expected that "Well-prepared beginning teachers of mathematics are proficient with tools and technology designed to support mathematical reasoning and sense-making, both in doing mathematics themselves and in supporting student learning of mathematics" (Association of Mathematics Teacher Educators, 2017). Research on technological pedagogical content knowledge (TPACK) has documented growth in preservice teachers' knowledge through coursework and interventions (Mishra & Koehler, 2006; Niess, 2005; Harvey & Caro, 2017) as well as the importance of professional noticing in learning to attend to and interpret students' mathematical thinking (Jacobs et al., 2010). However, these areas remain largely disconnected. In particular, preservice teachers (PSTs) are rarely supported in learning to notice students' thinking as it emerges through interactions with digital tools (Dick et al., 2021; McCulloch et al., 2021).

While many researchers have documented growth in PSTs' TPACK through instructional interventions (e.g., Harvey & Caro, 2017), helping future teachers notice and interpret students' mathematical thinking when technology is involved has not been a central focus in teacher preparation programs (McCulloch et al., 2021). Although learning to notice students' thinking is widely recognized as an essential skill for teaching (Jacobs et al., 2010), relatively little research has examined how PSTs develop this skill within technology-mediated environments (Dick et al., 2021). This gap is particularly important in dynamic geometry environments (DGEs), which offer opportunities for making students' geometric reasoning visible by examining their tool interactions (Arzarello et al., 1998).

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Dynamic geometry environments (DGEs) function not only as tools for constructing mathematical representations but also as mediational spaces where students' geometric thinking becomes visible through their actions, representations, and problem-solving strategies (Arzarello et al., 1998; Dick et al., 2021). Students' dragging, measuring, constructing, conjecturing, exploring, and testing within DGEs can reveal their reasoning about geometric relationships, invariance, and structure (Hoyes et al., 2025). Supporting PSTs in learning to attend to these actions is central to developing their capacity to interpret students' geometric thinking in DGE contexts.

The purpose of this study is to examine how engaging PSTs in dynamic geometry tasks as both learners and emerging teachers, within an instructional sequence intentionally focused on noticing students' thinking, supports the development of TPACK. Specifically, this study investigates how opportunities to analyze students' interactions with DGEs influence PSTs' conceptions of the role of technology in teaching and their reasoning about instructional decision-making. This study is guided by the following research questions:

- RQ1. How and to what aspects of students' geometric thinking do PSTs attend when analyzing video of students interacting with DGEs?
- RQ2. How does engaging in analysis of students' actions with a DGE activity shape PSTs' reasoning about teaching and learning geometry?
- RQ3. How do PSTs conceptualize the role of DGEs in supporting students' geometric thinking?
- RQ4. In what ways do PSTs' reflections and survey responses reflect TPACK subdomains following participation in the instructional sequence?

Theoretical Frameworks

This study draws on technological pedagogical content knowledge (TPACK), professional noticing, and the Technology-Based Geometric Thinking (TBGT) Framework (Hoyes et al., 2025) as complementary perspectives for understanding how PSTs learn to interpret students' geometric thinking in DGEs. TPACK provides a framework for understanding the integrated knowledge required to teach mathematics with technology, emphasizing the interplay among technological, pedagogical, and content knowledge domains (Mishra & Koehler, 2006). Professional noticing describes how teachers learn to attend to, interpret, and respond to students' mathematical thinking (Jacobs, Lamb, & Philipp, 2010). In this study, these perspectives are brought together to examine how PSTs' reasoning develops as they analyze students' actions and geometric thinking in DGEs.

To support PSTs' engagement and potential growth, the instructional sequence incorporated the TBGT Framework, which was designed to guide PSTs' attention to key aspects of students' engagement and geometric thinking in the DGE activity. The framework directed PSTs to consider students' interactions with the DGE, their verbal and written explanations, and the mathematical ideas reflected in those interactions. In this way, the TBGT Framework positioned noticing as an interpretive practice grounded in examining students' actions within DGEs rather than evaluating correctness or task completion.

Within this study, the TBGT Framework supported PSTs in learning what to attend to when analyzing students' interactions with DGEs and what those interactions might reveal about students' geometric reasoning. The TBGT framework-oriented PSTs toward interpreting students' actions and explanations rather than focusing on correctness or task completion. In

doing so, it created opportunities for PSTs to consider how technology, pedagogy, and mathematical content intersect when making sense of students' thinking.

Methods

This study was conducted within a geometry unit of a technology course for secondary PSTs; fifteen PSTs from that course agreed to participate in the study. The course instructor designed an instructional sequence aimed at supporting PSTs' engagement with DGEs and their analysis of students' geometric thinking. During the sequence, PSTs first worked through geometry tasks using DGEs as learners. The TBGT Framework was introduced to support PSTs in attending to students' interactions with the DGE, their written and spoken work, and the mathematical ideas reflected in those interactions. They then analyzed video recordings of secondary students engaging with the same tasks. Through these experiences, PSTs engaged in the practice of noticing students' thinking in technology-mediated environments.

PSTs also completed a pre- and post-TPACK survey (Zelkowski et al., 2013) and written reflections about their work on the DGE tasks, experiences analyzing students' thinking, and developing perspectives on teaching with technology. Quantitative survey data were analyzed using paired samples *t*-tests to examine patterns of change in PSTs' self-reported TPACK. All 15 PSTs completed the pre-survey, and only eight completed all questions in the post-survey. Paired analyses were conducted on matched responses ($n = 8$). Given the small sample size and attrition, results are interpreted descriptively and in relation to qualitative findings.

Qualitative data were analyzed in two complementary ways. First, responses were examined to identify how and to what aspects of students' geometric thinking PSTs attended when analyzing video of students interacting with DGEs. Second, PST reflections were categorized using subdomains of the TPACK framework (Mishra & Koehler, 2006), including technological knowledge (TK), pedagogical knowledge (PK), content knowledge (CK), and their intersections (e.g., TPK, TCK, PCK, and TPACK). Coding was iterative and focused on identifying patterns across PST responses rather than individual trajectories. This analytic approach allowed for examination of both the substance of PSTs' noticing and how their reasoning reflected integrated technological, pedagogical, and content considerations.

Findings

Analysis of PSTs' reflections and survey responses revealed meaningful shifts in how they understood and used DGEs. Three themes emerged that illustrate these shifts: changes in how PSTs conceptualized the role of DGEs, growth in what they noticed about students' geometric thinking, and increasingly integrated instructional reasoning grounded in students' interactions with technology.

Theme 1: From Construction Tool to Reasoning Environment

Initial responses in reflections positioned DGEs as tools for visualization, efficiency, and checking constructions. Over time, some PSTs described dynamic manipulation (especially dragging) as a way to surface invariants, test conjectures, and generalize relationships. In these moments, DGEs were framed less as instruments for producing accurate figures and more as environments that make geometric reasoning visible and support sense-making.

Theme 2: Shifts in What PSTs Notice About Students' Geometric Thinking in DGEs

As PSTs analyzed students' work with DGEs, their attention moved beyond correctness toward how students reasoned through interactions with the tool. PSTs referenced students' strategies (e.g., testing cases through dragging), emerging conjectures, and limitations (e.g., reliance on visual evidence without justification). These descriptions reflect increasingly

differentiated noticing of mathematical properties, invariants, and relationships, as well as attention to students' approaches and misunderstandings.

Theme 3: Instructional Reasoning Informed by DGE Task and Activities

PSTs began to connect what became visible in students' DGE interactions to instructional decisions, including when to press for justification, how to scaffold vocabulary, and how to design tasks that invite comparison and generalization. Reflections increasingly integrated technological, pedagogical, and content considerations. For example, PSTs began using actions in DGEs to reveal structure while planning questions that move students from visual confirmation toward geometric explanation.

Taken together, these themes suggest that when PSTs attended to students' actions within DGEs, they were more likely to conceptualize technology as supporting sense-making and to articulate instructional moves grounded in students' technology-mediated reasoning. This interplay was reflected in language consistent with TCK (technology revealing mathematical structure), TPK (technology shaping instructional choices), and, at times, integrated TPACK.

Conclusions

Preliminary findings suggest that PSTs' shifts in how they conceptualized DGEs, what they noticed about students' geometric thinking, and how they reasoned about instruction were interconnected and reflected movement across TPACK subdomains. When PSTs described DGEs as environments that reveal geometric relationships and invariants rather than tools for producing constructions, their reasoning reflected technological content knowledge (TCK), positioning technology as a means for making mathematical structure visible. As PSTs attended more closely to students' strategies, conjectures, and misunderstandings while interacting with DGEs, their reflections increasingly reflected pedagogical content knowledge (PCK) and technological pedagogical knowledge (TPK), particularly in anticipating student difficulties and considering how technology might shape instructional moves. Moments in which PSTs connected students' DGE activity to specific teaching decisions (e.g., when to press for justification, how to scaffold explanations, or how to leverage dynamic representations to support generalization) demonstrated more integrated technological pedagogical content knowledge (TPACK). In these cases, noticing students' thinking within DGEs functioned as a "bridge" linking mathematical reasoning, instructional decision-making, and technology use.

At the same time, variability in PST responses indicates that integration across subdomains was uneven. Some reflections remained focused on efficiency and visualization, suggesting continued emphasis on technological knowledge (TK) without sustained connections to pedagogy or content. These differences highlight the importance of teacher preparation experiences that explicitly position DGEs as resources for interpreting student thinking and for informing instructional decisions, not solely for constructing or visualizing mathematical ideas. Altogether, these findings suggest that structured opportunities to analyze students' actions in DGEs may support PST movement from isolated TK or TCK perspectives toward more integrated TPACK reasoning, particularly when noticing is foregrounded as a central practice in learning to teach with technology.

This study explores the design and implementation of customized artificial intelligence assistants, developed through ChatGPT, to support mathematics competition problem solving among high school students. The study examines student–assistant interactions by conceptualizing these assistants as mediating artifacts grounded in a problem-solving perspective. Analytical episodes illustrate how the assistants can foster exploration, strategic reformulation, and mathematical argumentation during the resolution of non-routine problems. Preliminary findings suggest that customized AI assistants may contribute to students' development of mathematical knowledge when they are intentionally designed and integrated into cognitively demanding mathematical activities. Implications for the design of AI-supported learning environments in mathematics education are discussed.

Keywords: Problem-Solving, Technology, High School Education

Introduction

Within mathematics education, non-routine problem solving has long been recognized as a central means for promoting the development of mathematical knowledge, particularly in contexts characterized by high cognitive demand, such as mathematics competitions. At the same time, recent advances in generative artificial intelligence (AI) have introduced new opportunities for supporting students' mathematical activity and learning processes (Mishra et al., 2023). However, important questions remain regarding how these technologies can be incorporated into educational settings without replacing students' reasoning processes or diminishing their opportunities to construct mathematical understanding.

This study is situated at the intersection of problem solving and digital technologies. Specifically, it investigates the potential of customized AI assistants developed through ChatGPT as mediators of mathematical learning (Santos-Trigo, 2007). The focus is placed on high school students engaged in the resolution of non-routine mathematics competition problems, a context that remains relatively underexplored within the emerging literature on artificial intelligence in mathematics education.

Purpose and Research Questions

The purpose of this study is to design, refine, and investigate the use of a customized assistant developed in ChatGPT to support mathematics competition problem solving among high school students. The study pursues two complementary goals: (a) generating knowledge about how such assistants can be configured to promote cognitive actions associated with mathematical problem solving (Santos-Trigo, 2007), and (b) producing empirical evidence regarding the problem-solving processes that emerge when students interact with the assistant while working on non-routine mathematical tasks.

The study is guided by the following research questions: (1) How does the use of a customized assistant influence students' processes of exploration, representation, argumentation,

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

and validation while solving mathematics competition problems? (2) What patterns of interaction emerge between students and the assistant during problem-solving processes, particularly regarding the coordination of representations, the use of invariants, generalization, and metacognitive control? (3) What design principles and interaction rules emerge that support students' autonomy, and how are these principles refined through successive cycles of design and implementation?

Conceptual Framework

In this study, problem solving is conceptualized as a knowledge-generating activity through which students explore mathematical situations, formulate conjectures, validate results, and reflect on their strategies (Santos-Trigo, 2007). From this perspective, the emphasis is not limited to obtaining a correct solution; rather, attention is directed toward the cognitive and metacognitive processes that emerge throughout mathematical activity.

Previous research has highlighted the role of non-routine problems as privileged contexts for examining how students construct and reorganize mathematical knowledge, as well as how they make and revise strategic decisions during problem-solving processes (Santos-Trigo & Barrera-Mora, 2007).

Non-Routine Problem Solving and Cognitive Demand

Within the framework of this study, a non-routine problem is understood as a task whose solution cannot be obtained through the direct and mechanical application of a previously learned algorithm. Instead, such problems require students to engage in exploration, conjecture generation, strategic decision-making, and metacognitive monitoring. Because of these characteristics, non-routine problems constitute a central component of mathematics competitions, where exploration, argumentation, and justification are valued more highly than the mere production of answers.

The problems selected for the design and refinement of the assistant were chosen precisely because they provide opportunities to investigate problem solving as a complex mathematical practice. In these contexts, mathematical knowledge develops through the coordination of representations, the production and refinement of conjectures, the construction of arguments, and the communication and revision of results (Santos-Trigo, 2007).

Scaffolding, Agency, and Validation Control in AI-Supported Problem Solving

A major challenge associated with the integration of generative artificial intelligence into mathematics education is preserving students' agency and their capacity to construct mathematical knowledge (Mishra et al., 2023). When AI systems provide plausible explanations or detailed solution procedures, there is a risk that mathematical activity may shift from knowledge construction toward answer seeking or uncritical acceptance of generated responses.

For this reason, the present study focuses on designing the assistant as a form of conversational scaffolding that makes mathematical decisions and justifications visible while avoiding the replacement of students' intellectual work (Zhou et al., 2025). Operationally, the assistant privileges questioning, requests for explanation, and prompts for verification while restricting the provision of complete solutions.

Digital Technologies as Mediating Tools

Digital technologies can function as cognitive tools when they are intentionally designed and integrated into mathematical activity. Beyond automating procedures, such technologies can support exploration, visualization, experimentation, and reflection, thereby expanding opportunities for mathematical inquiry (Santos-Trigo, 2007a). From this perspective, assistants based on generative artificial intelligence—particularly ChatGPT—represent a new class of

digital instruments whose educational value depends critically on both their design and the theoretical principles that guide their use (Haçat & Kepceoğlu, 2025).

Their role is not predetermined by the technology itself; rather, it emerges from the interactions established between students, tasks, and the assistant. In this study, customized AI assistants are conceptualized as mediators of mathematical reasoning.

Research Design

The study adopts a Design-Based Research (DBR) approach focused on the development and refinement of a customized assistant implemented through ChatGPT. Design-Based Research is particularly appropriate for examining the integration of emerging technologies into mathematics education because it supports iterative cycles of design, implementation, analysis, and refinement (Santos-Trigo et al., 2016).

Design Cycles and Design Conjectures

The study is organized around three iterative design cycles. During each cycle: (a) non-routine mathematical problems with the potential to generate multiple solution strategies are selected, (b) students interact with the customized assistant while solving the tasks, (c) interaction data are collected and analyzed, and (d) both the assistant and the tasks are refined based on empirical findings.

This iterative logic is central to design experiments, where the objective extends beyond determining whether an intervention is effective. Instead, the emphasis is placed on understanding how learning processes unfold, when particular forms of support become productive, and under what conditions the intervention may be transferable to other contexts (Cobb et al., 2003). The study is conducted within a mathematics competition preparation environment, where students engage with non-routine problems in sessions that provide sufficient time for exploring strategies, constructing arguments, and discussing alternative approaches.

Task Selection and a Priori Analysis

The mathematical tasks are selected through an a priori analysis that considers four complementary dimensions: (a) the central mathematical ideas involved and their possible curricular connections; (b) potential solution pathways and alternative approaches; (c) anticipated obstacles and difficulties that students may encounter; and (d) opportunities for promoting exploration, representation, argumentation, and validation.

This criterion is important because it reduces the likelihood that interactions with the assistant become limited to the reproduction of procedural steps. Each design cycle generates two complementary forms of outcomes. The first concerns learning and process outcomes, including changes in students' strategies, argumentation practices, and metacognitive control. The second concerns design outcomes, including principles, interaction rules, and specific assistant configurations that prove productive or problematic during implementation.

Context and Participants

The study is conducted with high school students who participate in mathematics competition preparation activities. Participants work in guided problem-solving sessions in which they engage with non-routine mathematical tasks supported by a customized assistant based on generative artificial intelligence.

Desing of the Customized Assistant

The assistant was designed based on principles derived from problem-solving research. Its interventions prioritize recurring conversational actions such as asking students to explain their interpretation of a problem statement, encouraging the construction of representations, prompting

conjecture generation and justification, proposing verification strategies, and inviting students to consider alternative approaches. When students directly request a solution, the assistant redirects the interaction toward graduated hints and reflective questions rather than providing complete answers (Zhou et al., 2025).

The assistant functions as a personalized tutor guided by the following principles: (a) guide rather than solve; (b) follow Pólya's four phases of problem solving; (c) avoid advancing without evidence of understanding; (d) treat errors as opportunities for reflection and learning; and (d) provide support during moments of impasse through minimal and strategically targeted hints.

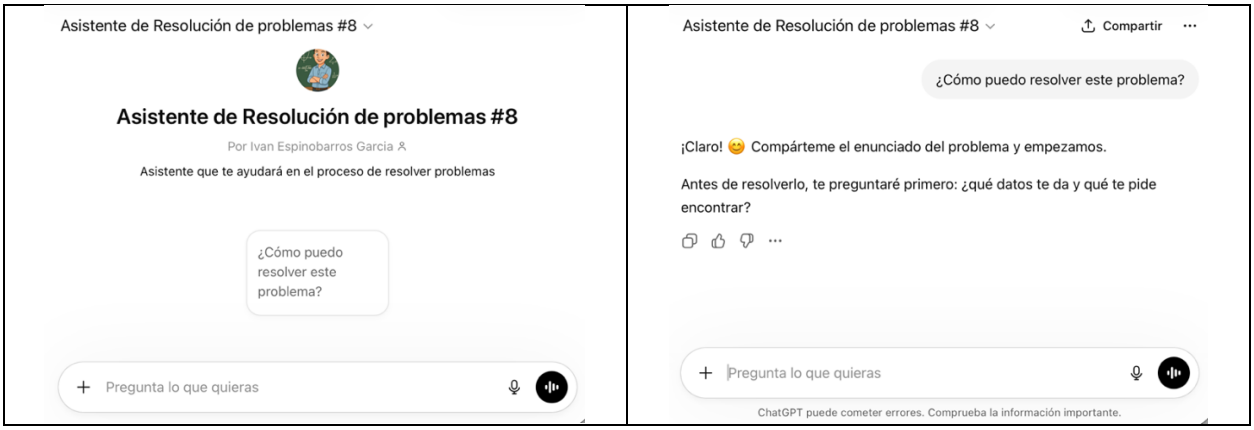

Figure 1: Assistant Interface and Example of an Initial Interaction

Data Collection and Analysis

The data sources include records of student–assistant interactions, students' written productions, and researcher observations. The analysis focuses on: (a) the problem-solving strategies employed by students, (b) the ways in which the assistant functions as cognitive support, (c) changes in students' approaches to solving problems, and (d) evidence of mathematical argumentation and metacognitive control.

Data Sources and Documentation Procedures

Three complementary sources of data are documented throughout the study: (a) complete conversation records between students and the assistant, including questions, responses, and reformulations; (b) students' mathematical productions, such as drafts, sketches, notes, and written justifications; and (c) field notes describing moments of impasse, strategy shifts, and collective discussions when these occur.

Analytic Strategy and Quality Criteria

The analysis combines episodic readings of critical moments with the coding of problem-solving actions and assistant interventions. Initial categories are derived from both the theoretical framework and the a priori analysis of tasks. These categories include: problem interpretation, case exploration, conjecture construction, justification and validation, and metacognitive control.

Preliminary Findings

The analysis of interaction episodes suggests that students tend to use the assistant primarily as a resource for reorganizing their thinking rather than as a source of immediate answers. Several episodes reveal that the assistant's interventions support the reformulation of conjectures, the exploration of alternative representations, and the explicit articulation of

mathematical reasoning. Over time, however, students appeared to adjust their expectations and increasingly recognized the assistant as a mediator of reasoning rather than a problem solver.

Analytical Interaction Vignettes

To illustrate how the assistant functions as a mediator of mathematical activity, a representative interaction episode is presented. The problem analyzed corresponds to Problem 43 from the booklet Introductory Problems for the 35th Mexican Mathematical Olympiad (García Velázquez et al., 2021, p. 25), which states: "Using the numbers from 1 to 26, form 13 fractions such that each number is used exactly once as either a numerator or a denominator. After simplifying all fractions, what is the maximum number of integers that can be obtained?"

The four tables that follow constitute an analytical excerpt that allows the interaction to be interpreted through the lens of Pólya's problem-solving phases. Table 1 illustrates the stage of understanding the problem. During this phase, the assistant directs the student's attention toward two critical constraints: divisibility and the requirement that each number be used exactly once. Rather than providing guidance toward a specific solution, the assistant encourages the student to articulate the conditions embedded in the problem statement.

Table 1: Pólya's First Phase

Student	Problem solving assistant #8
Problema 43. Con los números del 1 al 26 se quieren formar 13 fracciones, usando los números disponibles como numerador o denominador de manera que cada uno de ellos se use solo una vez. Luego, cada fracción se simplifica. ¿Cuál es la máxima cantidad de enteros que se pueden obtener después de la simplificación?	¡Buen problema! 🧩 Antes de pensar en cálculos, vamos con la Fase 1: comprenderlo. Cuéntame con tus propias palabras: ¿Qué números se pueden usar, cuántas fracciones hay que formar y qué significa que "después de simplificar se obtengan enteros"?
Se pueden usar 26 números, del 1 al 26, se pueden formar 13 fracciones pero tal vez no todas cumplen con los requisitos del problema	Bien, ya identificaste los datos principales ✅ Afinemos una parte clave: el problema dice que los números del 1 al 26 se usan como numerador o denominador, y que cada uno se usa solo una vez. Entonces, ¿crees que al final deben usarse los 26 números exactamente una vez para formar las 13 fracciones?

Table 2 corresponds to the design of a plan. The assistant invites the student to identify potentially productive numerical relationships and introduces strategic criteria for constructing fractions that simplify to integers. In this way, the assistant supports the development of a plan while preserving the student's responsibility for making mathematical decisions.

Table 2: Pólya's Second Phase

Student	Problem solving assistant #8
	Ya entendimos el problema, así que pasemos con cuidado a la Fase 2: diseñar un plan. Queremos maximizar la cantidad de fracciones que terminan siendo enteros. Piensa en esto: Si eliges una pareja (a, b) para una fracción, necesitas que uno sea múltiplo del otro. Con los números del 1 al 26, ¿qué números te parecen "fáciles" de emparejar porque tienen muchos múltiplos disponibles? 🤔
Se me ocurren el 6, el 8, el 12, el 16, el 20 y el 24	¡Buena observación! Esos números grandes pueden funcionar muy bien como numeradores, porque varios tienen divisores entre 1 y 26 ✅ Ahora pensemos al revés: si quieres que una fracción sea entera, conviene formar parejas tipo: $\frac{\text{múltiplo}}{\text{divisor}}$

Table 3 reflects the implementation of the plan. The student proposes concrete pairings; the assistant responds by encouraging reflection on the mathematical validity of those choices.

Table 3: Pólya's Third Phase

Student	Problem solving assistant #8
12/4, 16/8, 20/10, 24/6	Ahora piensa estratégicamente 🤔 El problema pide el máximo número posible de fracciones que se simplifican a enteros. Como hay 13 fracciones en total, una pregunta útil es: ¿Crees que es posible lograr que las 13 sean enteros? ¿O habrá algunos números "problemáticos" que obliguen a que alguna fracción no lo sea? Mira especialmente los números primos grandes como $13, 17, 19, 23$. ¿Qué múltiplos tienen dentro del 1 al 26?
Para los números 13, 17, 19, 23; se pueden formar las fracciones 26/13, 19/17, 23/1	Interesante razonamiento 💡 Veo una idea importante ahí, pero quiero que revisemos algo con calma. Propusiste: $\frac{26}{13}, \frac{19}{17}, \frac{23}{1}$ Pregúntate una por una: ¿$26/13$ se convierte en entero? ¿$19/17$ se convierte en entero? ¿$23/1$ se convierte en entero? Y además: ¿en $19/17$, el denominador 17 divide al numerador 19? 🤔

Finally, Table 4 represents the stage of looking back and validating the solution. The assistant prompts the student to verify whether all numbers have been used exactly once and whether the proposed construction satisfies the requirements of the problem. Through these interventions, the assistant encourages error detection, validation, and strategic revision.

Table 4: Pólya's Fourth Phase

Student	Problem solving assistant #8
	Ahora prueba a emparejarlos como "múltiplo / divisor." Mira algunos candidatos: $\frac{14}{7}, \frac{15}{5}, \frac{18}{9}, \frac{21}{3}, \frac{22}{11}$ ¿Qué número quedaría sin pareja con esa elección? ¿Y con qué podrías emparejarlo para formar la sexta fracción?
14/2, 15/3, 25/5, 21/7, 18/9, 22/11	¡Muy bien! 👏 Estás construyendo las parejas con mucha estrategia. Tus nuevas fracciones son: $\frac{14}{2}, \frac{15}{3}, \frac{25}{5}, \frac{21}{7}, \frac{18}{9}, \frac{22}{11}$ Ahora hagamos una revisión cuidadosa (Fase 4 🔍): no quiero avanzar solo por cortesía. ¿Puedes revisar si en todas las fracciones que has construido hasta ahora cada número del 1 al 26 aparece exactamente una vez? Mira especialmente el 2, el 3, el 5 y verifica que ninguno se haya repetido ni que haya quedado alguno sin usar.

For purposes of analytical transparency, the complete interaction can be accessed at: https://chatgpt.com/share/6a16319c-e204-83e8-9b84-662ff1c25e01, the version used during the interaction corresponded to GPT-5.5 (instant).

Discussion

The findings suggest that generative artificial intelligence can function as a mediating tool for mathematical problem solving when its design is oriented toward supporting students' learning processes rather than optimizing answer production. In particular, the interaction episodes illustrate how conversational moves such as requesting conditions, eliciting justifications, and proposing verification strategies can foster mathematical monitoring practices and contribute to the reconstruction of mathematical knowledge during problem solving.

Contributions to Mathematics Education Research

This study contributes to the growing body of research on artificial intelligence in mathematics education by demonstrating how customized AI assistants can be intentionally designed to support mathematical problem solving without diminishing students' intellectual responsibility. Rather than conceptualizing AI systems primarily as providers of explanations or solutions, the study positions customized assistants as mediators of mathematical activity. This perspective shifts attention from the technological capabilities of AI systems to the design principles that shape students' interactions with them.

Limitations and Future Work

As a design-based research study, the findings are necessarily influenced by the context of implementation, the characteristics of the selected tasks, and the interaction rules embedded within the assistant. Consequently, the results should not be interpreted as universally generalizable but rather as contextually grounded design knowledge.

An additional limitation concerns the inherent variability of generative AI models. Because responses may vary across interactions and system updates, continuous monitoring is required to ensure consistency and alignment with educational goals (Abu Daqar et al., 2025).

Future research will expand the range of mathematical problems incorporated into the design cycles and will examine students' interactions over longer periods of time. Particular attention will be devoted to understanding how students internalize practices of verification, argumentation, and strategic reflection beyond their direct interactions with the assistant (García Navarro et al., 2025).

Implications for Practice and Assessment

From a practical perspective, the findings suggest that integrating customized AI assistants into high school mathematics education requires explicit agreements regarding what constitutes mathematical progress and meaningful learning. Rather than focusing exclusively on final answers, assessment practices should attend to students' problem-solving processes, including the quality of their justifications, their capacity to verify mathematical claims, and their strategic flexibility when confronting unfamiliar tasks. One promising avenue for future work involves the development of assessment rubrics centered on problem-solving actions such as exploring, representing, justifying, and validating, as well as examining their coherence with AI-mediated interaction records.

Conclusions

This study highlights the importance of intentionally and theoretically grounded designs for customized assistants based on generative artificial intelligence. Such designs are essential for avoiding purely instrumental uses of AI that reduce students' mathematical activity to the production of immediate answers.

The findings suggest that when AI-based assistants are conceived as mediating instruments aligned with a problem-solving perspective, they can support exploration, the explicit articulation of reasoning, and metacognitive control without displacing students' opportunities to develop mathematical knowledge. From this perspective, artificial intelligence does not function as a substitute for mathematical thinking but rather as a resource that can contribute to its reorganization and enrichment within cognitively demanding environments.

The customized assistant developed in this study incorporates carefully designed interventions that prioritize guiding questions, requests for justification, verification prompts, and representational shifts instead of complete solutions. This design enables students to maintain responsibility for evaluating the validity of their inferences and the coherence of their strategies, thereby supporting the progressive development of mathematical knowledge.

The significance of this tool for mathematics education lies in its potential to expand opportunities for formative feedback within complex mathematical tasks. Unlike traditional resources that provide fixed answers or standardized procedures, the customized assistant enables dynamic interactions that adapt to students' evolving understandings and support reflection in real time. This feature is particularly relevant in educational settings where individualized support is limited but where conceptual depth and rigorous argumentation remain central goals.

Within the specific context of mathematics competitions, the assistant assumes a distinctive role. Rather than functioning as a generator of shortcuts or model solutions, it operates as a mediator that supports strategic exploration, the identification of invariants, the analysis of extreme cases, and the comparison of alternative solution methods. Its purpose is therefore not to accelerate answer production but to strengthen the mathematical practices that characterize successful engagement with non-routine problems.

Ultimately, this work opens an important line of inquiry regarding how artificial intelligence can be integrated into mathematics competition preparation while preserving the formative and

cognitive nature of problem-solving activity. More broadly, it suggests that the educational potential of AI lies not in replacing mathematical thinking, but in creating conditions that encourage students to engage more deeply with it.

HOW CHILDREN USE DIRECTION AND ABSOLUTE VALUE ON NUMBER LINE TASKS: EVIDENCE FROM FIRST AND THIRD GRADERS

Esther Im
Purdue University
ime@purdue.edu

Laura Bofferding
Purdue University
lbofferd@purdue.edu

Children often struggle to coordinate direction, magnitude, and movement simultaneously on integer number line tasks, and language used in prompts may influence their reasoning. We randomly assigned 29 first and 28 third graders to either numbered or unnumbered lines, and they completed five tasks where they indicated movement to go "up/down" or "add/subtract" in a one-on-one interview. We analyzed data statistically and qualitatively through coding responses. Findings only showed a significant difference between first and third graders on numbered lines. Students usually used direction-based reasoning, except for third graders, who shifted to absolute value reasoning when the prompts asked them to "add/subtract." The findings contribute to research on how language may impact children's understanding of directed magnitudes and may inform how they make sense of integer operations.

Keywords: Number Concepts and Operations, Elementary School, Cognition, Mathematical Representations

Although formal instruction on integers in the United States typically begins in middle school, many students continue to struggle with integer operations (Hawthorne et al., 2022; National Governors Association Center for Best Practices & Council of Chief State School Officers [NGA Center & CCSSO], 2010). Evidence shows that young children may already possess meaningful intuitions about direction, magnitude, and movement of integers that transfer from their experiences with whole numbers (Bofferding, 2014; 2019; Hawthorne et al., 2022; Thompson & Dreyfus, 1988; Wessman-Enzinger, 2019). These early intuitions could support earlier integer instruction to better prepare students for operations with integers and help them avoid the rules that expire (Karp et al., 2014) that confuse students when they learn about negative integers long after learning about whole number operations.

Researchers have studied how young children reason about direction, magnitude, and movement of integers on a number line and how they coordinate these concepts from different starting positions on a number line (Bofferding, 2014; Thompson & Dreyfus, 1988; Wessman-Enzinger, 2019). For example, Thompson & Dreyfus (1988) experimented with integer addition and subtraction as directed transformations of integers (e.g., [30–60] means start at 30 and move 60 spaces in the negative direction). Yet Bofferding (2019) suggested that this conception of integers works for addition but not as well for subtraction and offered an alternative interpretation of integers based on language that young students naturally use to signify directed operations. For instance, addition can be interpreted as "getting more" positive or negative and subtraction as "getting less" positive or negative from what one already has (Bofferding, 2019, p. 264). For example, a student might explain that –8 is more negative than –6. In this interpretation, numbers exist on a continuum with "more positive" meaning "less negative" (Bofferding, 2019, p. 264). Extending this perspective, "more negative" would correspond to "less positive." For example, in Bofferding's (2019) work with children in second grade, she found that students could solve a problem like 3 – (–1) = 4 by understanding that subtracting a negative or "getting less negative" meant moving in the positive direction (p. 264).

Additionally, an investigation into how the presence or absence of negative and positive numbers on a number line influences children's coordination of direction, magnitude, and movement on a number remains mostly unexplored. Studying how children reason with or without the presence of integer labels on a number line can illuminate their strategies for integrating negative number concepts into their existing knowledge base.

The present study examines how early elementary students respond to *directed magnitude* language that directs upward or downward movement with a specified magnitude on a vertical number line in contrast to *directed operations* language (e.g., adding or subtracting a specified magnitude). Additionally, it investigates how the presence or absence of positive and negative number labels on a number line either supports or constrains students' performance on these tasks. For clarity, the term *directed magnitude* will be used to refer to movement that considers direction and quantity simultaneously. The term *absolute value reasoning* will refer to strategies that attend only to magnitude, while ignoring or inconsistently incorporating direction.

Research Questions

1. How does the use of directional language (e.g., "up/down") and operational language (e.g., "add/subtract") influence students' responses to vertical number-line tasks?
2. To what extent does the presence or absence of numbers on a number line significantly affect students' movement on the number line?

Theoretical Framework

Case's (1996) Central Conceptual Structures for Number (CCSN) offers a productive framework of whole number development that can be extended to explain how children integrate integer ideas into their conceptual structures (Bofferding, 2014; 2019; Case, 1996). Sometimes referred to as a "mental counting line" or "mental number line," Case (1996) explains that children construct a numerical structure in which moving from one position to the next represents adding or subtracting one unit. Case (1996; Okamoto & Case, 1996) further explains that movement along this mental number line also involves differing magnitudes. These concepts form the basis for integer reasoning, where both direction and magnitude must be coordinated.

Bofferding (2019) suggests that integers can be interpreted as *directed displacements*, *directed magnitudes* or vector-like movements on a number line (p. 263). As seen in Thompson and Dreyfus' (1988) report on a computerized turtle's movement along a number line, two sixth graders initially struggled to distinguish between the starting position of the turtle and its displacement. Drawing on Vergnaud's analysis of conceptual fields, the authors noted that the students interpreted the integer as a static number—the turtle's new location—rather than as a transformation involving direction and magnitude. Thompson and Dreyfus (1988) explain that understanding an integer as displacement required that the students have a multiplicative understanding of magnitude and direction—a structure that students eventually developed.

Most studies have used magnitude-based language (e.g., which number is greater: –5 or –6?); or order-based language (e.g., which number is closer to 0? –1 or –2?) (Bofferding, 2014; 2019; Lamb et al., 2018); yet few studies have looked at the influence of operational language (e.g., add or subtract 2) on students' integer reasoning on a number line. Research also shows that operational signs (e.g., +/–) cue whole number strategies when students solve integer addition and subtraction problems (Aqazade & Bofferding, 2021). It is possible, then, that just as students use whole number strategies when they "see" an addition or subtraction sign, they might do the same when they "hear" instructions to add or subtract. This suggests that operational prompts in number line tasks may lead to whole number reasoning rather than directed magnitude reasoning.

A common strategy in whole number reasoning is treating negative numbers by their absolute values (Aqazade, 2022). For example, in Aqazade's (2022) work with fifth graders' and their interpretation of temperature changes, one student, interpreted a change from –20 to 15 degrees as "more cold," explaining, "Because twenty is like going less and then to fifteen, it got more cold" (p. 166). The student understood that –20 meant it was cold because the temperature was in the negatives, but viewed 15 degrees as being less than –20, which makes sense if they are viewing the numbers from an absolute value perspective. Related to absolute value reasoning is a whole number strategy for adding integers, where students will add the absolute values of the numbers but keep the negative sign in the sum (Aqazade & Bofferding, 2021). For example, –1 + 7 will be added as 1 + 7 = 8, and the final answer will be –8, to acknowledge the negative sign (Aqazade & Bofferding, 2021, p. 88). Termed the "add make negative" strategy, Aqazade and Bofferding (2021) found that students consistently used this strategy when adding integers.

Methods

Participants and Design

This study took place in an elementary school in the Midwest during the first two months of Fall 2019. The participants were 29 first grade students and 28 third grade students. There were 16 male and 13 female students in first grade and 11 male and 17 female students in third grade. No other demographic data was collected.

The data were obtained from one section of a pre-test that students took one-on-one with a researcher during a video-taped interview as part of a larger study. The students were randomly assigned either a test form either with or without numbers on a vertical number line (see Figure 1). Half of the first and third graders were randomly assigned to numbered lines and the other half to unnumbered lines. The five questions were:

1. Show where the ant would end up if it goes down 2. [Ant is at –3]
2. Show where the ant would end up if it goes up 2. [Ant is at –2]
3. Show how the ant moves if it adds 2. [Ant is at –3]
4. Show how the ant moves if it subtracts 2. [Ant is at –2]
5. Show where the ant would end up if it goes up 2 then down 2. [Ant is at 0]

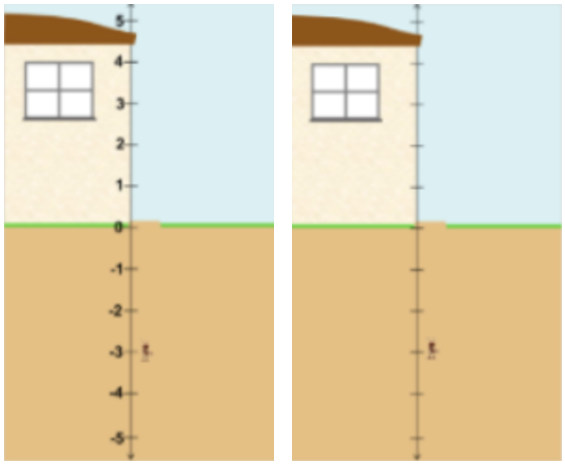

Figure 1: Student Response Forms With (left) and Without Numbers (right)

Data Analysis

First, we analyzed the data quantitatively in two groups using an independent samples t-test: Group A (first and third graders who received numbered lines) and Group B (first and third graders who received unnumbered lines). Neither group passed Levene's test of equal variances; therefore, we used Welch's t-test.

Next, we conducted a qualitative analysis of all 55 student responses to identify patterns in errors and correct responses. We coded based on whether the direction the student moved was correct, the distance moved was correct, or whether they used distance without direction, or direction without distance. Responses in which students primarily used direction were coded as *directed magnitude*, while responses in which students used distance without direction were coded as *absolute value reasoning*. We also created a subcode of *miscount* in cases where students clearly used directed magnitude or absolute value thinking but either counted the initial number in their count or moved their finger too fast when counting, going a tick mark too far. For example, in the former case, if the ant was at –3 and the student was asked to move it down 2, they might count the –3 (the ant's location) as part of the count and move the ant to –4. In the latter case, they might move the ant from –3 to below –5, when trying to count down by 2. Additional patterns also emerged that diverged from the direction and distance categories, and these were grouped under the code *other*. We analyzed errors by number line format (numbered or unnumbered lines), by grade level, and by two separate question groups: 1) questions 1–2 ("down/up") versus questions 3–4 ("add/subtract"), and 2) questions asking, "up vs. add" versus "down vs. subtract." We consulted the relevant video segments to check all responses. The codes used are shown in Table 1.

Table 1: Codes and Descriptions

Codes	Description
	Directed Magnitude
Directed Magnitude (DM)	Uses both direction and magnitude successfully to get the correct answer
DM Miscount	Moves in the correct direction with a slight miscount (i.e., counting the initial number in their count or moving their finger a little too fast and going a tick mark too far).
Direction (Random Amount)	Moves in the correct direction but with a random magnitude (i.e., when the amount moved seems more than a miscount).
	Absolute Value Reasoning
Absolute Value (AV)	Interprets starting number as positive and adds the movement number while ignoring the negative signs; uses magnitudes only.
Absolute Value Miscount	Interprets starting number as positive and adds the given number as a positive but miscounts the final number.
Absolute Value, Random	Interprets starting number as positive, adds the given number as a positive but final response appears random.

Other

Includes: Add as Positive (treating all numbers as positive and adding them for a positive sum), Location (moving to the location of the directed number), Random (did not move in the correct direction or move the correct amount), Didn't Move (kept the ant at its starting location), and Pattern (used the starting location as a repeating pattern to predict the answer).

No response/skip Student did not answer

Results

For numbered lines, third graders outperformed first graders (60% vs. 44% correct) (see Table 2); showing a statistically significant difference, t (22.289) = –2.133, p = .044, d = .801 (large). On unnumbered lines, third graders answered 67% of items correctly in contrast to 55% for first graders; this difference was not statistically significant, t (24.254) = –.691, p = .496, d = –.256 (small).

Overall, third graders answered over 60% of the questions correctly across both number line formats, compared to about 50% of first graders. The predominant response pattern across both grade levels and number line formats was the use of direction, where students moved in the correct direction but not always with the correct distance. For example, when asked where the ant will end up if it goes down two (starting position at –3), one first grader indicated that it would go down to –4. Their response suggests they knew that they were moving down (correct direction) but were not accurate in the distance moved. In contrast, third graders with numbered lines showed more absolute value reasoning particularly on the "add/subtract" questions, where they treated the ant's starting position as a positive number and added the absolute value of the directed number. For example, when one third grader was asked where the ant would end up if it "adds two" (starting position at –3), they settled on –4, adding the absolute value of the ant's starting point (–3) plus the amount it moved (i.e., |–3| + 2), but with a slight miscount.

Table 2: Percent Correct for Questions 1–4

	Numbered Lines		Unnumbered Lines	
	1st	3rd	1st	3rd
Directed Magnitude (DM)	44%	60%	55%	67%
Direction (Random Amount)	35%	25%	33%	53%
DM Miscount	20%	13%	22%	24%
Absolute Value	10%	38%	15%	12%
Absolute Value Miscount	0%	21%	0%	0%
Absolute Value (Random)	0%	0%	11%	12%
Other	31%	0%	4%	0%
No response/Skip	0%	4%	11%	0%

On Questions 1 and 2, across both grade levels and number line formats, directed magnitude responses were the most frequent, ranging from 67–100%. For example, one first grader answering Question 1 (go down two from –3), can be seen in the video looking at –4 with their eyes and telling the interviewer that the answer would be 4 (referring to –4). Thus, the student moved in the correct direction but miscounted the distance. On Question 2, another first grader moved the ant up from –2 to 2, when asked to make it go "up two." The video segment showed

that the student seemed focused more on where it could move ("to" two), rather than a specific amount of movement. A breakdown of scores by question are shown in Table 3.

Table 3: Frequency of Strategies for Questions 1–4

	Numbered		Unnumbered		Numbered		Unnumbered	
	1st	3rd	1st	3rd	1st	3rd	1st	3rd
	Q1 (down)				Q2 (up)			
Directed Magnitude	71%	87%	60%	62%	43%	73%	60%	87%
Direction (Random Amount)	50%	50%	83%	80%	50%	75%	50%	50%
DM Miscount	25%	0%	0%	20%	13%	0%	33%	50%
Absolute Value	0%	0%	0%	0%	0%	0%	17%	0%
Absolute Value Miscount	0%	0%	0%	0%	0%	25%	0%	0%
Other	25%	0%	0%	0%	38%	0%	0%	0%
No Response/Skip	0%	50%	17%	0%	0%	0%	0%	0%
	Q3 (add)				Q4 (subtract)			
Directed Magnitude	43%	40%	47%	39%	43%	40%	53%	85%
Direction (Random Amount)	22%	20%	25%	38%	25%	0%	0%	50%
DM Miscount	11%	10%	25%	25%	38%	22%	29%	0%
Absolute Value	22%	40%	13%	25%	13%	56%	29%	0%
Absolute Value Miscount	0%	10%	0%	0%	0%	22%	0%	0%
Absolute Value (Random)	0%	0%	13%	13%	0%	0%	29%	50%
Other	33%	0%	13%	0%	25%	0%	0%	0%
No Response/Skip	0%	0%	13%	0%	0%	0%	14%	0%

For Questions 3 and 4 (add/subtract), directed magnitude responses were most frequent for first graders on numbered lines (47%) and for third graders on unnumbered lines (60%). For example, on Question 3 (add), one student asked, "Is that up or down?", then chose to go down but returned to it after hearing that the next question was about subtraction and said, "I think this one's up (Question 3) and this one's down (Question 4)." In contrast, absolute value responses were most prominent for third graders on numbered lines (68%); whereas, first graders' responses on unnumbered lines showed a balanced pattern, with direction and absolute value each at 40%. For example, on Question 3 (adding 2 to the ant's position at –3), one third grader chose –5 and said, "Cause if you add 2 to 3, it's 5," treating all the numbers by their absolute values.

For the second analysis, where questions were analyzed by comparing how students did on "up vs. add" and "down vs. subtract," their responses were more varied. On the "up vs. add" questions, all students used direction, except for third graders on numbered lines—they used direction for "up" and absolute value for "down." For both the down and subtract questions, first graders on numbered lines and third graders on unnumbered lines used direction. The unusual finding, however, was when both first graders on unnumbered lines and third graders on numbered lines used direction for "down" and absolute value for "subtract" (see Table 3, Q1 and Q4).

Finally, Question 5 was analyzed separately as it contained two steps: "up two, then down two." The codes that emerged were like the previous codes, where directional responses were

dominant but with a lot more variation, such as a correct response on the first step then moving to the location of the number on the second step (e.g., moves from 0 to 2, then to –2). Students seemed to also demonstrate an understanding of additive inverses, where they would give a single correct response combining both steps (e.g., 0). Another interesting finding was the possible use of zero as a reference point. Several students moved up from zero for the first step and seemed to come back down to zero before moving down for the second step. To add to the interesting conceptions of the number line, one third grader interpreted the middle of the number line as 50 (on his unnumbered line) and said the ant could go either way, such as 90 or 10.

Taken together, students' reasoning reflected a consistent preference for direction, but their absolute value thinking appeared—especially for third graders with numbered lines and for first graders with unnumbered lines—when the prompts used operational language (e.g., add or subtract).

Discussion and Conclusion

A key finding that emerged was the third graders' shift from using direction on the up/down questions to absolute value on the add/subtract questions on numbered lines. This finding suggests that the language of the operational prompt together with the presence of numbers on the number lines may have cued whole number reasoning. Aqazade and Bofferding (2021) noted a similar pattern in fifth graders when presented with integer addition problems. For example, one fifth grader explained that for −9 + 2, adding two meant that he would be staying in the negatives and so he would end up at –11 (Aqazade & Bofferding, 2021). A similar pattern was seen in a fifth grader's explanation (Aqazade, 2022) that a change in temperature from –20 to 15 was a drop in temperature because she viewed it as a change from 20 to 15 degrees, which, in absolute value terms would be a decrease. Students' sensitivity to operational prompts suggests that providing opportunities to practice with operational prompts while supporting their directional reasoning may enhance their thinking with integer operations.

At the same time, for first graders across both number line formats, the results on the add/subtract items in particular suggest that they have an easier time thinking about addition as going up and subtraction as going down on the number line and that they can preference that reasoning over considering the absolute value of the numbers. This suggests that first graders may be ready to incorporate distance with direction using directed magnitude prompts, such as "more high" (moving up) or "less low" (also moving up).

The predominant reasoning types in this study align with prior reports on early understanding of direction and magnitude. Bofferding (2014) identified direction-biased reasoning where students considered the direction separately from magnitude (absolute value) as well as magnitude-aware students who could focus on either direction or magnitude but not at the same time. Thompson and Dreyfus (1988) reported a similar pattern with older students on integer displacement tasks.

The overall responses of first and third graders on unnumbered lines were surprising. Both grade levels shifted from directional reasoning to absolute value reasoning on the "subtract" question, which did not match our expectations, especially for first graders. We expected that first graders on unnumbered lines would default to their sense of direction, rather than absolute value. Further studies on students' reasoning on unnumbered lines with a larger sample size, and a variety of questions and interview prompting may yield clearer results on these groups.

Together, these patterns align with Case's (1996) account of how children coordinate movement, magnitude, and direction for whole number. They also confirm evidence that children treat these concepts separately when integrating negative numbers before they

assimilate them into a cohesive framework (Bofferding, 2014; Thompson & Dreyfus, 1988). Coupled with our findings on how prompting language cues students' directional or absolute value thinking, there may be value in considering how using different types of prompts on number line tasks may prepare students for operations with integers.

BEYOND CORRECTNESS: DESIGNING LARGE LANGUAGE MODELS AS CO-MATHEMATIZERS THROUGH A UNITS-IN-MATHEMATIZING LENS

Boram Lee
Utah State University
boram.lee@usu.edu

Seyedehkhadijeh Azimi
Virginia State University
sazimi@vsu.edu

Current research on Large Language Models (LLMs)-based AI focuses on problem-solving accuracy through adaptive feedback, often neglecting the student's interpretive process of mathematizing. This study proposes the Units-In-Mathematizing (UIM) lens, a framework for designing LLMs as co-mathematizers. While recent AI-related studies emphasize procedural correctness, the UIM lens attends to students' interpretative process of mathematizing by emphasizing what they identify and coordinate in the process. Through an empirical case and a comparative scenario, we demonstrate how UIM-informed LLMs could reveal and support students' mathematizing process. This framework provides a principled foundation for LLM design that prioritizes sense-making over correction on problem-solving.

Keywords: Technology, Modeling, Problem-Solving

Recent advancements in Large Language Models (LLMs)-based AI have prioritized personalized mathematics learning (Barrera et al., 2024; Liu et al., 2025) through real-time, adaptive feedback (e.g., LLM-based chatbots acting as intelligent tutors) (Goel & Ghanta, 2025; Scarlatos et al., 2025). While these approaches improve problem-solving fluency, focusing solely on correct answers risks reducing mathematics to a "closed system" (Freudenthal, 1968, p.7) of rules rather than an open-ended process emphasizing sense-making (Reusser, 1988). This study addresses a critical question for the mathematics education community: *How should LLMs be designed to serve as instructional partners for meaningful mathematics rather than as evaluators of correctness in problem-solving?* To address this, we foreground *mathematizing*—the critical transition from a real model to a mathematical model (Ferri, 2006; English, 2006), as conceptualized in the research body on mathematical modeling. We argue that AI must move beyond error correction to support students' interpretive work in mathematizing situations. Accordingly, we propose the *Units-in-Mathematizing* (UIM) lens as a conceptual and analytic foundation for future LLM-based instructional design. Rather than reporting the development or evaluation of a specific LLM system, this paper develops UIM as a lens for specifying what an LLM-based instructional partner should attend to, infer, and respond to when engaging with students' mathematizing. In the following sections, we define the UIM lens, illustrate its analytic value through empirical student data, and discuss its implications for future LLM-based interactions.

Theoretical Perspective

Units-In-Mathematizing (UIM)

In this section, we bridge studies focusing on *units* and those highlighting *mathematizing*, from which we develop the UIM lens. First, unit and unitizing have been addressed in a substantial body of research related to multiplicative reasoning (Behr et al., 1994; Zwanch & Wilkins, 2021) and fractions (Boyce et al., 2024). These studies illustrate that how students define and identify a unit is critical for their ability to think multiplicatively (e.g., Götze & Baiker, 2021) and to apply fractions flexibly (e.g., Steffe &Olive, 2011). Notably, most mathematical situations examined in this line of research include explicitly given units of one,

such as a single bar (e.g., Hackenberg, 2007; Norton et al., 2015). Consequently, the current literature primarily focuses on the cognitive processes students engage in when forming composite units based on pre-given units of one. These studies show that what students identify and count as *units* plays an important role in students' multiplicative and fractional reasoning.

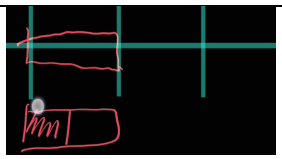
Along a similar line of inquiry, though often without explicitly using the term *unit*, research in mathematical modeling shows that when individuals mathematize situations, they begin by organizing the situation around particular entities and subsequently represent them mathematically (e.g., Chamberlin & Moon, 2005; English, 2006). For instance, Maaß (2006) demonstrates that when a student interprets a problem situation in a distorted way, resulting in an invalid real model (Ferri, 2006), this interpretation inevitably leads to the construction of a distorted mathematical model. This finding underscores the importance of examining how students interpret and structure problem situations and how these interpretations shape their transitions from real models to mathematical models. However, this aspect of students' mathematical activity remains underexplored (Galbraith and Stillman, 2006). As a result, we lack in-depth explanations regarding how students independently form real models, both valid and invalid, in the first place.

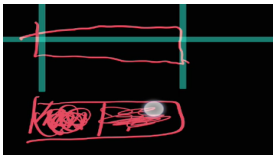
To address this gap, we bridge units with the mathematizing process. We propose the *Units-In-Mathematizing* (UIM) lens, in which we define units as the referents that students take up from situations and coordinate in their mathematizing process. In this lens, units are not limited to mathematically conventional units of one or quantitative units. Rather, they include any referents, whether mathematically relevant or not, that students use as anchors for interpreting and organizing a situation. These units may emerge multimodally, including through verbal explanations, numerical expressions, gestures, or interactions with digital environments. Hereafter, UIM will be used to refer to the referents that students pick up from a situation and use to make sense of it, which are viewed as units in their mathematizing process through the UIM lens. In the following sections, we illustrate how the UIM lens can be applied to an empirical dataset. The empirical excerpt is used not as evidence of the effectiveness of an LLM system, but as an illustrative case for showing the analytic value of UIM.

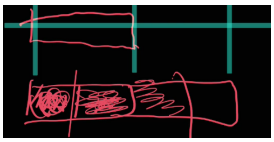
UIM applied in empirical data

The excerpt presented below is drawn from a larger empirical dataset and is used here to illustrate the UIM lens. Deborah (pseudonym), a fourth-grade student, engaged with a mobile game designed around fractions and was asked to explain how she interpreted the game situation. In her explanation (Figure 1), she described how the game used color-coded numbers to represent different aspects of the situation: green numbers indicated the number of wholes, and blue numbers indicated how those wholes were partitioned into pieces.

D: Deborah & R: Researcher - 1st Interview [17:40–20:19]	
R: Okay, so I'm supposed to have one whole, but because I have two in the blue box (Picture A), it got split up like this way, but this part is still visible and the other part is not solid? (Picture B) D: Yeah, like they're still both solid but they're just split. R: Oh, so you still have two, right? But this one is solid and this one is transparent? D: No, like it's like we have a whole here, right? R: We have a whole here, what do you mean here? Where is the whole?	 Picture A







D: So if I press the button (green box) and press 1, it makes this thing a full whole (Picture A), right? And then nothing on this will turn into transparent, we just split it, it didn't turn in transparent. R: But this part is transparent (pointing at the part from ½ to 1 in Picture A)? D: (a) Yeah I don't like, this is what I said, this could be easier if this right here (the whole) you can make a whole you can split it, but none of them turn transparent. Okay, so it's a whole right there, and you split it and like both of them are still solid (Picture C), they just split, they're still connected but split. Then there is another whole, if I can make another whole here and split this one, this one is solid and this one is transparent (Picture D)	 Picture B  Picture C  Picture D

Figure 1: Deborah's Explanation about the Blue and Green Numbers

Analyzed through the UIM lens, Deborah's explanation reveals a rigid UIM structure. Among various referents she recognized such as the color of the two numbers (green and blue), the changing number of green whole sticks, and the half of a green stick turning transparent, the referents she took up and used in her interpretation were 1) the number of green whole sticks, 2) the green numbers, 3) the fact that the green sticks were divided into pieces, and 4) the blue numbers. Drawing on these specific four UIMs in her mathematizing process, she consistently mapped the number of whole sticks to the green number*s*, while mapping the number of pieces into which each whole stick was divided to the blue number*s*. Based on this structure, the combination of green 1 and blue 2 should represent one whole stick divided into two pieces, with both pieces remaining solid in her interpretation. But she did not take up the half of the green stick becoming transparent as a UIM, even though she recognized it. She ended up rejecting it ("*I don't like*") because her UIM structure did not incorporate transparency as a UIM.

This case demonstrates that Deborah's challenge was not a lack of procedural skill but rather the rigidity of her UIM structure in interpreting the situation. Supporting her requires co-mathematizing to help her recognize and reorganize UIM structure, rather than simple corrective feedback. From this perspective, UIM can inform the future design of LLMs, whether through prompt engineering, fine-tuning, or other model-training approaches, by guiding them to attend to the UIMs students identify and coordinate in their interpretations of situations and to pose questions that invite reconsideration of what may count as a unit in a given context.

Units-In-Mathematizing (UIM) as a Framework for LLM Design

The UIM lens foregrounds students' interpretations of situations as central to understanding their mathematical thinking beyond correctness or procedural performance. In a UIM-informed design, the primary object of interpretation is not only the student's final answer, but also how the student organizes the situation: what is treated as a UIM, how UIMs are related, and how these relations change during mathematizing. Thus, rather than specifying a particular technical implementation, UIM lens offers a conceptual basis for future LLM-based instructional partners by clarifying what such systems should attend to, infer, and respond to in students' mathematical activity. Specifically, a UIM-informed system would attend to the units students foreground,

infer whether their difficulties involve procedural errors, unstable unit choices, or rigid UIM structures, and respond with questions that invite students to reconsider, coordinate, or reorganize UIMs. In this sense, the LLM is conceptualized less as a correctness evaluator and more as a co-mathematizing partner that engages with students' interpretive processes.

Illustrative Scenario: Problem-solving Focused vs. UIM-Based LLM Interaction

To illustrate this distinction, consider how two LLM-based interactions might differ. In a problem-solving-focused interaction, a student typically inputs a problem or attempts to solve a given task, and the LLM evaluates the correctness of the response and provides step-by-step feedback. This orientation explains why many studies focus on the accuracy of LLM-generated feedback in response to given inputs (e.g., Goel & Ghanta, 2025; Iqbal et al., 2026; Liu et al., 2025; Scarlatos et al., 2025). While such interactions can support procedural fluency and accuracy, they are not designed to examine how students make sense of the situation itself. As long as students produce the expected answer with an acceptable procedure, their underlying interpretation of the situation may remain unexamined, an issue long recognized in mathematics education research (e.g., Reusser, 1988).

In contrast, a UIM-based LLM interaction foregrounds identification of UIMs and UIM structures as central to the interaction. Rather than treating the student's answer as the primary object of evaluation, the system would treat the student's interpretation of the situation as the object of inquiry. For example, the LLM might introduce a situation that admits multiple interpretations: There are three baskets, each of which can hold five apples. If there are twelve apples, how full will the baskets be? Students' responses may vary, such as "two and two-fifths baskets," "twelve out of fifteen," or expressions of uncertainty. Each response may reflect a different choice of what counts as one whole: one basket, all three baskets together, individual apples, or another referent in the situation.

A UIM-informed LLM would use such responses not merely to determine whether the answer is correct, but to infer how the student is structuring the situation. It could then pose follow-up questions that make the student's unit choices explicit and open to reconsideration, such as "What does 'one' mean in your answer?" or "How would your explanation change if all three baskets together were considered one whole?" Such questions are not intended to lead students directly to a predetermined procedure, but to support their mathematizing by helping them examine and reorganize the units through which they interpret the situation.

Discussion and Limitations

This study proposes *Units-In-Mathematizing* (UIM) as a conceptual lens for rethinking the role of LLMs in mathematics education. Rather than positioning LLM-based AI as a tool for delivering personalized feedback or guiding students through procedural steps, UIM foregrounds students' mathematizing processes, specifically how they identify, coordinate, and reorganize units when interpreting situations mathematically. By illustrating how UIM makes visible aspects of students' mathematizing that may remain hidden in correctness-based assessments, this work contributes a theoretically grounded lens for designing future LLM-based instructional partners. Specifically, UIM shifts the focus of AI-mediated interaction from evaluating students' answers toward clarifying what such systems should attend to, infer about students' interpretations, and respond to in ways that support students' sense-making.

At the same time, this study is intentionally conceptual in nature and has several limitations. The framework has not yet been instantiated in an actual LLM through fine-tuning or prompt engineering, nor has its impact been empirically tested in authentic interaction settings. As a result, the present work does not provide evidence of learning outcomes associated with UIM-

informed AI design. Future research is therefore needed to operationalize this framework in concrete LLM implementations and to examine how UIM-based interactions shape students' mathematizing over time and support deeper mathematical understanding beyond procedural performance.

Professional noticing frameworks have significantly shaped how mathematics educators attend to, interpret, and respond to student thinking. However, traditional approaches often privilege verbal and written forms of expression, potentially overlooking tacit and embodied dimensions of reasoning. In this methodological brief, we introduce multimodal microanalysis, an approach that integrates professional noticing, embodied cognition, and microanalytic methods to systematically examine gesture, gaze, posture, and material interaction alongside speech. Using a cognitive interview with a second-grade student reasoning about even and odd numbers, we illustrate how sequencing attention to embodied and verbal modes reveals dimensions of mathematical thinking that are often missed. This brief highlights the methodological design and analytic insights that emerged from closely examining multimodal data. We argue that multimodal microanalysis advances professional noticing by offering a structured and replicable method for capturing tacit, embodied knowledge in mathematics learning.

Keywords: Teacher Noticing, Research Methods, Mathematical Representations, Teacher Educators

Professional noticing has been conceptualized as the interrelated practices of attending to students' strategies, interpreting their meanings, and deciding how to respond (Jacobs et al., 2010; van Es & Sherin, 2008). These practices have deepened the understanding of teacher learning and instructional responsiveness. Yet, much noticing research foregrounds what students say or write, privileging explicit knowledge while potentially overlooking embodied dimensions of reasoning. As a result, important evidence of student thinking may remain unexamined when it is expressed primarily through action rather than language.

Research in embodied cognition challenges this limitation, positing that mathematical reasoning is distributed across the body and environment (Nemirovsky & Ferrara, 2009; Nathan, 2021). Gesture, gaze, posture, and interaction with materials are not merely expressive but constitutive of cognition (Alibali & Nathan, 2012; Nathan, 2021). Students often demonstrate understanding physically before articulating it verbally. Despite this, professional noticing, embodied cognition, and microgenetic analysis have largely developed as parallel lines of inquiry rather than integrated methodological approaches. Bringing these traditions together creates opportunities to reconsider what counts as observable evidence of knowing in mathematics classrooms.

This brief report shares multimodal microanalysis as a methodological bridge among these traditions. The guiding question for our work is: How does multimodal microanalysis expand what mathematics teacher educators notice and interpret as evidence of student mathematical thinking? We found that by sequencing attention to embodied and verbal modes and by using

fine-grained video analysis, mathematics teacher educators can broaden what counts as evidence of knowing. In doing so, the approach reframes noticing as an inherently multimodal practice.

Theoretical Framing

Professional noticing involves attending to students' strategies, interpreting their mathematical meanings, and deciding how to respond instructionally (Jacobs et al., 2010). More recent scholarship has emphasized that noticing is shaped by teachers' lenses, identities, and sociopolitical contexts (Louie et al., 2021; Rubin & van Es, 2023). However, conventional noticing often prioritizes verbal articulation as the primary site of evidence, which may inadvertently position spoken explanation as the clearest indicator of understanding.

Brady et al. (2022) distinguish between explicit knowledge, which can be verbalized, and tacit knowledge, which is enacted through action and often remains unarticulated. When teachers attend primarily to spoken or written language, tacit dimensions of understanding may remain invisible. Embodied cognition offers a theoretical grounding for recognizing gesture, posture, and material engagement as integral to reasoning rather than peripheral to it (Nemirovsky & Ferrara, 2009; Nathan, 2021). From this perspective, the body is not simply a vehicle for communication but a site where mathematical ideas are formed and refined.

Multimodal microanalysis provides tools for examining learning at fine-grained time scales (Parnafes & diSessa, 2013). This approach captures moment-by-moment conceptual shifts that may occur prior to the more obvious linguistic and cognitive features. Multimodal microanalysis builds on microanalytic traditions while centering embodiment as a primary lens of interpretation. This integration supports a more comprehensive account of how mathematical thinking unfolds across time and modalities.

Multimodal Microanalysis

Multimodal microanalysis is a structured approach to analyzing video data in which embodied and verbal expressions are treated as equally central evidence of reasoning. The approach is characterized by intentional sequencing of modalities and slowed, repeated viewing. Following Radford (2009) and Sinclair (2024), we muted the audio during initial viewing to foreground gesture, gaze, and bodily action before interpreting speech. This sequencing was designed to prevent spoken language from prematurely shaping interpretation and to surface forms of reasoning that might otherwise be overshadowed by verbal explanation.

Video segments were analyzed at multiple playback speeds, including half speed and three-quarter speed, to detect subtle shifts in posture, hand movement, and gaze. Using ELAN software (Lausberg & Sloetjes, 2009), we created temporally aligned annotation tiers that distinguished learner embodiment, learner speech, instructor embodiment, and instructor speech. This layered structure allowed us to examine how modes overlapped, shifted, and interacted across time, making visible the coordination between bodily action and emerging verbal ideas.

Through collaborative coding and discussion, we developed shared interpretations of embodied utterances and their relation to verbal explanations. This process employed multimodal microanalysis as a methodological tool and a professional learning practice for mathematics teacher educators. Collaborative interpretation further supported analytic rigor by making possible researchers' assumptions explicit and open to negotiation.

Case Example

The case analyzed was a cognitive interview with a second-grade student asked to classify the number six as even or odd using blocks (Musser et al., 2013). Six mathematics teacher educators first engaged independently in traditional professional noticing. They documented the

student's verbal responses and observable strategies, establishing a baseline for comparison with the multimodal analysis.

We then selected a forty-second segment for multimodal microanalysis. Two researchers conducted initial ELAN coding, followed by collaborative refinement with the full research team. The aim was to examine what dimensions of reasoning became visible when attention was systematically directed toward embodiment before speech, thereby contrasting insights generated through conventional and multimodal microanalysis noticing.

Findings

Initial professional noticing captured that the student correctly identified six as even and used a pairing strategy with the blocks. The instructor's follow-up prompts were also noted. However, multimodal microanalysis revealed several dimensions that had not been documented in the original observations, demonstrating how analytic focus shapes what is ultimately recognized as evidence.

When first prompted to explain using blocks, the student's brow furrowed, and his gaze dropped toward the table. These embodied cues suggested uncertainty that was not reflected in his verbal assertion. Before manipulating the blocks, the student tapped the table three times, a subtle gesture that may indicate counting or cognitive processing. None of the researchers recorded this action during initial noticing, highlighting how quickly such movements can be overlooked in real-time observation.

The student engaged in two strategies. He first separated the blocks into two groups of three without verbal explanation. This fair-sharing attempt was often missed or uninterpreted during traditional noticing. He later grouped the blocks into three pairs and articulated a teacher-taught definition of evenness. Across these moments, gesture size and fluidity shifted. When uncertain, gestures were smaller and closer to his torso. As his explanation became more fluent, gestures expanded outward and speech became smoother. These changes in movement provided evidence of shifting engagement and understanding, suggesting a dynamic relationship between physical action and conceptual stabilization.

Multimodal microanalysis also surfaced features of the instructor's embodied behavior. Extended moments of stillness supported the student's independent reasoning. In certain instances, the instructor mirrored or echoed the student's gestures, creating embodied coordination that was not initially documented. These observations reframed the interaction as a coordinated, multimodal exchange rather than a purely verbal explanation, emphasizing the co-constructed nature of mathematical sensemaking.

Discussion

Multimodal microanalysis enabled us to broaden what counted as evidence of knowing. By foregrounding gesture, posture, and gaze, the research team recognized tacit dimensions of reasoning that speech alone did not reveal. What initially appeared as confident recall was reinterpreted as partially memorized knowledge supported by embodied experimentation, illustrating how multimodal evidence can refine instructional interpretations.

The structured sequencing of modalities proved essential. By muting audio first, researchers attended to embodied expression without being guided by verbal explanation. Slowed playback allowed for detection of subtle shifts that occurred too quickly to notice in real time. Layered annotation supported systematic comparison across modalities, strengthening the transparency and replicability of the analytic process.

Rather than replacing professional noticing, we assert that multimodal microanalysis extends it. The attending, interpreting, and deciding framework remains central, but what is attended to is expanded. The combination allows embodied utterances to shine as legitimate and analyzable evidence of mathematical offering deeper intuition reasoning. positioning the body as a meaningful source of data rather than contextual background.

Methodological Contribution

This work contributes a methodological extension of professional noticing. Multimodal microanalysis integrates embodiment and microanalytic precision building onto teacher noticing research. It offers procedural guidance for sequencing attention, structuring analysis, and collaboratively interpreting multimodal data. By doing so, it clarifies how mathematics educators can systematically capture mathematical knowledge expressed through bodily action, thereby supporting richer accounts of student thinking and interaction. Figure 1 shows a conceptual framework for this methodological contribution that advances professional noticing by systematically incorporating embodiment into the interpretation of student thinking.

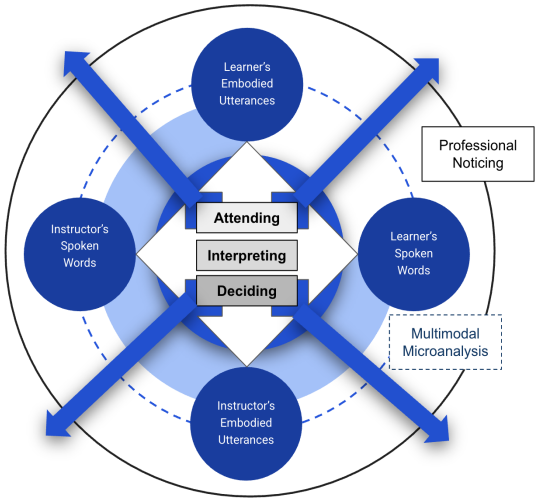

Figure 1: A Conceptual Framework for the Interplay of Professional Noticing and Multimodal Microanalysis Supported by Embodiment

Limitations and Future Directions

Multimodal microanalysis is time-intensive and best suited for focused case studies or short video segments. Interpretive bias remains a consideration, requiring collaborative triangulation and reflexivity. Future research might explore how elements of multimodal microanalysis can be adapted for teacher professional development contexts where time constraints are significant, as well as how the approach might inform the design of noticing-focused learning experiences for educators.

Conclusion

Mathematics learning involves coordinated representations, spatial reasoning, and bodily engagement (Lesh et al., 1987; NCTM, 2014). Research methodologies must likewise account for these dimensions. Multimodal microanalysis extends professional noticing by systematically incorporating embodied cognition into analytic practice. By broadening what counts as evidence

of mathematical thinking, this approach enhances research on teacher learning and supports more comprehensive interpretations of student reasoning, ultimately encouraging mathematics educators to notice not only what students say, but also what their bodies reveal about emerging understanding.

TEACHERS' PERCEPTIONS AND PREPARATIONS FOR GENERATIVE ARTIFICIAL INTELLIGENCE: SURVEY RESULTS FROM MISSOURI AND TEXAS

PERCEPCIONES Y PREPARATIVOS DE LOS DOCENTES PARA LA INTELIGENCIA ARTIFICIAL GENERATIVA: RESULTADOS DE UNA ENCUESTA DE MISSOURI Y TEXAS

Samuel Otten	Tiffany J. LaCroix	John K. Lannin
University of Missouri	University of Missouri	University of Missouri
ottensa@missouri.edu	tlacroix@missouri.edu	lanninj@missouri.edu

This brief report examines K–12 mathematics teachers' responses (n = 811 from Missouri and Texas) to a survey about their preparedness for and perceptions of generative AI (GenAI). The survey was a mathematics adaptation of the LEAP-AI instrument (von Gillern et al., 2025) and generated quantitative and qualitative data. Findings indicate moderate confidence with general technology but lower confidence with GenAI for instruction and mixed views on mathematics teachers' responsibilities relative to students' learning of GenAI. Teachers identified content generation and lesson planning as primary affordances of GenAI, alongside concerns about student overreliance and academic dishonesty. State-level differences were observed.

Keywords: Teacher Beliefs, Technology

As technology companies race forward into the artificial intelligence revolution, educators and education scholars are trying to understand the potential benefits and the likely dangers of these technological advances with regard to students. Of particular importance is generative artificial intelligence (GenAI), which is AI designed to produce outputs (text, images, audio, etc.) for a user (e.g., ChatGPT (OpenAI, 2023), Gemini (Google, 2004), and Claude (Anthropic, 2024). GenAI's capabilities go well beyond prior technological revolutions in mathematics education such as calculators (Penglase & Arnold, 1996), dynamic geometry software (Oner, 2009), or problem-solving smartphone apps (Webel & Otten, 2015), though GenAI is still unreliable and requires a diligent user (McGalliard & Otten, 2024; Walkington, 2025). Nevertheless, diligent and non-diligent students seem to be using GenAI to a noticeable degree, as evidenced by sharp declines in GenAI usage after the school year concludes (Burman, 2025).

As these technologies rapidly impact students, it is important to consider and listen to teachers as those who are on the front lines of the revolution, using GenAI themselves and guiding students in its ethical use. In this brief report, we share findings from a survey of 811 K-12 mathematics teachers across Missouri and Texas. The survey pertained to their confidence with technology and their opinions regarding GenAI, including open-ended questions about their opinions on benefits and concerns about GenAI in mathematics education.

Background Literature and Theoretical Perspective

Although we focus this work on teachers, students' perspectives are also worthwhile. Kibici (2025), for example, found a position relationship among university students between digital literacy skills and positive attitudes toward GenAI, as one might expect, and although GenAI was viewed favorably overall, the students had concerns about creative works and ethical use of GenAI. At the middle school level, Adisa and Adefisayo (2025) found that students can have quite nuanced opinions about the use of GenAI in school, shaped by their desires for ownership over learning (or not) and their desires for relationships with human educators (or not).

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Although students may use GenAI of their own volition, for the field of mathematics education broadly it will be crucial to understand teachers' perspectives. Research in this area is still emerging, but relevant studies have been conducted in other areas of education. Working at the university level, Alenezi (2024) found that instructors generally see positive potential for GenAI in education but had relatively low intentions to actually adopt GenAI. At the school level, in literacy education, von Gillern et al. (2026) identified several concerns raised by teachers about GenAI, including the unreliability of the outputs and the potential for cheating by students. They also saw benefits, however, such as time efficiency for themselves as teachers and the potential of automated feedback for students and preparation for an unknown future. Within mathematics, specifically, Busuttil and Calleja (2025) found that teachers who value student discovery and meaningful connections did tend to see a potential role for GenAI in students' learning, but professional development may be centrally important in helping teachers discern how to incorporate the technology into their teaching.

Much work remains to be done on the ethics of GenAI in education (Akgun & Greenhow, 2022) and pedagogical theorizing around the integration of GenAI into teaching and learning (Erduran & Levrini, 2024), but we hope to contribute an illumination of the current landscape in terms of mathematics teachers' perceptions of GenAI. In particular, we seek to answer the following research questions drawing upon a survey of K-12 mathematics teachers:

1. What level of agreement did mathematics teachers express with regard to their preparedness to use GenAI and their responsibility to teach students about GenAI?
2. What benefits of and concerns about GenAI did mathematics teachers describe?

Method

Participants in this study were respondents to a survey distributing electronically to email lists of all certified teachers in Missouri and Texas, specifically, all teachers of grades K–5 and all teachers with mathematics certification in grades 6–12. We received 811 responses (459 from Missouri, 352 from Texas) and although response bias is likely, with the explicit topic of GenAI in the survey invitation and with approximately 4 times as many secondary teachers responding than elementary teachers, a direct inspection revealed reasonably similar responses on all Likert-items between the two subgroups, and the respondents exhibited demographics relative to age, teaching experience, and race that were fairly consistent with state demographics.

Drawing upon survey design methodology (Dillman, 2011), this study involved an adaptation of a GenAI-perception survey for literacy teachers (von Gillern et al., 2025), Literacy Educators' Attitudes and Perceptions on Artificial Intelligence (LEAP-AI), revising the items to relate to mathematics teaching and learning. Validation of this revision with regard to the factor structure is ongoing, but descriptive statistics of key single items are reported here, as shown below, using only the responses of teachers who completed at least 85% of the survey (n = 758).

With regard to the open-ended items, the survey included the following questions: "In what ways do you think AI could be beneficial to math instruction?" and "What are you biggest concerns about AI related to math instruction?" These responses were open coded within the Qualtrics survey software and then two co-authors met to reach an acceptable level of inter-coder agreement. Subsequently, a second round of thematic coding took place to collapse and clarity the results of the first round. Due to space limitations, only the predominant themes are reported below, with data excerpts presented but with no distinctions between subgroups of respondents.

Findings

Mathematics Teachers' Feelings of Preparedness to Teach with GenAI

Table 1 displays results for key items from the LEAPS-AI survey adapted for mathematics teachers, all answered on a 5-point Likert scale (1 = strongly disagree, 5 = strongly agree). Note that teachers in Texas tended to have higher levels of agreement than teachers in Missouri. This was true across all Likert-scale items.

Table 1: Teachers' Level of Agreement to Various Statements About Technology and GenAI

Survey Item	In general, I am confident in my ability to effectively integrate educational technologies.	I am confident in my ability to effectively use GenAI for personal purposes.	I am confident in my ability to effectively use GenAI for educational purposes.	It is important for math teachers to understand how to create effective prompts for GenAI.	It is important for math students to understand that GenAI texts often include inaccuracies.	Math teachers should be responsible for teaching students to use GenAI in different educational scenarios.
MO (*n*=482)	3.02	2.70	2.45	3.11	3.27	2.61
TX (*n*=276)	3.96	3.46	3.20	3.92	4.04	3.54
St. Dev. on item overall	0.88	1.11	1.13	0.90	0.93	1.11

Moving left to right in Table 1, the teachers tended to not feel unconfident about their technology skills in general, with Texas teachers reporting fairly high levels of confidence, but the confidence levels related to GenAI were markedly lower, which makes sense given the relatively new emergence of GenAI. Teachers in both states tended to be slightly more confident about personal use of GenAI than educational use. Texas teachers tended to agree that teachers should understand effective prompting with GenAI and that students should be aware of potential inaccuracies from GenAI (Missouri teachers did not disagree), but results were mixed on the teachers' responsibility. Texas teachers tended to slightly report an agreement that mathematics teachers should bear responsibility in developing students' GenAI skills, but Missouri teachers tended to slightly disagree with this statement.

Teachers' Descriptions of the Potential Benefits of GenAI in Mathematics Instruction

A majority of teachers reported GenAI could be a beneficial tool for creating mathematical situations (e.g., word problems, activities) they could use in their classrooms. Many teachers further specified that GenAI could be helpful in creating content that contained real world connections for students or that differentiated the activities for specific students. For example, a Missouri teacher stated that "AI can help generate problems when we are looking for some more practice […] like, coming up with an equation and putting a back story to it to create a word problem." A Texas teacher also reported actually taking advantage of these sorts of benefits:

> We use AI to diagnose students' learning levels and then tailor instruction to them at that level or slighter harder. It also learns their likes and dislikes to help offer them subjects/topics they prefer compared to non-preferred subjects/topics.

Overall, 390 teachers (51%) specifically mentioned content creation as a benefit of GenAI.

The other predominant theme in the survey responses was the related but distinct notion of lesson planning. A total of 168 teachers (22%) described how GenAI could be beneficial for lesson planning in general or for specific aspects of the planning process, beyond the creation of just individual elements (captured above). For instance, one Texas teacher wrote that GenAI could be used to not only generate problems but "differentiation [the problems] according to each student's needs" as part of the lesson overall, and assisting with the accompanying instruction because the "AI could help demonstrate the steps used to solve each problem."

Other benefits mentioned less often had to do with translating or supporting English learners, providing mathematical support at home, or generally enhancing interest in mathematics in some manner. It should be noted, however, that even on an item about GenAI benefits, 77 teachers (10%) expressed that there might not be benefits or were adamant that GenAI should not be used in mathematics education, which brings us to the next section of results.

Teachers' Descriptions of Concerns about GenAI in Mathematics Teaching and Learning

Most of the concerns teachers had about GenAI in mathematics instruction had to do with their perceived effects on students. There were two primary themes, having to do with a potential negative impact on students' learning, due to their overreliance on the capabilities of GenAI, and also the concern over cheating or academic dishonesty. The two themes may be implicitly related as cheating may undermine a students' depth of learning but can also be a concern in its own right. An example of such concerns as stated by a Missouri teacher is as follows:

> One of my biggest concerns about AI in math instruction is the potential for over-reliance on it, which might reduce critical thinking and problem-solving skills in students. While AI can generate quick solutions and detailed explanations, there's a risk that learners might depend too much on AI-generated answers without fully understanding the underlying concepts.

In total, 239 teachers (32%) expressed concern about detriments to student learning and 220 (29%) expressed concerns about academic dishonesty (and some teachers expressed both and are included in both counts). Note that here, as in the benefits section, the item was open ended and so teachers did not necessarily write about *all* of their concerns (or perceived benefits).

Teachers also expressed concerns related to GenAI's effect on their own work in teaching. One teacher from Missouri wrote, "My biggest concern is that AI is becoming another technology that teachers are not trained to use and therefore cannot appropriately teach their students to use." This response suggests that there may be a beneficial way to use GenAI with students, but teachers may not be equipped to do so and thus, with teachers as the conduit, it is an area of concern. A Texas teacher alluded to the relational work that is central to teaching, stating, "My biggest concern is getting away from the personalized connections formed between teachers and students." Others expressed that it was troublesome to think about the time it would take to learn GenAI when they are already overburdened with existing responsibilities. Overall, however, these teacher-focused themes were not as prevalent as the student-focused ones, with only 71 teachers (9%) expressing concerns rooted in teaching or teachers.

Discussion

Amidst a frantic shift toward GenAI in various aspects of life, including education, we took a moment to collect and consider the perspectives of mathematics teachers from two states in the U.S. The teachers expressed mixed levels of agreement about aspects of teaching and using GenAI, with substantial individual variation and also marked differences between Missouri and Texas (perhaps because of contextual differences between the states or because of a response bias with relatively fewer responses from Texas). Teachers described various benefits and

concerns about GenAI in mathematics education, exhibiting their consistent concern for students above all else. These findings corroborate past research and provide insight into teachers' mindsets as we promote, critique, or design professional development related to GenAI.

Acknowledgments

This work was supported by the Richard G. Miller endowment at the University of Missouri. We thank the teachers for sharing their perspectives and we thank Sam von Gillern, Gary Wright, Emmanuel Umeh, Miriam Kabagorobya, and William McGalliard for their insights.

PRESERVICE TEACHERS' TPACK DEVELOPMENT WHEN INTEGRATING DIGITAL MATH GAMES INTO FRACTION LESSON PLANS

Allison L. Roxburgh
Idaho State University
allisonroxburgh@isu.edu

This Brief Research Report examined how 22 elementary preservice teachers developed their technological pedagogical content knowledge (TPACK) when integrating digital math games into fraction lesson plans. Data from pre- and post-surveys and a fraction lesson plan were analyzed by summarizing survey data, using stacked bar graphs, and categorizing lesson plans by TPACK developmental levels. Findings showed preservice teachers' lesson plans had three distinct developmental levels: Recognizing, Accepting, and Adapting. These results suggest that preparation programs need to bridge the gap between preservice teachers' reported confidence and their practical integration of digital math games.

Keywords: Preservice Teacher Education, Technology, Elementary School Education

As educational games become common in K-12 classrooms, preservice teachers (PSTs) must learn to effectively integrate these tools into instruction. Integrating digital math games (DMGs) requires synthesizing content, pedagogy, and technology, a process analyzed through the Technological Pedagogical Content Knowledge (TPACK) framework (Mira & Koehler, 2006). This Brief Research Report examines PSTs' TPACK development as evidenced in their self-reported survey responses and fraction lesson plans. This mixed methods study (Creswell & Plano Clark, 2017) aims to provide insights into how to better support PSTs in their TPACK development and improve their abilities to integrate DMGs into mathematics lessons.

Literature Review

Many new teachers are entering the profession underprepared to integrate technology into their instructional practices (Gudmundsdottir & Hatlevik, 2017; Meaney et al., 2023). To better prepare these educators, teacher preparation programs must incorporate frameworks and tools, like DMGs, which effectively support mathematics understanding (Bullock et al., 2020; Falloon, 2013; Kärki et al., 2021; Ke & Abras, 2013; Moyer-Packenham et al., 2019). Specific design features within a DMG actively supports students' mathematics learning (Bullock et al., 2020; Falloon, 2013; Ke & Abras, 2013; Moyer-Packenham et al., 2019). Among the eight mediating design features identified by Moyer-Packenham et al. (2019), standard instructional scaffolds like hints and feedback were reported to be essential, but linked representations and linked physical actions uniquely support students' mathematical understanding. Because these particular features allow students to directly interact with mathematical concepts through physical movement or representational connections, teacher must recognize them when choosing and evaluating DMGs for instruction. In this study, these design features guided the learning module as the specific technology game knowledge PSTs need to effectively integrate DMGs.

This specialized knowledge forms a key component of the Technological Pedagogical Content Knowledge (TPACK) framework (Mishra & Koehler, 2006), a widely used lens for examining the dynamic relationships among a teacher's technology, pedagogy, and content knowledge (Gutiérrez-Fallas & Henriques, 2021; Lachner et al., 2021; da Silva Beuno & Niess 2023). Hsu et al. (2013, 2017, 2020) extended TPACK to include game-specific dimensions (TPACK-G): game knowledge (how to play); game pedagogical knowledge (how to teach with

games) and game content knowledge (how the game represents content). This study used TPACK-G to analyze PSTs' development from pre- to post-survey.

Furthermore, research suggests that teachers' TPACK progresses through five levels of development (Niess et al., 2010; Niess & Gillow-Wiles, 2013): (1) *Recognizing* how technology aligns with content topics, (2) *Accepting* beliefs (positive or negative) about teaching with technology in relation to specific grade levels, (3) *Adapting* tasks by choosing appropriate technologies for instruction, (4) *Exploring* how to effectively implement appropriate technologies in their content areas, and (5) *Advancing* their integration of technology by reflecting on their instructional practices and making changes based on that reflection. While previous studies have utilized this development framework (da Silva Bueno et al., 2023; Kartal & Çinar, 2024; Lyublinskaya & Kaplon-Schilis, 2022), few focus on DMG integration in mathematics. Integrating DMGs is different from using traditional classroom technologies because games have their own internal rule systems and structures. As a result, the DMG context introduces a notable tension between how a teacher wants to guide instruction and how the game's specific design features shape how students interact with the game (Hsu et al., 2013). Therefore, this study uses these levels to categorize PSTs' TPACK-G within their lesson plans, tracking their progress from basic awareness of games for instruction to advance ability to leverage specific design features as core pedagogical tools.

Methods

As part of a larger convergent mixed methods study (Creswell & Plano Clark, 2017), this Brief Research Report addresses the research question: How do preservice teachers TPACK-G survey responses, before and after a learning module, relate to the development levels of TPACK development level demonstrated in post-module their lesson plans? With two guiding sub-questions: (1) What changes, if any, are observed in preservice teachers' TPACK-G survey responses from pre- to post-survey? and (2) How do preservice teachers' lesson plans demonstrate levels of TPACK development?

Participants and Procedures

Participants included 22 elementary PSTs recruited from four semesters of an asynchronous online math methods course from one university. Participant demographics were not collected; however, the university's population is predominantly white (72%), with approximately 57% identifying as female and 43% identifying as male, providing context for the participant sample. Over a three-week instructional module focused on TPACK and DMGs, participants completed a pre-survey, engaged in a learning module on evaluating and integrating DMGs, developed an inquiry-based lesson that integrated a DMG; and completed a post-survey.

Data Sources and Analysis

Data sources for this brief report included PSTs pre- and post-survey responses and their fraction lesson plans. The surveys included 13 Likert scale items measuring agreement, adapted from established TPACK-G literature (Hsu et al., 2013, 2017, 2020). For example, Hsu et al. (2017) used the statement, "I can identify the knowledge related to the subject matter in digital games." In this study, this was adapted to, "I can identify the knowledge related to the mathematics in digital math games." The survey also included two open-ended questions related to game familiarity and game design features. The post-survey included the same items as the pre-survey, but in a randomized order. Finally, PSTs' lesson plans followed the "Launch, Explore, Discuss" framework (Markworth et al., 2015), chosen to shift PSTs focus from explicit instruction toward inquiry-based planning that supports student exploration with DMGs.

To analyze the quantitative data, stacked bar graphs summarized the percentage distribution

and frequencies of PSTs Likert scale ratings (Cooksey, 2020; South et al., 2022) to visually track shifts from pre- to post-survey. Deductive protocol coding (Saldaña, 2021) was used to qualitatively analyze PSTs' lesson plans. The operational definitions for Niess et al.'s (2010) levels of TPACK development (e.g., recognizing, accepting, adapting) served as the coding scheme. Each lesson plan was segmented by structural components (launch, explore, discuss) and analyzed for evidence of game-based mathematical pedagogy. To maximize interpretive reliability, a detailed codebook was used. Survey results and lesson plan codes were compared to explore how changes in self-reported TPACK-G related to PSTs planning decisions.

Results

Analysis revealed positive shifts in PSTs' self-reported TPACK-G from pre- to post-survey, as shown in Figure 1, by a shift from disagreement (red/orange bars) to agreement (blue/green bars). For example, for the statement "I have adequate training to integrate DMGs into mathematics instruction," pre-survey responses favored the disagree portion of the Likert scale (59%, n = 13 Disagree/Strongly Disagree; 27%, n = 6 Neutral; 14%, n = 3 Agree/Strongly Agree). However, on the post-survey PSTs' responses noticeably shifted toward the agree portion of the Likert scale (0% disagree; 5%, n = 1 Neutral; 96%, n = 21 Agree/Strongly Agree). Eight other survey items showed a similar positive trend. Three statements maintained high neutral-to-agree ratings on pre- and post-survey, indicating that positive views towards DMGs were already established at the beginning of the study. In contrast, the statement, "I have no idea how to integrate DMGs into my curriculum," was the only item to shift toward the disagree portion of the scale (95%, n = 21 Disagree/Strongly Disagree; 5%, n = 1 Neutral); however, this statement is negatively phrased, which actually represent a positive shift in self-reported confidence. These combined shifts demonstrate a clearer self-reported understanding of how to integrate DMGs and indicates a broader trend of growth in PSTs' overall self-reported confidence.

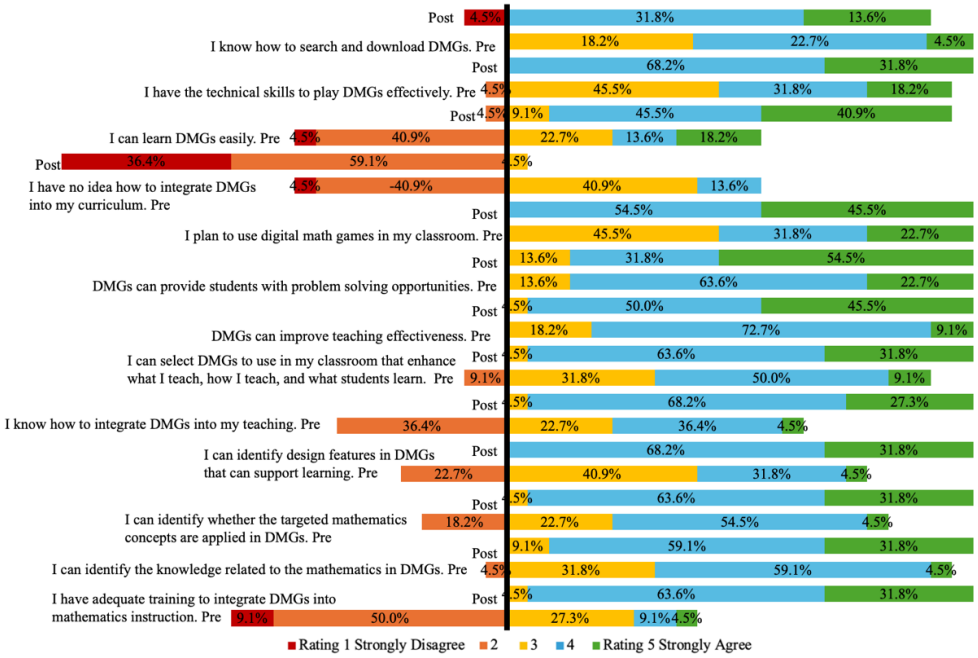

Figure 1: PSTs TPACK-G Pre-Survey and Post-Survey Responses

PSTs lesson plans had three distinct developmental levels that emerged: Recognizing, Accepting, and Adapting. Several PSTs (41%, $n = 9$) demonstrated the Recognizing level by showing awareness of the DMGs, but using the games solely as practice-based or motivational support. For example, one PST described the integration of the game as "Students will practice (by using the game) counting by ones, tens, and hundreds using base ten blocks." Thirty-six percent of PSTs (n = 8) reached the Accepting level, using DMGs to support learning, but limiting student learning through direct instruction or teacher-led demonstrations. For example, one PST wrote "I will use explicit instruction to show students how to navigate the website." Another PST wrote, "Teacher guides step, by step during play." Few PSTs (23%, $n = 5$) showed the Adapting level when they thoughtfully integrated DMGs and asked meaningful questions to support student learning. For example, one PST asked, "Who can explain how it went about finding three fractions that were equivalent in the game?" Another PST asked a specific question related to the game when they asked, "Look at this Triplet. How do we know these three go together?" Comparing these levels to the post-survey results (Figure 1) revealed a disconnect between perception and practice. Many PSTs at the Recognizing and Accepting levels reported high confidence in their ability to integrate DMGs and identify design features, yet their lesson plans reflected limited implementation of DMGs for instructional practice.

Limitations

While this study offers valuable insights, several limitations must be acknowledged. First, the findings may not be generalizable beyond the participants in this study due to the study's short duration and small sample size. Additionally, self-reported data may not fully reflect PSTs actual knowledge or skills for integrating DMGs into mathematics instruction. Finally, the use of a single coder for qualitative analysis may introduce subjectivity and limit the reliability of interpretations. Future research should include larger cohorts and multiple coders to help address these boundaries.

Discussion and Conclusion

While findings indicate a moderate increase in PSTs self-reported TPACK-G following the learning module about DMGs, this perceived growth was not yet reflected in their actual lesson plans. This suggests that while the learning module successfully fostered TPACK-G confidence, translating that confidence into practice remains a challenge. These findings extend the TPACK-G framework by demonstrating that its knowledge dimensions do not develop simultaneously, suggesting misalignment between PSTs' evolving game-related pedagogical beliefs and their ability to translate those beliefs into effective lesson planning.

This structural discrepancy suggests that the framework's developmental progression includes a critical transition point between the "Accepting" and "Adapting" levels. Therefore, this study concludes that while the learning module was an effective tool for shifting PSTs perspectives about DMGs, it must be paired with a deeper, scaffolded practice to translate these gains into practice. In practice, this scaffolding could include providing lesson plan templates with prompts for DMG design features, or utilize peer co-planning sessions where PSTs collaborate to plan lessons that integrate a DMG. Ultimately, teacher education need to include designing experiences that not only build PSTs confidence with integrating DMGs but also ensure the growth is reflected in observable teaching practices. Future research should continue to examine the specific, practical support necessary for PSTs to successfully shift from positive perspectives about DMGs to high-quality DMG integration.

AI-generated feedback can help teachers focus on students' mathematical reasoning by annotating student work to promote engagement and mathematical thinking. Using the Math Forum data corpus, a dataset of mentor feedback to student work and reasoning, we built a Retrieval-Augmented Generation (RAG) model to generate feedback using the noticing and wondering framework. We evaluate this AI system using our dataset against a similar AI system without this added training data, and against an AI system fine-tuned with the Math Forum training data, to determine the viability of a RAG approach to generating feedback. The RAG model tended to focus responses on procedural correctness, while the fine-tuned model centered on student reasoning and process. Our findings suggest that a fine-tuned approach may better direct AI generations but should be coupled with human supervision.

Keywords: Technology, Teacher Noticing

As recent advances in generative AI have emerged, there is greater attention focused on how teachers might integrate this evolving technology into their classroom practices (Holmes et al., 2019; Zafari et al., 2022). We have seen success with these tools as direct-to-student tutors, however they often lack the pedagogical sophistication needed to provide feedback that builds on student thinking rather than simply correcting errors (Stein et al., 2008). Our work investigates whether AI might serve as a support tool that helps teachers draft and refine feedback more efficiently while also retaining their role as the primary mentor.

This study draws on a valuable resource: the Math Forum's thirty-year collection of mentor feedback on students' mathematical thinking across a wide range of "Problems of the Week." This archive extends beyond pairs of student work and mentor responses. It includes rich, paragraph-length explanations of student reasoning spanning multiple grade levels and mathematical standards, capturing both correct and incorrect approaches. Using this unique dataset, we ask whether integrating historical mentor feedback through Retrieval-Augmented Generation (RAG) can enhance the quality of AI-generated feedback.

We compare three AI models in this work: a baseline model with no specialized training, a RAG model informed by Math Forum data, and a fine-tuned model trained on the same data with additional instructional guidance. Through qualitative analysis, we examine whether the draft feedback from each model provides teachers with material they can meaningfully refine and whether it reflects the discourse patterns characteristic of high-quality mathematical mentoring.

Theoretical Framework/Conceptual Framework

This study draws on two key frameworks: Hattie and Timperley's (2007) model of effective feedback and Stein et al.'s (2008) framework for productive mathematical discourse. Together, they define high-quality mathematical feedback as feedback that clarifies goals, responds to

students' current thinking, and supports next steps without lowering cognitive demand. Effective feedback builds on students' reasoning, including partially correct or incorrect ideas, while maintaining their agency as sense-makers (Stein et al., 2008).

Our interdisciplinary team of mathematics educators and AI researchers works within a pipeline designed to generate and analyze AI-produced feedback. Providing strong feedback requires instructional judgment that goes beyond checking correctness: teachers must identify productive ideas in flawed reasoning, anticipate misconceptions, and determine what to address in the moment. These judgments are highly contextual and cannot be reduced to fixed rules.

Guided by these frameworks, we investigate whether Retrieval-Augmented Generation (RAG) can help AI systems approximate aspects of expert feedback by grounding responses in mentor exemplars. Using the Math Forum's rich corpus, we examine whether AI-generated drafts reflect core principles of effective mathematical feedback. Our goal is not to replace teachers, but to evaluate whether theoretically informed training data can produce AI drafts that meaningfully support teacher refinement.

Literature Review

Research on AI in mathematics education shows mixed outcomes. Some scholars argue that AI can ease teachers' workloads by reducing time spent on grading and feedback, potentially allowing more time for planning and individualized support (Owan et al., 2023). Yet despite performing well on many undergraduate-level tasks, AI systems often struggle with more complex mathematical reasoning and frequently miss students' underlying misconceptions (Frieder et al., 2023). As a result, AI-generated feedback tends to prioritize procedural accuracy over the reasoning-focused, adaptive feedback known to support deeper mathematical learning (Stein et al., 2008).

A key limitation in current research is the limited attention to the pedagogical sophistication of AI outputs. Many studies assess correctness or efficiency rather than examining how AI responds to different forms of student thinking (Holmes et al., 2019). In contrast, effective mathematical feedback relies on recognizing productive ideas within incorrect reasoning, anticipating likely misconceptions, and making moment-to-moment decisions about what to address, skills that require specialized pedagogical knowledge (Mishra & Koehler, 2006). Although AI can produce fluent, teacher-like language (Case et al., 2025), this surface-level appropriateness may conceal misunderstandings or lead to unproductive moves such as excessive praise, undermining student agency, or reducing cognitive demand (Dweck, 2007).

This study examines whether Retrieval-Augmented Generation (RAG), which draws on relevant historical examples, can improve the pedagogical quality of AI-generated feedback when trained on expert mentor responses. Using Encompass, a professional development platform that supports teachers in analyzing student thinking through structured noticing and wondering, we compare feedback from three AI models. Our goal is not only to determine whether AI feedback is mathematically accurate, but whether it demonstrates the kinds of pedagogical moves that build on student thinking, sustain cognitive engagement, and position learners as capable mathematical thinkers.

Methodology

We conducted a qualitative, memo-based analysis of AI-generated feedback on 100 samples of student mathematical work across three model conditions: a base model, a RAG model, and a fine-tuned model. For each condition, AI feedback was paired with the corresponding student work (see Figure 1, Adapted from Problem of the Week: Birthday Trip, by National Council of

Teachers of Mathematics), and analytic memos were created through close reading to capture patterns in mathematical accuracy, attention to student reasoning, pedagogical stance, and instructional usefulness.

Our approach followed an iterative, inductive process grounded in memo-based and constant comparative methods (Miles, Huberman, & Saldaña, 2014; Charmaz, 2014). Memos were grouped into higher-level patterns without predefined codes, and memo titles were retained as analytic artifacts to maintain proximity to researchers' observations. Throughout the process, team members discussed emerging themes, using disagreement and surprise as productive analytic tools rather than indicators of unreliability (Erickson, 1986). This allowed us to identify stable failure modes, shifts across model conditions, and design-relevant tensions in how AI systems interpret and respond to student mathematical thinking.

Jade's family is planning to travel to her Aunt Mazie's house to celebrate Aunt Mazie's 102nd birthday. On the first day of the trip they'll drive halfway there and then stop to set up camp for the night. On the second day of the trip they'll drive two-thirds of the remaining distance before stopping for some sightseeing and camping. On the last day they'll have 145 miles left to drive.

Question: How far is the trip to Aunt Mazie's house?

Extra: If the family averages 50 miles per hour while driving on the return trip, do you think the family will make the trip in one day? Why or why not?

Figure 1: Birthday Trip Problem

We used a llama3-based large language model (LLM) and augmented it with a RAG system built from the Math Forum training corpus. The corpus was embedded using the intfloat/e5-large-v2 model in 512-token windows with a 50-token overlap to maintain contextual coherence between student reasoning and mentor responses. For each student submission, we embedded the problem statement, all student messages, all mentor feedback, and associated metadata such as timestamps and rubric scores. The fine-tuned model was trained on NousResearch's Nous-Hermes-2-Mistral-7B-DPO (Teknium et al., 2024), which supports parameter-efficient fine-tuning. Both the RAG and fine-tuned models were trained on a dataset containing math problems, student solutions and resubmissions, mentor feedback, and rubric evaluations.

Results

Across all three conditions, a central challenge persisted: models struggled to make instructionally appropriate judgments about student work, particularly distinguishing between students who were mathematically incorrect and those who were correct but insufficiently explicit in their explanations. Changes in model configuration altered how errors manifested, but did not eliminate the underlying difficulty of deciding when to correct, probe, extend, or conclude.

Baseline Model: Fluent but Obscuring

Baseline feedback often sounded teacher-like and supportive, yet masked mathematical or interpretive weaknesses. The model frequently reframed student work into generic instructional extensions, which diluted attention to the student's actual reasoning needs (e.g., clarity of explanation) and could obscure key misunderstandings.

RAG Model: More Directive, Higher-Risk Distortions

RAG changed the character of errors. Feedback more often included overt mathematical inaccuracies (e.g., mislabeling correct work as incorrect) and sometimes introduced irrelevant interpretations. These failures were frequently paired with a more corrective tone, increasing the risk of undermining student agency and teacher trust even when the language appeared "instructional."

Fine-Tuned Model: Improved Fidelity with Persistent Overreach

Fine-tuning produced notable improvement in recognizing mathematically valid reasoning and adopting a more sense-making stance (e.g., questioning rather than correction). However, outputs frequently introduced unnecessary strategy naming or probed without sufficient specificity, revealing continued difficulty deciding when feedback should stop.

Cross-model Case Illustrating AI Instructional Challenges

One illustrative case (student 71531) highlights how the same incorrect solution elicited meaningfully different responses across conditions. The student concluded the trip was 435 miles by treating 145 miles as one-third of the trip and multiplying by three, a move that reflected a misinterpretation of the problem context rather than a computational error. The baseline model affirmed the multiplication and extended into unrelated ratio talk, masking the core issue. The RAG model adopted a corrective stance but reframed the issue as a procedural misunderstanding, mischaracterizing the student's shared thinking. The fine-tuned model recognized the proportional reasoning as productive yet still did not name the incorrect conclusion, shifting instead to reflective prompts. Across all three, the central instructional issue, misalignment between the student's reasoning and the problem context, was not clearly surfaced. Model modifications changed the form of feedback and the visibility of errors, yet did not resolve the difficulty of deciding whether to correct, probe, extend, or conclude.

Significance, Limitations, and Conclusions

This study reframes evaluation of AI feedback on student thinking from correctness and fluency toward a more pedagogically sound decision-making process. By comparing baseline, RAG, and fine-tuned configurations using qualitative memo analysis, we surface design-relevant failure modes (e.g., fluent masking, directive distortions, task overreach) that can inform more responsible teacher-facing tools.

Results support a teacher-in-the-loop framing: AI is most plausibly useful as a drafting support that teachers refine, not as an autonomous feedback provider. Even when trained on a corpus of mentoring data, models may fail in ways that require human pedagogical intervention, not merely error-checking.

Three limitations surfaced in this study: (1) RAG retrieves only a small number of exemplars, which may not match a student's underlying conceptual need; (2) text-generation models may produce mathematically inaccurate statements; (3) some outputs drift toward generic praise or unnecessary extension. Future work will test retrieval strategies that prioritize high-quality mentor exemplars and explore workflows that make teacher review efficient while preserving pedagogical intent.

For this study, the researchers used three generative AI models to create 25 K-12 mathematical word problems, some with images, that they then evaluated for mathematics quality and problem context. Numerous concerns appeared in both categories. The problems tended to be mathematically simplistic for the intended grade level, with key words appearing in more than half the problems. Images often presented confusing or conflicting information in relation to the textual problem, and incidents of social class, racial, and gender bias appeared in the text or images of a number of problems. Using GenAI to create grade-level-appropriate word problems bears promise but must be viewed critically at this point in time.

Keywords: Problem-Solving; Technology; Equity, Inclusion, and Diversity

Objectives of the Study

The purpose of this research was to assess the quality of GenAI-generated word problems for K-12 students. Specifically, the research question was: What is the fit to Common Core State Standards – Mathematics, the mathematics quality, the problem-context role, and the contribution of images in K-12 word problems generated by three popular AI systems?

Conceptual Framework

Use of generative artificial intelligence (GenAI) in mathematics teaching and learning is a relatively recent and growing phenomenon that is particularly pertinent to problem solving (Schorcht et al., 2024). Still in its infancy, GenAI is being used in many ways in mathematics education, including generating tasks and solutions to tasks (Walkington, 2025). In general, word problems created by GenAI models to date have tended to lack variety in problem type and richness (Qin et al., 2024). Of course, different generative AI models, as well as versions within those models, and the specific prompts used influence the quality of mathematical word problems created (Schorcht et al., 2024).

While GenAI shows potential for adapting word problems to student interests and needs that include use of personalized topics and readability levels (Luik et al., 2025; Walkington, 2025), this technology has demonstrated cultural and other biases in its outputs (Walkington, 2025). For example, AI-generated text can misrepresent or minimally include people from different racial/ethnic backgrounds, use gender-stereotyping concepts and language, and homogenize cultural groups (Ho et al., 2025; Rettberg & Wigers, 2025; Shieh et al., 2026). AI-generated images have also been found to include biased representations, as well as physical inaccuracies (York et al., 2024). Biases and limitations result from GenAI's specific training and the information to which it has access. Wei et al. (2025) note, "Trained on extensive internet text data, LLMs often mirror societal biases, stereotypes, and cultural assumptions, thereby influencing decision-making, entrenching stereotypes, and perpetuating inequalities" (p. 7).

Methods

We four researchers specialize in mathematics teaching and learning, two previously at the elementary level and two at the secondary level. Currently in higher education, we have advanced expertise in mathematics education and equity and diversity issues. This background made us especially suited to conduct this research.

Given that teachers have access to using GenAI to create mathematics content, such as word problems (e.g., Cheng, 2024), we aimed to gauge its effectiveness in creating word problems from prompts with the intent to evaluate the mathematics quality and the context ("storied" part) of the problems.

We generated 25 problems as follows:

- Three each using text only for Grades 1, 3, 5, 7, and high school using ChatGPT (GPT-5.2), Gemini (Gemini 3 Flash), and Claude (Sonnet 4.5)
- Two each using text and images for Grades K (oral), 2, 4, 6, and 8 using ChatGPT (GPT-5.2) and Gemini (Gemini 3 Flash; Claude cannot generate useable images)

Example prompts are:

- Write a math word problem between 30 and 40 words that is appropriate for third-grade students according to the Common Core State Standards for Mathematics. Include at least two people. (first group)
- Write a math word problem between 50 and 60 words that is appropriate for eighth-grade students according to the Common Core State Standards for Mathematics. Include at least two people and an associated image. (second group)

We first reviewed the 25 problems for fit to the Common Core State Standards for Mathematics. All but two that fell in a gray/uncertain area were aligned. However, all of the problems were computational and on the lower (more simplistic) end of the spectrum of problems that could fit the intended grade-level standard. We each then reviewed a sheet that summarized bias issues in GenAI before evaluating the generated problems individually, taking notes on our observations about mathematics quality (structure, richness, accuracy, use of key words or extraneous information, and text-to-image alignment, where relevant) and problem context (familiarity, interest, authenticity, readability, writing mechanics, and equity/diversity matters). Finally, we met to discuss our observations and generate findings that all four of us agreed on.

Results

Dominant findings across the problems are as follows:

- Rich problems were lacking (all problems were computational and somewhat simplistic for the intended grade level; unknowns in three-part equations always appeared last).
- Slightly more than half the problems used key words, which appeared mostly at the lower grade levels.
- Most contexts were familiar (e.g., sharing apples, making cookies).
- Most contexts were uninteresting for young people in terms of the "story," and some had a purpose (e.g., saving money for a bicycle) while others did not (e.g., giving another child apples for no articulated reason).

- Most contexts were real-world ("could" happen) but were not very authentic (i.e., they were contrived).
- Much repetition occurred across problems and across models (e.g., 5 problems were about apples, 4 problems used the name Sarah/Sara)
- The images or information in some images either conflicted with the textual problem or were leading/directive.
- All problems used one boy and one girl as the characters.
- Evidence of bias appeared in some problems. Social class issues appeared most often, increasingly so with advancing grade levels. Examples include saving money for a new bicycle and preparing snacks for a field trip. We also identified several incidences of gender bias, as in the boy making a better financial decision than the girl in one problem, and the boy tipping more than the girl in another. Further, in the images, fair-skinned people appeared disproportionately more often than dark-skinned people (16 of 20).
- Confusing language appeared in the text of some problems in terms of syntax, meaning, and specific words that might be unfamiliar, especially to multilingual learners.
- Writing mechanics issues (e.g., spelling, punctuation) only occurred in the images and only for the Gemini model.

Discussion and Conclusions

Generative AI can support the work teachers do in preparing mathematics tasks. Walkington (2025) says, "We need to better ensure GenAI is actually making teachers' lives easier and better supporting their students" (p. 7). However, a number of mathematics and context-related issues occurred in the problems we generated that made them confusing or simplistic. For example, use of key words is a problematic approach to solving and learning how to solve word problems (e.g., Hardy et al., 2025). Issues have also been noted regarding AI-generated problem contexts in that they tend to be inauthentic, which deviates from recommended practice (Walkington et al., 2026). In relation to social concerns, the incidents of bias found in this research must be given serious consideration.

To use AI properly, therefore, teachers must have more, not less, knowledge of mathematics and mathematics pedagogy (National Council of Teachers of Mathematics 2023). Kim et al. (2025) suggest that preservice teachers learn about GenAI use in mathematics teaching and learning from practical and critical standpoints. In essence, both teachers and students must exercise a healthy skepticism toward AI outputs, analyzing it carefully for mathematical errors and bias in the problem contexts generated (National Council of Teachers of Mathematics 2023; Walkington, 2025).

This study examined the effects of a curriculum-aligned Blue-Bot robotics intervention on kindergarteners' spatial reasoning. Eighteen children completed ten weekly robotics sessions integrated with mathematics instruction. An embedded mixed-methods design combined pre–post assessments with a teacher interview. Although overall gains were not statistically significant, students showed improvement in navigation and sequencing skills aligned with robotics tasks. The teacher also reported greater use of spatial language and persistence in problem solving.

Keywords: Early Childhood Education, Technology, Geometry and Spatial Reasoning

Spatial reasoning is central to young children's mathematical development and later success in mathematics and STEM. Yet early geometry often becomes "static," emphasizing shape names and properties while offering fewer opportunities for dynamic spatial thinking involving movement, transformation, perspective taking, and mental rotation (Bruce & Hawes, 2015). Scholars have therefore called for learning environments that support spatial reasoning through object manipulation, representations, and coordinated action in space. Early intervention is especially important because spatial reasoning is not only associated with mathematics achievement but is also malleable and responsive to instruction. For example, Cheng and Mix (2014) found that brief mental-rotation training improved some mathematics outcomes for children ages 6–8. Bruce and Hawes (2015) similarly identify mental rotation as an important but often underdeveloped skill and argue that young children benefit from experiences that make spatial transformations visible and discussable.

Within this broader agenda, educational robotics offers a promising and developmentally appropriate context because it combines movement, planning, spatial language, sequencing, and debugging. Children do not simply use a tool; they engage in embodied problem solving by anticipating movement, testing a plan, observing outcomes, and revising. Francis et al. (2017) argue that robotics tasks support spatial and design thinking because they require attention to direction, orientation, and coordinated action in space. This makes robotics a potentially valuable context for strengthening spatial reasoning. A broader view is provided by Rapti and Sapounidis' review of kindergarten robotics research from 2012 to 2023. Across 59 studies, robotics was commonly examined through outcomes such as critical thinking and problem solving, often using small samples, short interventions, and Bee-Bot or Blue-Bot platforms (Rapti & Sapounidis, 2023). Although the review identified generally positive cognitive outcomes, it also highlighted the need for clearer construct definitions and more systematic research designs.

These concerns extend to how robotics is implemented. Research on early computational thinking emphasizes that instructional design and teacher mediation shape children's engagement and learning (Misirli & Komis, 2023). However, much of the literature has examined short-term, researcher-designed interventions rather than sustained integration into everyday classroom instruction (Rapti & Sapounidis, 2023). Consequently, less is known about how robotics functions within ongoing curricular routines and teachers' pedagogical decision-making. Effective integration requires structured task progression and explicit connections between robot movement and mathematical ideas such as directionality and sequencing (Papadakis & Kalogiannakis, 2020). When Bee-Bot or Blue-Bot activities are embedded within classroom routines, children engage in repeated cycles of prediction, execution, and revision that mirror processes central to spatial reasoning (Misirli & Komis, 2023). Studying robotics in authentic classroom contexts may therefore clarify both instructional processes and domain-specific learning outcomes. A related challenge concerns measurement. Many early childhood robotics studies report broad cognitive or engagement outcomes without clearly defining spatial constructs such as perspective taking, navigation, sequencing, or relative position (Rapti & Sapounidis, 2023). Although validated instruments exist for older students, including the Spatial Reasoning Instrument developed by Ramful et al. (2017), fewer developmentally appropriate measures are available for kindergartners. Adapting validated measures for younger learners may strengthen methodological rigor and clarify how robotics supports specific spatial skills. Addressing these instructional and measurement gaps, the present study examines an instructionally aligned Blue-Bot intervention developed with a kindergarten teacher and coordinated with the existing mathematics curriculum. It focuses on defined spatial reasoning domains and combines quantitative assessment with teacher reflection to examine both learning outcomes and instructional processes. The study addresses two questions: (1) How does participation in an instructionally aligned Blue-Bot robotics intervention influence kindergarten students' spatial reasoning skills? (2) How does the kindergarten teacher perceive and reflect on the integration of robotics alongside her mathematics curriculum?

Method

Participants, Setting, and Procedures

The study included 18 kindergartners, ages 5–6, from a mixed-gender classroom at a university-affiliated early childhood center in the Midwestern United States. Before the intervention, each child completed an individual spatial reasoning assessment. Five pictorial multiple-choice items were adapted from the Spatial Reasoning Instrument (Ramful et al., 2017), selected for alignment with the Blue-Bot lessons, and modified for kindergartners. The assessment measured mental rotation, perspective taking, spatial navigation, and relative position. Each item was scored as correct (1) or incorrect (0), producing a total score from 0 to 5. The intervention consisted of eight weekly, 20-minute lessons integrated into regular classroom activities. Blue-Bot, a transparent floor robot programmed through buttons and fixed stepwise turns, was used to support spatial reasoning, autonomy, and directional understanding. Its design makes command sequences and movements visible for discussion and allows it to function as a digital mathematics manipulative (Berson et al., 2023). Each session included a whole-class introduction, teacher demonstration, work on large grid mats, and reflection. Lessons aligned with the CCSSM and Ohio technology standard K–2.ICT.1.a . Tasks progressed from positional language, single-step commands, and grid navigation to planning, testing, composing, and decomposing multistep paths (Berson et al., 2023). After each session, the researcher and teacher discussed student engagement, challenges, and possible adjustments. After the intervention,

children completed the same assessment using the same scoring procedure, allowing direct comparison of pretest and posttest spatial reasoning scores.

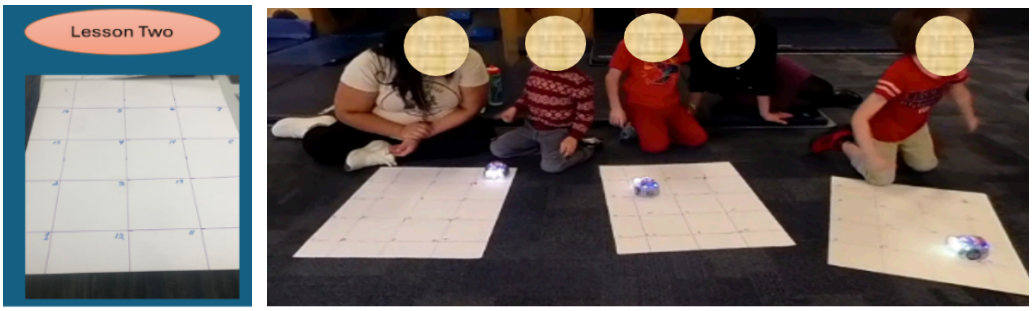

Figure 1: Students Guide the Blue-Bot from 1 to 12 on a Numbered Grid

Data Analysis and Finding

This study used an embedded mixed-methods design, with quantitative pre–post assessment data as the primary strand and a teacher interview used to contextualize the findings (Creswell & Plano Clark, 2011). Given the small sample (N = 18) and limited score range (0–4 after item exclusion), nonparametric tests were used. A Wilcoxon signed-rank test examined changes in total spatial reasoning scores, while McNemar tests examined changes in correct and incorrect responses for individual items representing perspective taking, sequencing, navigation, and relative position. Following the quantitative analysis, the classroom teacher participated in a semi-structured interview (Zazkis & Hazzan, 1999). Questions addressed her confidence using Blue-Bot, observed changes in students' spatial reasoning and directional language, curricular alignment, and possibilities for future integration. The transcript was thematically analyzed for patterns related to learning, engagement, differentiation, and instructional challenges.

A Wilcoxon signed-rank test compared total pretest and posttest scores. Six students improved, five declined, and seven showed no change (see Table 1). The difference was not statistically significant, $Z = -0.98$, $p = .32$, with a small-to-moderate effect size ($r = .23$). These results indicate considerable variation in students' responses to the intervention. To further examine changes across specific spatial reasoning constructs, McNemar tests showed no statistically significant change for any individual item (all $p > .05$). However, descriptive patterns differed across spatial reasoning domains. The strongest improvement occurred on navigation item QD, with eight students improving and four declining. On QC, which involved following a sequence of directions, three students improved and none declined. Perspective taking showed modest improvement, with four students improving and one declining. Relative position showed a less favorable pattern, with three students improving and six declining. Although the quantitative results were not significant, the descriptive trends suggest greater improvement in navigation and sequencing skills, which closely aligned with the Blue-Bot tasks.

Table 1: Changes in Students' Spatial Reasoning Responses from Pretest to Posttest (N=18)

Spatial Reasoning Item	# Students Improved	# Students Declined	# Students No Change	McNemar P Value
QB: Perspective taking	4	1	13	.37
QC: Navigation	3	0	15	.25
QD: Navigation	8	4	6	.38
QE: Position taking	3	6	9	.50
Total	6	5	7	

Note. Improved = change from incorrect at pretest to correct at posttest; Declined = change from correct at pretest to incorrect at posttest; No Change = same response at pretest and posttest.

Teacher reflections supported these patterns. Judy's confidence in using Blue-Bot increased during the intervention, although she initially noted that she was not yet an "expert" and still had logistical questions. As the sessions progressed, she observed stronger directional language, sequencing, and flexibility in route planning. Students increasingly used terms such as "forward," "backward," and "turn," and one child independently revised a path by programming the robot backward when the original plan failed. Judy viewed this as evidence of spatial problem solving rather than memorized movement, consistent with the descriptive gains in navigation and sequencing. She also reported greater engagement and persistence. Students who often became frustrated during mathematics were more willing to revise and try again during Blue-Bot activities. Judy attributed this partly to the hands-on, open-ended nature of the tasks, which created a lower-pressure environment and allowed children to work at different levels of complexity. By the end of the intervention, she viewed Blue-Bot as a flexible instructional tool that could support mathematics and other areas, including literacy, such as coding sight words.

Discussion

This study contributes to research on instructionally aligned robotics for domain-specific spatial reasoning in early childhood. Responding to calls for clearer constructs and stronger alignment between instruction and assessment (Rapti & Sapounidis, 2023), it targeted defined spatial domains within mathematics instruction. Although gains were not significant, descriptive patterns showed greater improvement in navigation and sequencing, skills closely reflected in Blue-Bot activities. Programming required children to predict, execute, evaluate, and revise movements, processes central to spatial reasoning (Misirli & Komis, 2023). Teacher observations of stronger directional language, flexible path revision, and growing confidence further suggest that curriculum-connected robotics may support both spatial reasoning and sustainable classroom integration.

TEACHING AND LEARNING MATHEMATICS IN THE AGE OF AI: PROSPECTS, PRIORITIES, PROCESSES, AND PROBLEMS (4PS)

Shashidhar Belbase
Troy University
sbelbase@troy.edu

Harman Aryal
Stockton University
harman.aryal@stockton.edu

Keywords: Instructional Vision, Technology

The use of Artificial Intelligence (AI) in education, in general, and in mathematics education in particular, is reshaping how the concepts, procedures, and applications are taught and learned. In this poster, we discuss teaching mathematics meaningfully in the age of AI with reference to prospects, priorities, and processes, and problems (4P) associated with using those tools. This study aims at examining the 4Ps of AI augmentation in mathematics education drawing on current research.

The *prospects* of AI in mathematics education extend beyond simple automation toward meaningful augmentation of teaching and learning. AI tools can support mathematical reasoning, generate multiple solution strategies, provide immediate feedback, and personalize instruction based on students' needs and interests. AI-augmented platforms allow both students and teachers for self-paced learning and individualized support. In addition, AI augmented tools can assist teachers in designing lessons, tasks, and formative assessments, contributing to ongoing professional growth (Martinovic & Danesi, 2025). When used thoughtfully, AI has the potential to deepen conceptual understanding and encourage reflective thinking. The research community in PME-NA are also focusing on the potentials and issues related to AI in mathematics education (Belbase et al., 2025; Zhu et al., 2025; Zhuang et al., 2025), the research interest in this area is growing over the last few years.

At the same time, clear *priorities* must guide the integration of AI tools in the teaching and learning of mathematics. Conceptual understanding and mathematical reasoning should always remain the central focus of instructional practices. Teachers should spend considerate amount of time discussing the mathematical concepts critically, verifying the knowledge sources, and refining AI-generated responses rather than simply accepting them as is. Ethical use, academic integrity, and data privacy are essential considerations in AI-supported environments. Effective implementation requires thoughtful scaffolding and teacher preparation to ensure that AI enhances human interaction rather than replaces it (Noakes et al., 2024; Richard et al., 2022). The AI-augmented tools can help mathematics educators and teachers to plan what to teach and what is not needed to teach because AI can help students solve those problems. Hence, the new priorities of teaching mathematics are in the horizon that mathematics education community needs to identify, explore, and priorities so that mathematics can be interesting, teaching of this subject can be rewarding, and use of AI in this direction can be an added value in TPACK and STEM education.

The *processes* of mathematics teaching are also shifting very rapidly. AI-augmented instruction can promote learning-by-teaching models, tiered task design, and structured peer collaboration. Human–machine–human interaction cycles encourage students to explore ideas, evaluate AI outputs, and strengthen their reasoning. Teachers can use AI-generated insights to identify patterns in student thinking and adjust instruction accordingly (Noakes et al., 2024; Ramadhani & Ramadani, 2025). In this way, classroom learning can shift from simply seeking answers to evaluating and reasoning about solutions. Hence, AI-augmented tools may shift the process of teaching and learning mathematics by shifting its role to support both teachers and learners through the processes of idiosyncratic questioning, receiving feedback, and reposing new questions.

However, several emerging *problems* must be addressed as we progress toward over reliance on the AI tools. AI systems may occasionally generate inaccurate or misleading outputs, particularly in mathematics, that appear convincing. Overreliance on AI may reduce perseverance and engagement with high-cognitive-demand mathematical tasks. Concerns regarding equity of access, privacy, and reduced human-to-human interaction also remain significant. Therefore, while AI offers strong promise, mathematics educators must adopt a critical and balanced approach to ensure meaningful, ethical, and equitable learning experiences (Richard et al., 2022).

In conclusion, AI can support mathematical reasoning, personalization in learning, and reflective practices. However, its impact depends on thoughtful and ethical integration into classroom teaching through policies and classroom practices to ensure that AI enhances conceptual understanding rather than replacing critical thinking. A balanced approach can help sustain meaningful, equitable, and high-quality mathematics education in the age of AI.

BRIDGING REPRESENTATIONS: INTEGRATING COMPUTATIONAL ACTIVITIES INTO AN INTRODUCTORY LINEAR ALGEBRA COURSE

Sarah D. Castle
University of Idaho
scastle@uidaho.edu

Annelise W. Nielsen
University of Idaho
annelise@uidaho.edu

Keywords: Computational Thinking, Coding and Computing, Undergraduate Education

Although computation plays a growing important role in modern STEM practices and research, current research and pedagogy has not yet fully leveraged how computation can support students' mathematical thinking rather than simply providing technical skills (Lockwood & Mørken, 2021). When computation is added to undergraduate mathematics courses, it is often disconnected from course goals or treated as an add-on, which misses its potential, especially given that many students experience coding as creative and exploratory while viewing mathematics as comparatively rigid (Isomöttönen et al., 2020, Selbach-Allen et al., 2020). This work focuses on developing a structure for integrating computation into a standard linear algebra course to support conceptual learning and foster creative engagement with mathematical ideas.

In developing this course, we started by establishing the foundational pieces needed for a full implementation in Fall 2026. We gathered all existing linear algebra syllabi and course materials from the past five years to identify departmental topic priorities and key learning objectives. These were compared to the objectives in our previously developed computational modules (Castle, 2023a) to ensure alignment and content coverage. Because the modules were designed from the perspective of computation as pedagogy, we mapped all objectives across the semester and identified where conceptual scaffolding or coding support was needed. This work led to the development of paired mathematical and computational learning objectives for each major topic. This was an explicit choice to ensure computation was positioned as a pedagogical tool for broadening the forms of representation and exploration available to students. The mapping process also clarified where departmental expectations naturally supported computational approaches and where additional support structures would be needed to prepare students.

These paired objectives guided our development of a recurring learning cycle organized around the big mathematical ideas in the course. Each cycle begins with tasks that introduce a core concept and allow for computational exploration. Students then work in computational modules to test examples, visualize structures, explore patterns, and refine initial predictions. Post-module tasks help students articulate what the computational work revealed, and formalization tasks then connect that exploratory work back to established linear algebra structures and definitions. The design draws on theoretical perspectives that position computation as a mediating tool for mathematical creativity and is informed by prior pilot work showing that prediction, experimentation, and reflection in computational environments can reshape how students view mathematics and their relationship with it (Castle, 2023b).

This work offers a structured, intentional model for integrating computation into undergraduate linear algebra while meeting departmental and college learning standards. Through our framework, objectives, and examples, we aim to contribute to ongoing conversations about how computation can be meaningfully integrated into undergraduate mathematics in ways that support conceptual understanding, broaden students' views of the discipline, and create space for more creative mathematical activity in STEM courses.

Keywords: Technology, Problem-Based Learning, Rational Numbers & Proportional Reasoning

As AI-driven technologies become more common in mathematics classrooms (e.g., Borba et al., 2024), understanding how they support development of deep mathematical understanding in collaborative classroom settings remains limited (Hwang & Tu, 2021; Mohamed et al., 2022). Most research and classroom use of AI in mathematics focuses on either generative tools like ChatGPT, which provide explanations but can be unreliable or misleading, or intelligent tutoring systems, which offer individualized and adaptive assistance but are rarely designed for collaborative classroom learning (Wardat et al., 2023; Engelbrecht & Borba, 2023). Therefore, there is a need for AI tools that support inquiry-oriented, problem-based mathematics, helping teachers gain real-time, actionable insights into students' collaborative learning over time.

Our project leverages a digital collaborative platform with an embedded middle grades problem-based mathematics curriculum, where students document and share their reasoning through different mathematical representations and tools (e.g., Edson, 2024; Edson & Phillips, 2021) Teachers and researchers tag student work using a proportional reasoning rubric, creating a curated dataset that will train AI models to interpret students' reasoning (Edson et al., 2024). As teachers tag work, the platform's analytics immediately organize, sort, and filter student contributions, providing real-time insights that help teachers monitor reasoning patterns, facilitate discussions, and reflect on instruction. By integrating multimodal student work, collaborative documentation, and teacher-generated tagging, the platform provides a classroom-embedded approach for accessing actionable insights into students' mathematical thinking.

This poster presents design principles, guidelines derived from iterative design-based research (e.g., Barab & Squire, 2004), that make student reasoning visible and actionable for both students and teachers. The platform supports collaborative problem-solving, enabling learners to build on each other's work while preserving individual strategies. Teacher-facing analytics provide real-time, actionable insights through sorting, filtering, and comparison of student contributions to guide instruction and discussion. Multimodal representations (text, equations, tables, graphs, and drawings) capture diverse approaches and support meaningful analysis. Together, these principles illustrate how tools can integrate student-centered learning, collaboration, and AI-powered analytics to enhance classroom practice.

Keywords: Technology, Geometry and Spatial Reasoning, Research Methods

Over three decades, research on dynamic geometry environments (DGEs) has expanded across geometry learning, reasoning, pedagogy, and student engagement. Despite this growth, there has been limited systematic synthesis of the thematic directions organizing empirical DGE scholarship. This study presents a systematic review of 233 peer-reviewed empirical journal articles published between 1991 and 2023 to identify the major thematic trajectories in DGE research. The guiding research question is: What research themes have emerged across three decades of empirical research on dynamic geometry environments?

Following PRISMA screening procedures, this study employed a hybrid structural topic modeling (STM) approach combining R-based STM with AI-assisted topic generation using Copilot and ChatGPT (Chen et al., 2020; Farrell, 2016; Roberts et al., 2014). Candidate topic structures generated using Copilot and ChatGPT informed, but did not determine, a researcher-led deductive thematic analysis. Researchers completed all final coding and theme refinement (Braun & Clarke, 2006; Fereday & Muir-Cochrane, 2006).

Five major themes emerged: Geometry Content and Conceptual Understanding, Cognitive and Learning Processes, Individual Differences and Accessibility, Pedagogical Implementation, and Student Outcomes and Engagement. Geometry Content and Conceptual Understanding was the dominant research focus (36.9%), whereas Individual Differences and Accessibility remained comparatively underrepresented (9.4%). The review also revealed a longitudinal shift from early investigations emphasizing geometric reasoning, dragging, and proof toward increasing attention to pedagogy, classroom implementation, learner diversity, and engagement.

The resulting thematic map reveals how DGE scholarship has evolved alongside changes in educational technology and instructional priorities. This synthesis provides a framework for positioning future studies within established and emerging areas of DGE research.

LEARNING EXPONENTIAL FUNCTIONS WITH IMMERISVE VIRTUAL REALITY

Brent E. Jackson	Amber Beliakoff	Andrew Grillo-Hill
WestEd	WestEd	WestEd
bjackso@wested.org	abeliak@wested.org	agrillo@wested.org

Keywords: Exponential Functions, Educational Technology, Immersive Virtual Reality

Mathematics teachers and students alike want the ideas in their classrooms to be meaningful and relevant. To do so, many teachers and curricula craft real-world contexts for students to explore grade-level mathematics (e.g., Leonard et al., 2010). Educational technologies, such as immersive virtual reality (IVR) have the potential to support students in seeing how the mathematics they are studying applies to real-world situations. PrismsVR is one IVR supplemental mathematics curriculum that has the potential to support students seeing mathematics as interesting and worthwhile, by taking students on virtual field trips to explore real-world phenomena, which are then mathematized. In this poster, we investigate the impact of one of PrismVR's modules, exponential functions, on students' mathematics achievement.

The affordances and outcomes of IVR are identified in the Cognitive-Affective Model of Immersive Learning (Makransky & Petersen, 2021). In this model, *presence* and *agency* are two key technological affordances which influence the affective and cognitive factors (e.g., interest, motivation, self-efficacy) that contribute to learning. *Presence* is the feeling of "being there" (Ijsselsteijn & Riva, n.d.). IVR hardware and software can provide users an "illusion of being physically present in a different world or setting" (Engelbrecht & Borba, 2024, p. 287). *Agency* within the context of IVR is the degree to which users can control their own actions within the virtual world.

We designed a randomized controlled trial to measure the impact of the PrismVR's exponential functions module on students' mathematics achievement. We recruited 26 teachers teaching Algebra 1 (or its equivalent) and their students (262 treatment and 252 control students) to participate in the study. Teachers were randomly assigned to the treatment or comparison group using blocked randomization. Treatment and control teachers taught their courses in their business-as-usual manner; however, the treatment condition also experienced a PrismsVR module as an introduction to three units of study: linear functions, systems of linear functions, and exponential functions. We used a 27-question researcher-designed pre- and post-assessment to measure mathematics achievement with regard to exponential functions (Cronbach's $\alpha = 0.83$).

We analyzed students' learning of exponential functions by evaluating pre-test differences between the treatment and control groups to determine that, in fact, there were low baseline differences (–0.02 standard deviations). We then performed a 2-level mixed effects linear regression to determine if differences between treatment and control were present at posttest. The model accounted for nesting of students within teachers (a random effect), and included fixed effects for condition, and pre-test. The results revealed a significant difference in the posttest assessment adjusted means between the treatment and control groups, showing a 2.94-point increase (effect size, $g = 0.53$) between treatment and control groups.

HUMAN-IN-THE-LOOP AI IN MATHEMATICS EDUCATION: A CONCEPTUAL FRAMEWORK FOR INTEGRATING AI TOOLS WITH TEACHER EXPERTISE

Derrick Kumi
Louisiana State University
dkumi1@lsu.edu

Thomas E. Ricks
Louisiana State University
tomricks@lsu.edu

Keywords: Instructional Activities and Practices; Teacher Knowledge; Classroom Discourse; Equity, Inclusion, and Diversity

This poster presents a conceptual framework for integrating artificial intelligence (AI) tools into mathematics teaching in ways that strengthen, rather than replace, teacher expertise. The purpose is to synthesize recent literature on AI in mathematics education (Awang et al., 2025; Grassini, 2023; Nguyen & Pham, 2025; Opesemowo & Ndlovu, 2024; Yavich, 2025) and translate it into a practical, classroom-oriented model for instructional decision-making, formative feedback, and equitable implementation. The following questions guide the study: (1) Where does AI add meaningful value in mathematics teaching and learning? (2) What aspects of mathematics teaching must remain teacher-led to preserve sensemaking, justification, and sound pedagogical judgment? (3) What classroom routines and guardrails can support responsible and equitable use of AI tools in mathematics classrooms?

Theoretical Framework

This project is guided by a human-in-the-loop perspective (Mosqueira-Rey et al., 2023; Munro, 2021) on AI integration in mathematics education, which treats AI as a support tool whose outputs require human interpretation, verification, and pedagogical decision-making. Rather than positioning AI as a replacement for teaching, this perspective emphasizes the central role of teacher expertise in evaluating mathematical validity, interpreting student thinking, and designing responsive instruction (Datta et al., 2022).

Methods

This project uses an integrative review methodology (Whittemore & Knafl, 2005) to synthesize recent scholarship and policy-oriented literature on AI in education and mathematics education. The review focused on literature published between 2019 and 2026 to ensure the study captures both pre-generative AI developments and the rapid expansion of generative AI tools in mathematics education. Sources were identified through high-quality, reliable databases: Scopus, ERIC, EBSCOhost, and professional organization sources such as NCTM (2024). Search terms included AI-related terms, mathematics education terms, and framework-related terms. The criteria for inclusion were based on whether the source addressed AI use in education or mathematics education and contributed to understanding teacher decision-making. The exclusion process removed sources that were not peer-reviewed journal articles, non-English, or technical AI sources unrelated to the study. After screening 843 articles, the selected literature was thoroughly analyzed by identifying common AI affordances, recurring risks and constraints, and instances requiring teacher judgment. These patterns were then synthesized into a human-in-the-loop framework for classroom use in mathematics.

Results and Implications

The integrative review suggests that AI tools can contribute to mathematics instruction in four main ways: generating multiple explanations, identifying possible misconceptions in student

work, offering alternative representations, and helping teachers scale formative feedback. However, the framework positions these AI contributions as provisional rather than authoritative. In other words, every AI output needs to be reviewed by a teacher to ensure mathematical accuracy, conceptual depth, proper representation, and alignment with instructional objectives.

The mathematics-specific contribution is pinpointing crucial "handoff points" where teacher expertise is essential: assessing the validity of solutions generated by AI, interpreting students' unconventional strategies, determining if a representation clarifies or obscures mathematical structure, and guiding students toward justification instead of just answers. Additionally, the framework considers equity as a key design element. For instance, when AI creates contextualized math problems, teachers need to evaluate whether the context, language complexity, assumptions, and accessibility promote inclusive participation and avoid reinforcing biases or increasing disparities.

MATHBUDDY: DEVELOPING AND PILOTING AN AI COMPANION AGENT FOR MATHEMATICAL WORD PROBLEM SOLVING

Haoru Li
Arizona State University
haoruli@asu.edu

Biyao Liang
The University of Hong Kong
biyao@hku.hk

Rui Liu
The University of Hong Kong
ruiliu@connect.hku.hk

Keywords: Technology, Problem-Solving, Communication

With the rapid development of generative AI, an increasing number of students are using AI technologies to learn mathematics. This trend appears promising, as many pedagogical agents are virtual characters designed to enhance teaching and learning (Siegle et al., 2023). However, how to integrate AI into core subject learning in purposeful, pedagogy-aligned ways and how to cultivate effective human–AI collaboration remains in need of systematic investigation (OECD, 2025; UNESCO, 2024). Moreover, research on student–student interaction shows that conceptual growth is amplified when learners actively interpret their peers' thinking, interrogating, adopting, and building on alternative perspectives of others (Rasmussen et al., 2020; Webb, 2023), yet few pedagogical agent designs foster such engagement with the agents' "thinking." To address these gaps, this poster proposes *MathBuddy*, an AI companion for mathematical word problem solving, and analyzes its piloting with students in Hong Kong.

Research Design

Closely aligned with the Hong Kong local curriculum, MathBuddy is powered by the Grok 4.3 model via API services and operates as a self-hosted chatbot web application. It engages students in meaningful dialogues by harmonizing the dual features of collaborative problem-solving agents and teachable agents, collaborating with students to jointly solve mathematical problems and prompting students to explain mathematical ideas. To ensure MathBuddy's conversational moves both mathematically rigorous and pedagogically powerful, we employ prompt engineering informed by established practices in teacher talk moves (Chen et al., 2020), Socratic teaching (Zhang et al., 2024), and peer discussion (Rasmussen et al., 2020). In addition, the agent's knowledge base comprises (1) a summary of key concepts, (2) a bank of mathematical problems situated in authentic, cultural-relevant contexts, and (3) detailed mathematical and pedagogical descriptions of each problem.

We conducted a pilot study with Hong Kong junior secondary students ($n = 45$) to examine the interaction dynamics and pedagogical potential of MathBuddy. Each participant engaged in an individual 30-minute problem-solving session with MathBuddy, followed by a one-on-one stimulated recall interview lasting 30–40 minutes with a researcher, who presented selected chatlogs and invited the student to reflect on their thinking and interpretations of MathBuddy's prompts. Qualitative thematic analysis is used to analyze the chatlogs and transcripts to identify students' problem-solving strategies and interaction patterns, while video data is used to triangulate findings and capture non-verbal cues.

Findings and Implications

The study is expected to yield interaction patterns between students and MathBuddy, including the characteristics of prompts that students perceive as valuable, as well as the ways in which these prompts influence students' reasoning trajectories and mathematical understandings. These findings will generate empirically informed design principles for curriculum-aligned AI companion agents that support collaborative problem-solving in mathematics.

STUDENT-CREATED MATHEMATICS WIKIBOOK: BEYOND TECHNICAL ACCESSIBILITY

Webster Wong
University of Georgia
whw99124@uga.edu

Selen Çaylı
University of Georgia
selen.cayli@uga.edu

Wikibooks sit in the intersection of open textbook and student authorship, which are two open education practices that have received some attention from researchers (Galarza & Perry, 2017; Hilton, 2020; Neill, 2024; Wong & Leatham, 2026). Contribution from diverse students in this process of knowledge creation could further increase the value of the learning resource being created. Our goal is to explore the nature of student contribution in the Wikibooks platform where technical barriers are minimal. Our research question is the following: How do student contribute to a Wikibook? More specifically, we are interested in understanding the ways different student authors engage in the development of a Wikibook as they contribute to it.

Methods

The open textbook we examined is "High School Mathematics Extensions" (HSME, 2025), which is one of the three featured books in mathematics on Wikibooks. The listed authors of this Wikibook identified themselves as students. For this study, we selected the Discussion Pages associated with the *Main Page* and the *Primes and Modular Arithmetic Page* (Primes Page) of the HSME book. There was a total of 80 comments in the two Discussion Pages. Garrison et al. (2001) introduced a framework for practical inquiry to understand the level of cognitive presence in computer-mediated communication. We adapted this practical inquiry framework, which provided four phases of inquiry, to assess the cognitive presence of the contributors of HSME to see how they make meaning through conversations in the Discussion (see Wong & Çaylı, 2026).

Results

Overall, we have found that while the primary author showed a dominance in the Resolution Phase, Wikibook allowed different authors in different positions a chance of contributing. As seen in our analysis, all 15 but two of the comments in the Resolution Phase was made by the primary author. This shows that the primary made most of the decisions around this Wikibook. This also shows that the non-author contributors tend to not make decisions around this Wikibook. On the other hand, the number of comments were comparatively high in Triggering and Exploration. Moreover, the number of distinct contributors in the Triggering and Exploration Phases was much higher compared to Resolution. In other words, many contributors participated in the development of this Wikibook by making inquiries and brainstorming, and not as much in creating ideas to resolve issues. This might indicate that this Wikibook allowed different authors in different positions a chance of contributing.

Conclusion

The Wikibooks platform is considered to have a high level of openness regarding its technical aspects (Hilton et al., 2010). Although this high level of technical accessibility allowed all contributors to contribute in any of the four phases, our analysis showed an uneven distribution of higher-level cognitive presence among the contributors. Even though everyone had the same technical access to the Wikibook, there is something non-technical that could have played a role is this domination.

Keywords: Algebra and Algebraic Thinking, Number Concepts and Operations

Algebra is regarded as the gateway subject into advanced mathematics and STEM pathways (Cai & Knuth, 2005; National Mathematics Advisory Panel, 2008). Yet, many students encounter algebra in tandem with negative numbers in middle school, a combination that can intensify conceptual difficulty (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). Despite longstanding efforts to strengthen algebra readiness in the early elementary grades (e.g., Knuth et al., 2016), students continue to struggle with negative numbers and the multiple meanings of the minus sign (Vlassis, 2004, 2008). These challenges are further compounded by over-generalizations of whole number "rules," such as subtraction makes numbers smaller (see, e.g., Karp et al., 2014). To address this need for early understanding of negative numbers, we are designing six board and card games that support elementary students in exploring integer principles in meaningful and motivating ways (see, e.g., Dickman & Bofferding, 2016–2017; Wessman-Enzinger & Bofferding, 2014).

This poster focuses on Opposite Odyssey, the first game in a design sequence, which targets barriers related to integer order and value. Our game design work follows Cardinot et al.'s (2022) five-step game development framework and highlights three foundational integer principles: the minus sign can designate negative or opposite (Vlassis, 2004), numbers exist on both sides of zero and are ordered relative to zero, and integers involve both linear value and absolute value (Ball, 1993; Bofferding, 2014). These principles are embedded directly into the game's mechanics rather than treated as supplemental explanations. Two to four players construct signed two-digit numbers using digit and sign cards and place tokens on a shared number line. A randomly selected target number (100, 0, −100) requires players to reason about "closeness" in ways that make distinctions between absolute and linear value (Wessman-Enzinger & Bofferding, 2018). Action cards (e.g., switching the digit order, creating opposites) introduce strategic decision-making that encourages comparison, discussion, and justification while maintaining the playful nature of the game. Iterative prototyping and playtesting with advisory board members, educators, and 2nd–4th grade students informed revisions to the game. Data sources include usability notes, focus group interviews, and observations of students' behavioral, emotional, and cognitive engagement.

This new working group aims to reimagine current standards for early childhood mathematics teacher preparation. Often subsumed into elementary teacher preparation or mathematics teacher preparation at large, we believe that early childhood mathematics teacher preparation requires unique pedagogical, developmental, and mathematical expertise and therefore warrants focused recommendations. Together, we will: 1) identify skills that early childhood teachers need to support students' mathematical development; 2) gather information about existing standards and recommendations; 3) analyze that information for similarities, differences, gaps, and aspects to be elevated; 4) begin collaboratively revising recommendations; 5) develop a plan for drafting and disseminating updated recommendations; and 6) establish a shared resource repository to support early childhood math teacher educators.

Keywords: Early Childhood Education, Preservice Teacher Education, Teacher Educators, Standards

Early childhood mathematics education (ECME) is a distinct and evolving niche within the broader field of teacher education (Parks & Wager, 2015; Whyte et al., 2018). Unlike other early childhood preservice teacher (PST) coursework and teaching experiences, ECME is murky, with varying emphasis on Developmentally Appropriate Practices (DAP) (National Association for the Education of Young Children [NAEYC], 2020) in methods courses due to differing certification standards (e.g., early childhood teachers in Illinois and New York are certified to teach through second grade whereas they are certified through sixth grade in Texas), shifting institutional or state priorities (e.g., changes in mathematics coursework requirements to accommodate additional literacy courses in teacher preparation programs), and blurred disciplinary boundaries (e.g., mathematics content is sometimes embedded within integrated science, technology, engineering, and mathematics (STEM) methods courses rather than taught as a standalone mathematics methods course; Sarama & Clements, 2009). Together, this means that early childhood teachers across the United States experience significant variety in their preparation for teaching mathematics.

Theoretical and Conceptual Background

Taking a sociocultural perspective on learning (Lave & Wenger, 1991; Vygotsky, 1978), we understand that teaching and learning are deeply interconnected, not only with one another but also with the identities of teachers and students and the broader school and societal contexts in which they are situated. Given the unique nature of early childhood mathematics education,

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

teaching early childhood mathematics requires specialized skills and knowledge. Preservice early childhood teachers need to develop a deep understanding of foundational mathematics concepts so that they are prepared to enter the classroom (Association of Mathematics Teacher Educators [AMTE], 2017). This includes understanding how young children develop number sense, spatial reasoning, and problem-solving skills. Preservice early childhood teachers also need experience with and knowledge of developmentally appropriate practices to support mathematical growth. Another skill preservice early childhood teachers need for teaching mathematics is responsiveness; skilled teachers make responsive, pedagogical decisions to support their students both before, during, and after instruction (Robertson et al., 2015). This may involve considering what students know and who students are to ensure that lessons are culturally sustaining (Paris, 2012), increasing or decreasing challenge, adding relevant examples, or explaining concepts in different ways to ensure that their students achieve the intended learning outcomes (e.g., Cirillo et al., 2009; Dietiker et al., 2018). Finally, collaborating with families is also key to early childhood mathematics education. Preservice teachers need to learn to not only share what learning is happening in the classroom with students' families but also engage families in meaningful ways such that caregivers become true partners in children's early math development (NAEYC & National Council of Teachers of Mathematics [NCTM], 2010).

Working Group Session Goals and Plans

This new working group will provide a collaborative space to critically reflect on the current state of early childhood math teacher preparation and what is needed to strengthen the field. Our group builds on a four-year, ongoing community circle through the Association of Mathematics Teacher Educators. During this time, our group has reported on various topics applicable to early childhood math teacher educators (ECMTEs), such as: the landscape of early childhood mathematics teacher prep, integrating play-based learning in early childhood mathematics methods courses, adapting curricular resources in early childhood mathematics, and pathways for professional development of ECMTEs.

Over the course of the three days, our team will lead participants in reimagining recommendations and core pedagogical practices for supporting preservice early childhood teachers in developing as mathematics educators. The goals of the working group across the three 90-minute sessions are as follows:

- Day 1: Identify a collection of skills that beginning early childhood teachers need to support students' mathematical development. Gather information about standards and recommendations for the preparation of early childhood mathematics teachers that exist across state and national contexts and from various professional organizations.
- Day 2: Analyze the information gathered on Day 1 for similarities, differences, gaps, and aspects to be elevated.
- Day 3: Begin collaboratively revising guidelines and recommendations for professional organizations and develop a structured plan for drafting and disseminating updated recommendations. Establish a shared resource repository to support ECMTEs in implementing the revised recommendations.

As a result of this new working group, we will establish a plan for continued action that will support us in developing recommendations for early childhood mathematics teacher preparation that better echo expertise from both mathematics and early childhood educators.

PRODUCTIVE STRUGGLE EVIDENCE: STRUGGLE, PROGRESS, CULTURE AND TECHNOLOGY

Monica Anthony
Georgia Gwinnett College
manthony5@ggc.edu

Mary Ramos-Duke
Boise State University
mramosduke@boisestate.edu

Nitchada Kamlue
Western Michigan University
Nitchada.kamlue@wmich.edu

In its third year, this working group continues to develop a shared understanding of productive struggle by engaging participants in examining evidence of mathematical struggle in various contexts. In the first session, participants will discuss evidence of mathematical struggle and progress. In the second session, participants will add another layer of evidence by exploring how noticing students' public productive struggle connects to a sense of belonging, intersecting with culture and language differences. In the third session, participants will discuss how technology and tools impact students' access to mathematically productive struggle.

Keywords: Cognition, Instructional Activities and Practices, Research Methods, Teacher Educators

The Productive Struggle Working Group brings together mathematics educators, researchers, and teacher educators to examine existing constructs of productive struggle and to develop new, critical conceptualizations of struggle that connect cognition to affective components of teaching and learning mathematics. The first iteration of this working group sought to develop a shared, consensus definition of productive struggle to address the variety of definitions used by researchers (Kamlue & Van Zoest, 2024). In our second year, we added to our conceptions of productive struggle by incorporating teacher productive struggle (Baker et al., 2024) and the rights of the learner (Kalinec-Craig, 2017). As a group, we workshopped a theoretical framework that described how intentional and routine engagement in productive struggle can help to foster and reinforce students' sense of belonging in mathematics.

For PME-NA 48, we will continue our iterative design cycle of reviewing, revisiting, and refining our definitions and frameworks. Our planned sessions invite participants to dive deeper into the classroom interactions that foster (or hinder) mathematical struggle and a sense of belonging, as we continue to explore the questions and wonderings raised by participants.

Theoretical Background

Our conceptions of productive struggle are informed by Warshauer (2015) and Jarry-Shore and Richardson (2024), which are rooted in Hiebert and Grouws' (2007) definition of productive struggle and Kapur's (2009) definition of productive failure. Both the National Council of Teachers of Mathematics (NCTM, 2014) and the Association of Mathematics Teacher Educators (AMTE, 2017) identify providing students with opportunities to engage in productive struggle as a key component of effective mathematics teaching and learning. We extend the positions of NCTM and AMTE to assert that routine engagement in productive struggle can empower learners and cultivate a sense of belonging in mathematics. In turn, students' growing sense of belonging is imperative for students to take risks, make mistakes, and develop the vulnerability needed to struggle with mathematics (Buli, 2025; San Giovanni et al., 2020). Together, productive struggle and a sense of belonging reinforce students' mathematical authority, agency, and identity (Ramos-Duke & Anthony, 2026).

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Structure of the Sessions

Each session will focus on evidence of productive struggle by: (1) exploring evidence of mathematical struggle and mathematical progress; (2) connecting that evidence to culture, language, and a sense of belonging; and (3) identifying instructional tools and technology that support the cultivation of productive struggle.

Session 1: Evidence of Mathematical Struggle and Progress

The first session will introduce participants to two types of evidence: (a) evidence of mathematical struggle and (b) evidence of mathematical progress. *Evidence of Mathematical Struggle* is defined as "a verbal, written, or physical expression of tension—mathematical confusion, uncertainty, frustration or unsettledness" (Kamlue &Van Zoest, 2026). *Evidence of Mathematical Progress* is exhibited by "learners' verbal or written expressions indicating that a learner has made sense of something mathematical, regardless of whether that something was the task, the underlying mathematics of an artifact, or another mathematical idea introduced to the discussion" (Kamlue & Van Zoest, 2026). Participants will be presented with a case study of a learner who showcases both types of evidence. We invite participants to wonder, when you walk into a classroom (K-16), how would you determine whether someone is experiencing productive struggle or mathematical progress?

Session 2: Noticing: Culture, Language, Belonging, and Productive Struggle

In this session, we will invite participants to consider productive struggle as a social construct that supports a sense of belonging in mathematics (CASEL, 2022; Jarry-Shore & Richardson, 2024; Sherin et al., 2011). A sense of belonging is the feeling of being a member or of fitting into a group or community (CASEL, 2022), and it is imperative for students to take risks, make mistakes, and be vulnerable enough to struggle through solutions (Buli, 2025; San Giovanni et al., 2020). Therefore, we consider the need for teacher noticing of students' struggle through a cultural and linguistic lens not only to "observe, realize and attend to" (Sherin et al., 2011, p. 280) their struggle but also to highlight, celebrate, and create a culture of collective struggle. Evidence of struggle and progress resides in the students' own language. Students walk into a mathematics classroom with their own phrases and feelings about struggle and progress (Moll et al., 2006; Yosso, 2005). Thus, we will invite participants to explore: How might a teacher use noticing to promote productive struggle in linguistically and culturally diverse classrooms? How do we know students are comfortable with productive struggle? How might this practice support a sense of belonging in the whole group and in small groups? How might the components of mathematical identity impact productive struggle and a sense of belonging?

Session 3: Noticing: Technology, Tools, and Productive Struggle

Our final session invites participants to consider the influence of instructional tools and technology on students' opportunities to engage in mathematically productive struggle. The National Council of Teachers of Mathematics (NCTM) states that technology should "elicit and use evidence of student thinking to communicate positive messages about learners' mathematical identities" (NCTM, 2023). Teachers should intentionally use technology tools that promote sense-making and foster classroom discourse. However, while NCTM calls for teachers to support productive struggle in learning mathematics (NCTM, 2014), none of the position statements on technology or AI describe how teachers can use technology to support mathematical struggle (NCTM, 2023; 2024). We invite participants to consider: How might common classroom tools and activities impact students' opportunities to engage in productive struggle? How does the use of technology influence or hinder students' sense of belonging? How do we prepare mathematics educators to leverage these tools in meaningful ways?

WORKING GROUP REPORT: EMPOWERING STUDENTS WITH PRODUCTIVE STRUGGLE WORKING GROUP

Monica Anthony
Georgia Gwinnett College
manthony5@ggc.edu

Mary Ramos-Duke
Boise State University
mramosduke@boisestate.edu

Tegan Nusser
Bradley University
tnusser@bradley.edu

At PME-NA 47, the Productive Struggle in Mathematics Education Research, Teaching, and Learning Working Group met for its second year, this time focusing explicitly on the link between productive struggle and students' sense of belonging. During our sessions we explored how routinely providing opportunities for productive struggle can lead to a sense of belonging in mathematics and developing tools and practices for supporting teachers in the creation and maintenance of productive struggle. The group has sustained a dedicated group of members who meet regularly online since the end of PME-NA 2024. In this report, we summarize the history of the working group, describe our progress and our plans for the future of the working group.

Keywords: Research Methods, Instructional Activities and Practices, Teacher Educators, Preservice Teacher Education

Our PME-NA working group brings together mathematics education researchers and teacher educators to examine conceptualizations of productive struggle and explore how we might study students' experiences of productive struggle. While mathematics education research has operationalized varying definitions of *productive struggle* (Kamlue & Van Zoest, 2024), our working group utilizes the conceptualizations established by Warshauer (2015) and Jarry-Shore and Richardson (2024), which are rooted in Hiebert and Grouws' (2007) definition of productive struggle. Hiebert and Grouws (2007) describe productive struggle as "students expend[ing] effort to make sense of mathematics," grappling with tasks that are within their reach (p. 387).

In this report, we summarize the outcome of our sessions at PME-NA 47 in State College, PA. Then, we describe the ongoing progress and the long-term plans for the working group. During our time together at PME-NA 47, we continued to build on the working group's shared, consensus definition of productive struggle, by examining established theoretical frameworks and developing our own frameworks. We also explored how teacher productive struggle (Baker et al., 2024) connects to definitions and conceptualizations of student productive struggle. Finally, we invited participants to humanize struggle through the lenses of sense of belonging and the rights of the learner.

Summary of 2025 Conference Activities

Session One

Our goal for the first session was to develop a continuum of student struggle. The intent was to integrate existing research and working group discussions into a diagram that captured the range of student experiences from unproductive struggle to productive struggle, documenting the student behaviors and emotions indicative at each stage.

We began the session by sharing the consensus definitions of *struggle* and *productive struggle* generated by the PME-NA 46 working group (Table 1). All but one participant were attending the working group sessions for the first time and were not familiar with the different conceptions of productive struggle.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Table 1: PME-NA 46 Participant Responses

What is Struggle?	What is Productive Struggle?
Struggle can appear in non-verbal ways in addition to what is said.	Productive struggle is going somewhere; leading to the correct solution eventually *or* leading to something mathematical along the way.
Struggle ends in failure and a feeling that the efforts are going nowhere.	Productive struggle is from the students' perspective/view.
Struggle is not making headway but giving up.	Productive struggle requires a movement towards either a goal or a greater understanding.
Struggle is not knowing where to go.	Struggle is productive if there is progress made (or engagement is continued) toward resolving a task.

We spent the majority of the session examining formal and informal frameworks of productive struggle (Jarry-Shore & Richardson, 2024; Murdoch et al., 2020; Sengupta-Irving & Agarwal, 2017; Warshauer et al., 2021). As participants scrutinized each framework, we asked them to consider the following:

1. Does the diagram help to illuminate what productive struggle is?
2. Does the diagram help us to identify types of struggle?
3. Is the diagram useful for the work of teacher educators and in-service teachers?

We then invited participants to consider how they might expand, improve, or combine the various frameworks and diagrams. Facilitators charted these conversations on the board (see Figure 1).

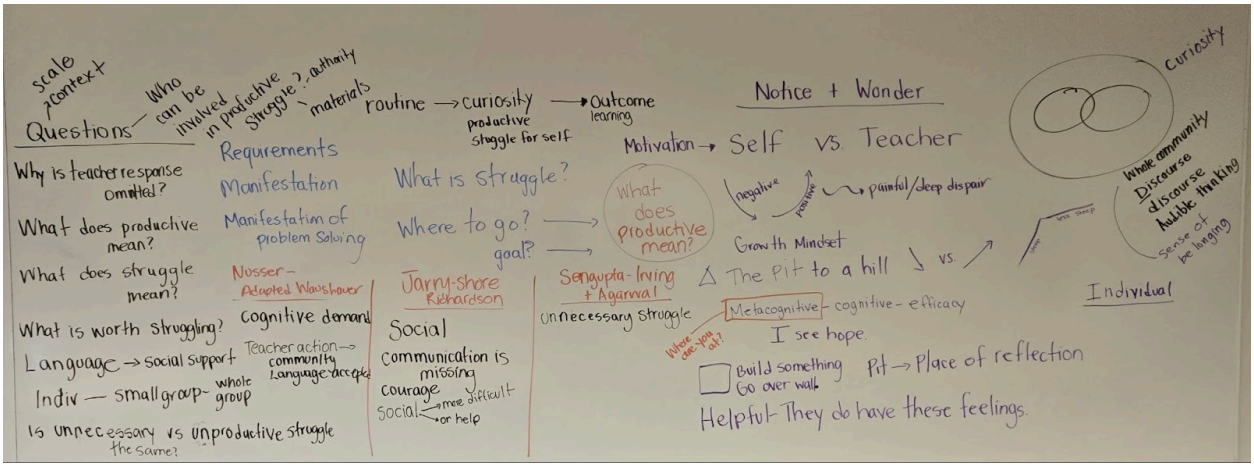

Figure 1: Session One Conversations

As shown in Figure 1, participants raised many of the same questions that the working group explored in our prior sessions at PME-NA 46. We concluded the session by asking participants

to ponder, “Why do the words we use to describe or quantify mathematical struggle matter for students, teachers, and teacher educators?”

Session Two

For this session, participants considered the challenges of *teacher productive struggle* (Baker et al., 2024). Our goal for this session were for participants to consider multiple perspectives. For example, what does it mean to help or intervene as a teacher when intending to support struggling students? From the perspective of mathematics teacher educators or math leaders, how can teachers be supported in embracing the vulnerability necessary to center mathematical sense-making in students’ thinking?

We began by having participants engage in a high-cognitive demand math task. Then, participants formed groups of four where they re-examined the task, each group member approaching the task from one of four perspectives:

4. Anticipating student approaches
5. Brainstorming teacher moves to use when implementing the task
6. What teacher struggles could occur while facilitating this task?
7. How do we support pre-service teachers in facilitating this task and supporting productive struggle more broadly?

Each group shared their responses to the four prompts which we recorded on the board (Figure 2). We then tied our group discussion to Baker and colleagues’ (2024) work on the relationship between student and teacher productive struggle. We found that our identified “teacher struggles” aligned with and extended the experiences identified by Baker and colleagues (2024). As with the previous day, participants posed several questions and wonderings which were documented and explored in the following session.

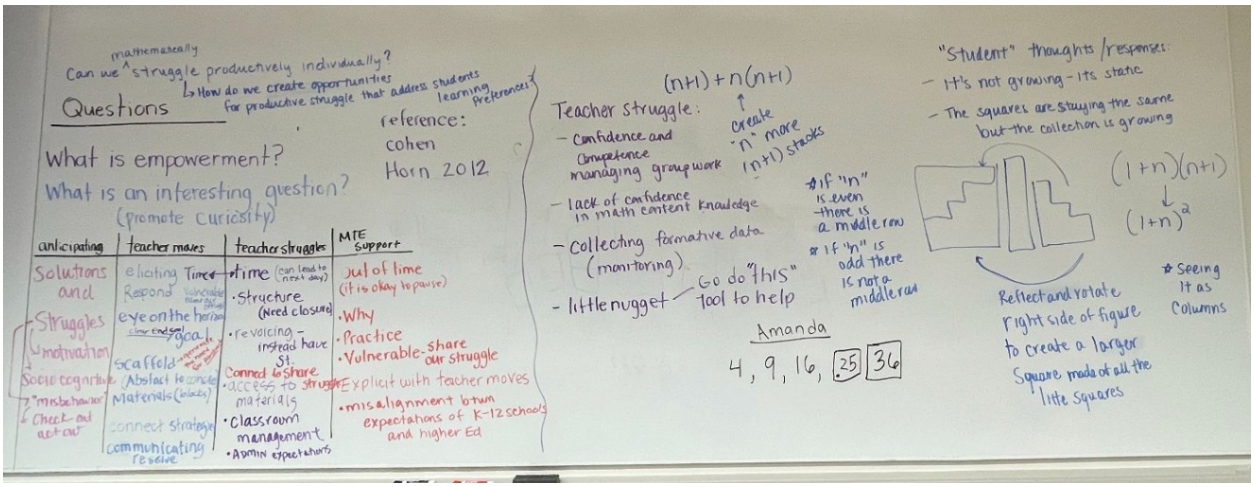

Figure 2: Session Two Conversations

Session Three

In this session, we opened the session with a discussion of, “What does “empowerment” mean to you?” in mathematics. Our goal was to link established research on productive struggle (Hiebert & Grouws, 2007; Jarry-Shore & Richardson, 2024; Warshauer, 2015) with literature on rehumanizing mathematics, to demonstrate how establishing a safe environment for routine

engagement in productive struggle serves to development of a sense of belonging in mathematics (A Pathway to Equitable Math Instruction, 2021; Kalinec-Craig & Rios, 2024). Participants readily identified mathematical identity components. We built upon this discussion to segway into telling a story about students who had their own language and expressions to describe production struggle and frustration.

Between PME-NA 46 and 47, working group members discussed the symbiotic nature of learners' sense of belonging in mathematics and experiences of productive struggle. We brought session participants into this conversation by inviting them to connect the pieces shown in Figure 3 with the theoretical frameworks of productive struggle discussed in Session One.

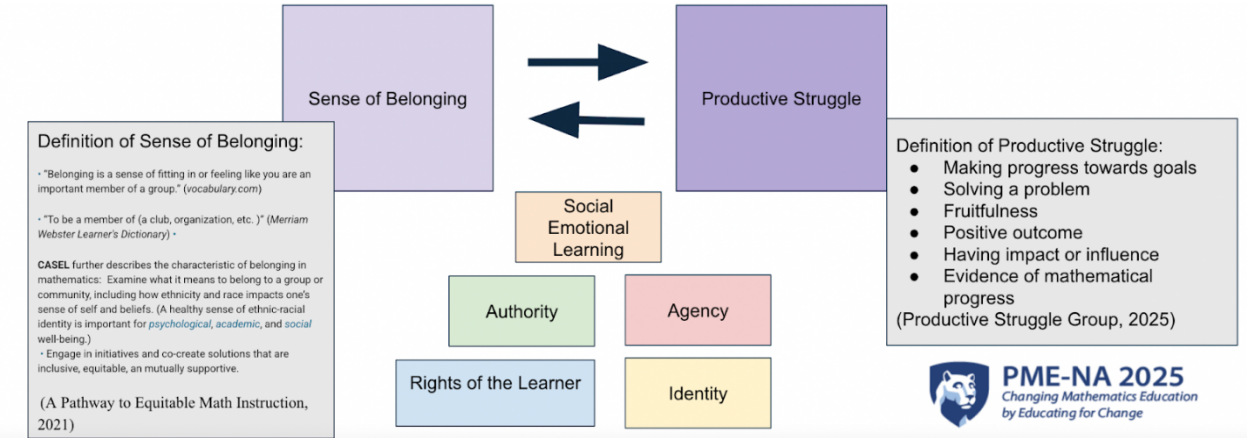

Figure 3: Slide Prompting Participants to Examine the Relationship of Sense of Belonging and Productive Struggle

Participants began working independently, connecting the concepts of agency, authority, identity, social emotional learning with the rights of the learner, sense of belonging and productive struggle, crafting their theoretical models. Some participants added on to the existing frameworks, while others connected the concepts shown in Figure 3 in new ways. Figure 4 shows two of the models that participants created and shared with the group.

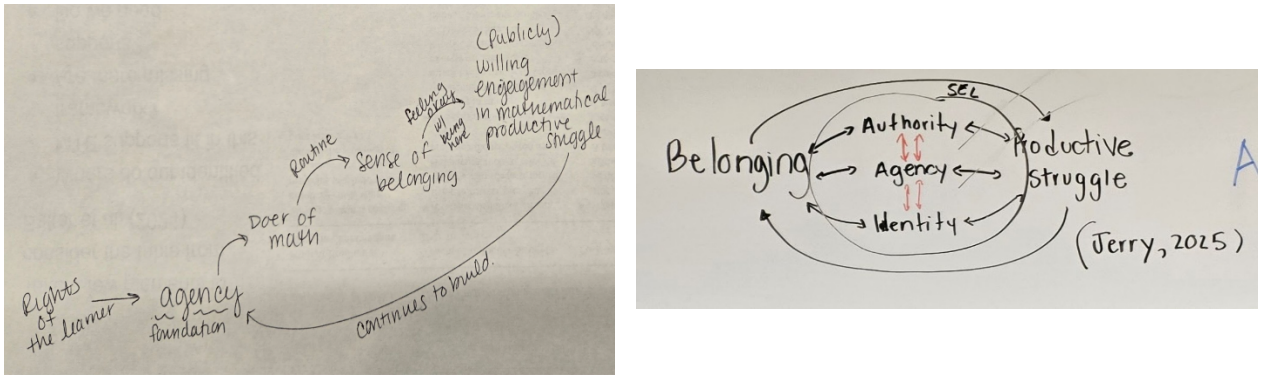

Figure 4: Theoretical Models of the Relationship Between Sense of Belonging and Productive Struggle

Our discussions of the proposed models and frameworks helped to solidify our understandings of the concepts and refine our ideas. We aim to explore these models further in the next iteration of the working group at PME-NA 47.

After the Conference

The productive struggle working group continues to meet online monthly. These meetings are a space for novice and experienced mathematics educators and teacher educators to collaborate. During these meetings we pose wonderings, develop lines of inquiry, share literature on productive struggle, and provide feedback on each other's research and drafts for publication.

Currently, members of the working group are editing a special issue of *Investigations in Mathematics Learning*. This special issue seeks to promote and formalize the ideas explored by the working group. Contributing authors were invited to refine existing definitions and conceptions of productive struggle, examine the social dimension of mathematics learning and its impact on students' experiences of productive struggle, refine methodological practices of studying students' experiences of productive struggle in context, and to explore the roles of individual and collective productive struggle in developing students' authority, agency, and sense of belonging in mathematics.

Next Steps

Continuing to build on our prior efforts, our proposed working group sessions for PME-NA 2026 will: (1) exploring evidence of mathematical struggle and mathematical progress; (2) connecting that evidence to culture, language, and sense of belonging; and (3) identifying instructional tools and technology that support the cultivation of productive struggle.

Additionally, outside of the conference, working group members are in the beginning stages of a research project where they are gathering empirical evidence to support the theoretical framings proposed by the group. We aim to have IRB approved data to explore with participants at PME-NA 48.

MATHEMATICS EDUCATION FOR CITIZENSHIP: BRIDGING THEORY AND PRACTICE

Amy Brass
University of New Mexico
abrass@unm.edu

Shophika Vaithyanathasarma
Boston College
vaithyan@bc.edu

This working group met at PME-NA 47 for the first time to build a community around mathematics for citizenship. This year, we gather again to continue examining mathematics for democratic citizenship related to interpreting public claims, engaging with social issues and injustices, and supporting equity and social responsibility. We aim to deepen our understanding of mathematics for citizenship in ways that connect theory to classroom practice as we explore the unique roles of mathematics teacher educators and mathematics education researchers in this endeavor. The working group is participant-driven and aspires to be a place for building community with participants interested in relationships across mathematics, mathematics education, citizenship, and democracy.

Keywords: Social Justice; Instructional Vision; Equity, Inclusion, and Diversity; Curriculum

Given the current political climate in the world, the role of democratic citizens is a topic of increasing interest. This interest has extended to the field of mathematics education through work examining the role of mathematics in citizenship development (e.g., Brass, 2024; Geiger et al., 2023; Skovsmose et al., 2023) and calls from mathematics education organizations emphasizing the importance of mathematics in citizen development (e.g., Association of Mathematics Teacher Educators [AMTE], 2017, 2022; National Council of Teachers of Mathematics [NCTM], 2018, 2020). Yet, despite this increased interest, work connecting classroom practice of mathematics and citizenship integration is scarce. In the second year of this PME-NA working group, we continue to focus on mathematics for citizenship, which we view as the connection between mathematics education and democratic citizenship. We invite participants to explore these connections through mathematical thinking skills and mathematical content integrations that support students' development as citizens and interrogate social issues and injustices. Our goal for this working group is to consider theory in ways that bridge to classroom practice by deepening our knowledge of mathematics for citizenship. As we do this, we will focus on strategies that foster equity and social responsibility to prepare engaged and informed citizens in our diverse society (e.g., Gutstein, 2016; Jablonka, 2020; Weiland, 2019).

Taking a critical perspective, our working group will also explore the formatting power of mathematics in society (Skovsmose, 1994, 2021) and how it contributes to citizens' understanding of the world around them. We draw on Geiger et al. (2023), who emphasize that understanding the role that mathematics plays in formatting is "fundamental for informed and responsible citizenship so that citizens are empowered to engage with the mathematics underpinning societal issues" (p. 926). As our working group explores the formatting power of mathematics, we will examine the ways that mathematics can format social issues through the ways that mathematics is used to depict these issues and the ways that mathematics influences actions to address these issues (Skovsmose, 2021).

This working group seeks to answer these questions through our explorations:

- How is mathematics connected to citizen development?

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

- What connections between mathematics and democratic citizenship can be fostered and enacted in classroom practice? How can this be done?
- What influence does the formatting power of mathematics (Skovsmose, 1994) have on the ways in which citizens engage with the world around them?
- How can mathematics teacher educators and mathematics education researchers foster citizen development and work to defend democracy? What unique aspects of these roles aid or hinder this work?
- What does the absence of mathematics for citizenship from classrooms mean for our field? What impact does this have on society?

2026 Working Group Sessions

Session 1

We will begin by building shared understanding for new and returning participants. We will start with a short framing presentation by an invited scholar, Dr. Vince Geiger, introducing mathematics for citizenship and mathematics for democracy. This short presentation will include key ideas, such as the use of quantitative reasoning for interpreting public claims and using mathematics for engaging with social issues and injustices. Following the presentation, working group members will engage in a whole-group discussion to surface participants' questions, ideas, and connections. Building on this discussion, we will collaboratively articulate a working statement about the role and purpose of mathematics education for citizenship and democracy and begin mapping key dimensions of mathematics for citizenship related to mathematics education (e.g., Standards for Mathematics Practice [NGA Center & CCSSO, 2010], mathematics content standards).

Session 2

A short presentation introducing the formatting power of mathematics as a lens for examining how mathematics shapes what becomes visible, actionable, and considered true in society will be used to begin this Day 2. This will be followed by a whole-group discussion to unpack ideas related to the formatting power of mathematics and how these ideas connect to mathematics education. We will revise our purpose statement and map from Session 1, as needed, considering the formatting lens of mathematics. The remainder of Session 2 will be a working session. Participants will form groups based on shared interests (e.g., quantitative reasoning and public claims, curriculum/task design, teacher education, crises and the formatting power of mathematics, equity and social responsibility, empirical research designs). Groups will share ideas using a jigsaw format, so that participants leave with a range of approaches and examples beyond their initial group's case. This will lay the foundation for Day 3.

Session 3

The session will begin with a short presentation that highlights examples of scholarship and classroom-oriented work on mathematics for citizenship and democracy, with particular attention to tasks and instructional approaches that support students in interpreting and interrogating social issues and injustices. During this session, groups will work to brainstorm and outline next-step products such as a draft study design, a classroom task sequence, a teacher-education module, or a plan for cross-institutional collaboration. These discussions will support ongoing community-building and contribute to future research and teaching collaborations among working group participants. To encourage progress on these collaborations, we will also solidify plans for meeting after the 2026 PME-NA conference during this session.

WORKING GROUP REPORT

MATHEMATICS EDUCATION FOR CITIZENSHIP: BRIDGING THEORY AND PRACTICE

Shophika Vaithyanathasarma
Boston College
vaithyan@bc.edu

Amy Brass
University of New Mexico
abrass@unm.edu

This report shares the details of our first working group meeting at PMENA-47. The aim of the first meeting of this working group was to build a community around mathematics for citizenship. The group made progress towards developing a working definition for citizenship and clarifying the role of citizenship for mathematics. Members of this group continue to meet regularly as we continue to solidify our shared understanding of mathematics for citizenship and generate research ideas based on our shared interests. In the report, we summarize the progress made at the PME-NA conference in 2025, provide updates about our shared work after the conference, and share our future plans for the working group.

Keywords: Social Justice; Instructional Vision; Equity, Inclusion, and Diversity; Curriculum

History of Working Group

Building on scholarship that frames statistical literacy as an intersection of statistical and critical literacies (Gal & Geiger, 2022; Weiland, 2019), and that highlights quantitative civic literacy as essential for evaluating mathematical claims in political and social contexts (Raygoza, 2019; Steen, 1999), this group was formed to explore how these ideas can be meaningfully translated into teaching and teacher education. The group's discussions also centered on mathematics as a practice that supports critical thinking, democratic deliberation, and the justification, critique, and negotiation of ideas (Brass, 2024; Geiger et al., 2023; Jablonka, 2020; Maas, 2019; Skovsmose et al., 2023). At the same time, members were motivated by equity and justice concerns, particularly the need to help students recognize how mathematical domains and policies can reproduce or challenge social inequalities while developing agency to question and act on injustice (Gutstein, 2016). In response to increasing calls from organizations such as AMTE (2017, 2022) and NCTM (2018, 2020) to integrate civic dimensions into mathematics instruction and the persistent gap between conceptual scholarship and classroom practice, the working group was established to begin bridging theory and practice and to lay the foundation for future empirical research.

Work at PME-NA 47

This working group formed around a shared interest in understanding and strengthening the relationship between mathematics education and citizenship. Here, we detail the activities and discussions that took place within our working group during the 2025 PME-NA Conference.

Day 1: Learning Working Group Members' Interests

Day 1 focused on sharing responses to guiding questions to better understand working group members' interests, priorities, and experiences. This helped establish a collaborative foundation and highlighted how working group members approached "citizenship" from multiple perspectives, including classroom practice, research design, and community engagement. These were the guiding questions to which working group members responded:

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

- What is the fundamental purpose of mathematics education in a democracy? What structures exist or are needed to operationalize this commitment?
- How do you define citizenship in your own work context or daily life? What dimensions feel more relevant to your practice?
- When and how do you see mathematics intersecting with citizenship in your work or daily life? How does citizenship show up in what students bring to the mathematics classroom?
- Think of a moment when mathematics influenced a civic or social issue that mattered to you. What mathematical concepts were involved, and what impact did they have?
- What mathematical ideas feel naturally or more readily connected to citizenship concepts and why do you think these connections emerge?

Figure 1, Figure 2, and Figure 3 capture our working group members' individual responses to these questions. Working group members engaged in collective discussion about these responses as we sought to understand and clarify different perspectives related to mathematics and citizenship within our group. Through our collective discussion, members of the working group explored the concept of citizenship, emphasized the aspects that we see as essential to citizenship, and clarified the relationship between mathematics and citizenship.

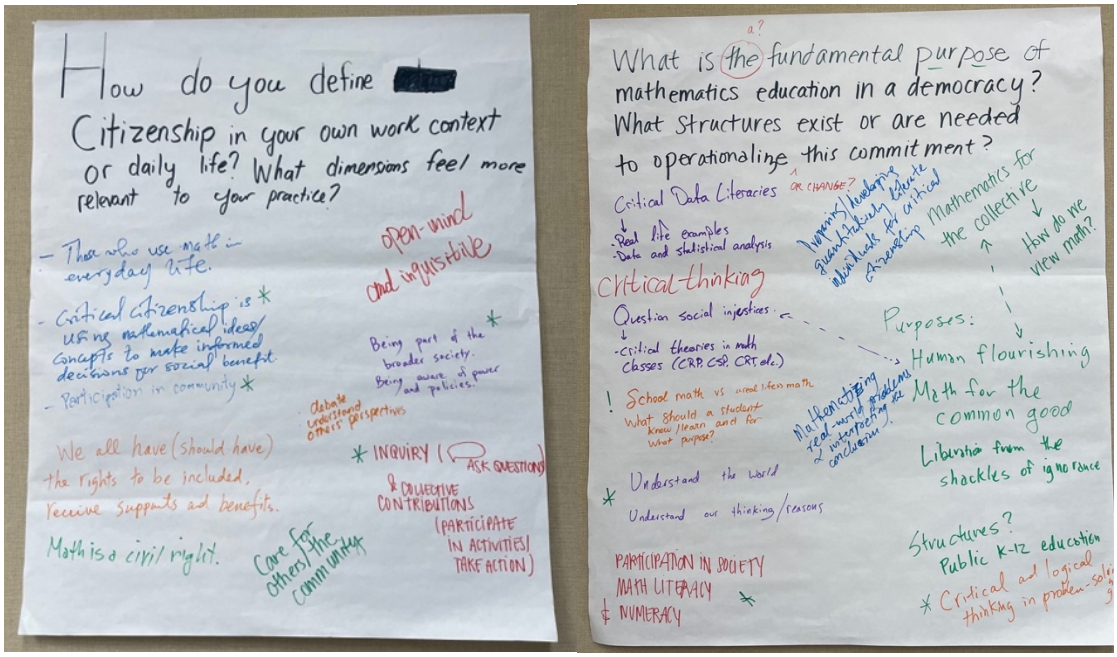

Figure 1: Responses Generated by Working Group Members, Part 1

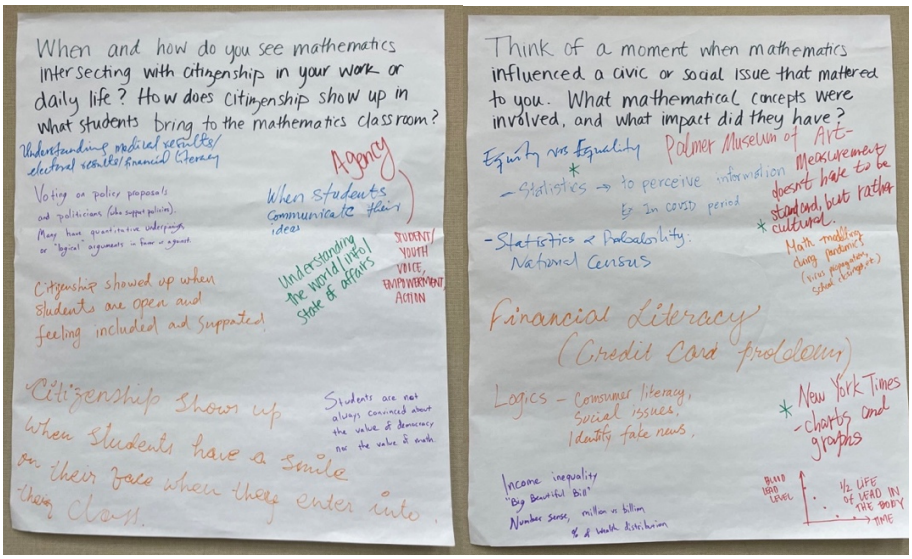

Figure 2: Responses Generated by Working Group Members, Part 2

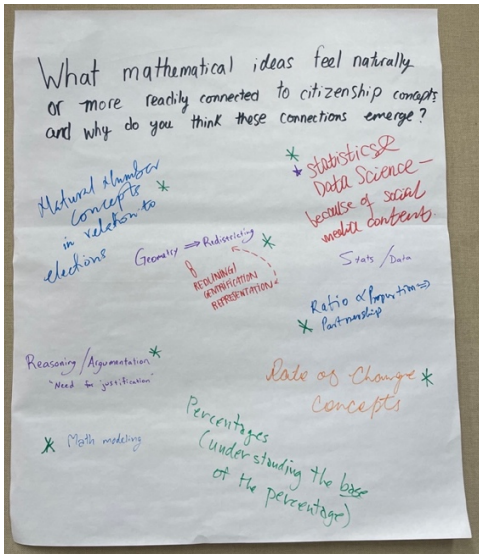

Figure 3: Responses Generated by Working Group Members, Part 3

Day 2: Defining Citizenship and Clarifying the Role of Mathematics

On Day 2, working group members worked to build a common language for mathematics for citizenship, explored how mathematics for citizenship connects to civic participation and belonging, and considered how mathematics can function as a tool for reasoning about public issues. We began our discussions using the shared experience of the *Counted Out* (Abeles, 2024) screening from the previous day of the conference. Working group members discussed the screening and its connection to mathematics for citizenship, using it as a springboard to examine equity, participation, and the role of quantitative information in public life.

Working definition of citizenship. To ground our discussion, we began by talking through widely used lenses for thinking about citizenship. Westheimer and Kahne's (2004) framework helped us distinguish among personally responsible, participatory, and justice-oriented

conceptions of the "good" citizen. Building from that conversation, we also talked through Banks's (2017) complementary emphasis on who is recognized as a citizen and what rights these citizens have, highlighting how some groups experience failed citizenship when they are structurally excluded. We used these frameworks as starting points to collectively co-construct our own working definition of citizenship. Through iterative, whole-group discussion and revision, working group members negotiated shared language and priorities, as you can see in Figure 4.

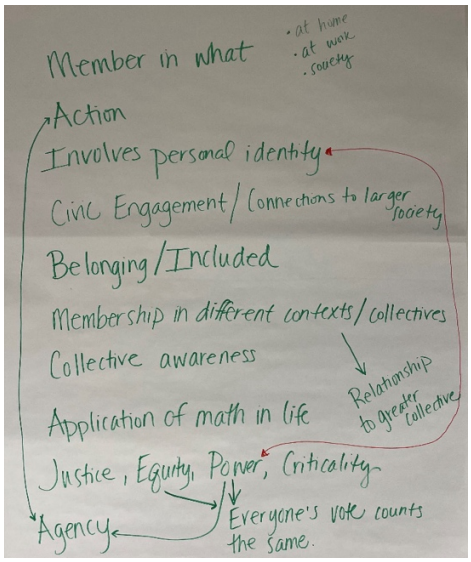

Figure 4: Working Definition of Citizenship

The group explored citizenship as participation in community, the right to be included and supported, and the responsibilities and care that sustain communities. Working group members also emphasized that citizenship involves awareness of power, politics, and decision-making processes and that being a citizen can mean engaging actively, supporting others, debating, and contributing to communal life in "civilized" and constructive ways. An important nuance emerged: citizenship is not only an external designation but also part of personal identity and how one is perceived and accepted by others. This raised key questions about who "decides" citizenship and how belonging and equal rights are negotiated in spaces like schools and communities.

Mathematical domains in relationship with citizenship. A brief presentation was given to discuss the common mathematical domains that are in conversation with citizenship. Quantitative literacy was among the mathematical domains that we discussed, as several members of the working group conduct research focused in this area. We also talked about the use of data, statistical literacy, and mathematical modeling as platforms for emphasizing the relationship between mathematics and citizenship. There were also working group members who conduct research focused in these areas. The working group members also discussed mathematics for citizenship through reasoning, where quantitative reasoning, mathematical thinking, and critical thinking serve as tools for interpreting information, making judgments, and participating in civic life. These discussions led to broader questions: what are the foundations and purposes of schooling, and why do we teach mathematics?

Small-group research conversations. Working group members met in small groups to share research interests and possible directions. This provided a setting for working group members to share their thoughts, current research projects related to mathematics for citizenship, and ideas for future work. After meeting in small groups, we reconvened as a larger group and shared the ideas that were generated. Topics for potential collaborative work included using mathematics as a decision-making tool for public issues (e.g., vaccines and herd immunity), designing horizontal and vertical studies relating mathematics and citizenship across grade levels, linking statistics to social justice contexts, and exploring interdisciplinary approaches that combine mathematics and social science methods with preservice teachers. One of the themes that emerged during these discussions was linked to measurement and impact. Working group members questioned how the effectiveness of mathematics for citizenship can be evaluated, especially since citizenship development is not confined to classrooms. This prompted early thinking about possible study designs that look across years and contexts (e.g., examining representations of citizenship across multiple courses or tracking students' opportunities to use mathematics for civic reasoning over time).

Day 3: Future Directions and Collective Outputs

Due to travel schedules, Day 3 was conducted with a smaller group. Working group members proposed several future directions: (1) developing grade-spanning activities and materials related to civic issues, (2) continuing to refine and make explicit a shared definition of mathematics for citizenship, (3) articulating the role and purpose of mathematics for citizenship with the longer-term goal of a position statement, (4) mapping mathematics for citizenship to established mathematics practices and principles to clarify alignment and support uptake by educators and researchers. Reflections on these future directions continued between conferences and formed the foundation of our working group plans for the 2026 PME-NA conference.

Progress Between Conferences

After the conference, the working group held three meetings focused on community-building and sustainability. These meetings centered on hopes and expectations for the future and reinforced a shared desire to keep the group intellectually active by continuing to share papers and exchange ideas. These post-conference discussions functioned as a platform for clarifying goals, identifying what members need from the community, and maintaining momentum before the submission of the next working group proposal. These discussions also led to several questions the working group would like to address in the future.

Questions to Address in the Future

The questions build on our work from the 2025 conference and provide direction for our future working group sessions:

- What are specific ways in which mathematics is connected to citizen development?
- How can the connections between mathematics and democratic citizenship be enacted in classroom practice?
- How does the formatting power of mathematics (Skovsmose, 1994) influence the ways we engage with mathematics for citizenship?
- What unique roles do mathematics teacher educators and mathematics education researchers have in citizen development and in defending democracy?
- If mathematics is essential for developing citizens, but is absent from classroom practice, what does that mean for our field? What does that mean for our society?

WORKING GROUP ON UNIVERSAL DESIGN FOR LEARNING IN SECONDARY AND POSTSECONDARY MATHEMATICS

Laura Kyser Callis
Curry College
laura.callis@curry.edu

Jennifer Ceven McNally
Curry College
jmcnally@curry.edu

Mathematics classrooms at the secondary and postsecondary levels are increasingly diverse, challenging assumptions that learning environments are "one size fits all." This Working Group examines Universal Design for Learning (UDL) as an empirically based framework for intentionally designing mathematics instruction across secondary and postsecondary contexts that anticipates learner variability. Although widely used in K–12 and disability-focused contexts, UDL has received limited attention in PME-NA research. Participants will collaboratively interrogate research-based instructional practices through a UDL lens, examining affordances, access friction, and participation—particularly for students traditionally marginalized in mathematics education. The Working Group emphasizes interactive, case-based inquiry and aims for sustained collaboration beyond the conference.

Keywords: Instructional Activities and Practices, Students with Disabilities, Undergraduate Education

Mathematics educators recognize the complexity inherent in teaching and learning environments. Intersecting social, environmental, and instructional factors shape what and how students come to learn new mathematical ideas. As postsecondary mathematics classrooms become increasingly diverse in students' cognitive profiles, identities, and prior experiences, educators are recognizing that learning environments are not "one size fits all." Rather, instructors must be attuned to students' varied needs and intentionally design instructional environments that identify and mitigate barriers to learning.

Theoretical Background

Universal Design for Learning (UDL) is an empirically based design and learning framework that foregrounds learner variability and supports intentional instructional design (CAST, 2024). Rather than responding to students' needs through retrofitted accommodations, UDL emphasizes anticipating variability from the outset. Although UDL has been taken up in K–12 and disability-focused scholarship, it has received limited explicit attention in PME-NA proceedings and secondary and postsecondary mathematics education research. This new Working Group seeks to address that gap by situating research-based instructional practices in secondary and undergraduate mathematics within a broader UDL framework. We aim for this Working Group to offer regular communication and collaboration beyond the conference and to convene at future PME-NA conferences as well.

When framed as an emancipatory approach to ensuring equitable access to instruction, UDL offers a lens through which instructional practices can be interrogated for the benefit of students traditionally excluded from the research literature. In this Working Group, participants will collaboratively examine questions such as: What are the affordances of particular instructional practices, and for whom? Where does access friction arise that limits engagement, sensemaking, or participation? How might instructional design be reimagined to better support students at the margins of mathematics classrooms?

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Structure of the Sessions

Sessions are designed to be highly interactive and inclusive of participants' contributions, case studies, and inquiries. Activities will be planned as means for eliciting input from participants, recognizing that interactions that follow can be anticipated but not fully planned. Flexibility to pursue participants' favored inquiries is key to a successful Working Group.

The goals of the Working Group will remain constant. They are to:

1. Examine how secondary and postsecondary mathematics educators conceptualize and enact instructional design in response to increasingly diverse learners.
2. Use UDL as a theoretical and analytic lens to interrogate research-based instructional practices in undergraduate mathematics.
3. Center the perspectives and experiences of "students in the margins" to better understand how instructional environments enable or constrain access to mathematical learning.
4. Identify tensions, affordances, and limitations of UDL when applied to secondary and postsecondary mathematics contexts.
5. Develop a shared research agenda that supports ongoing collaboration beyond the conference, including joint manuscripts, symposia, and grant proposals.

On Day 1, the focus will be on getting to know the instructional and research contexts of the participants. Additionally, developing a shared understanding of the Universal Design for Learning framework and the principles of active design are critical. Tabletop activities where participants sort sample instructional practices and discuss how they relate to the Universal Design for Learning framework will support participants to get to know each other and dive deep into the UDL considerations. A case study that draws from the organizers' ongoing research on postsecondary mathematics instruction will launch small group discussions that map instructional practices to UDL principles, identifying affordances, access friction, and opportunities for redesign.

Day 2 will zoom out from specific examples and case studies of UDL-aligned instruction to focus on theoretical dialogue. Small group discussions will connect UDL to existing PME-NA research traditions, including work on instructional systems, participation, equity, and learning environments. There will be a focus on amplifying the voices of students in the margins to interrogate instructional environments, and identifying how this approach intersects with other research traditions.

The work on Day 3 will set the stage for ongoing collaboration between PME-NA conferences. Participants will be invited to propose or join on to shared research opportunities that can extend collaboration beyond the formal meetings of the Working Group. The session will conclude after collectively deciding the medium and frequency for ongoing collaboration, and providing online access to the products and working documents for the Working Group.

Ultimately, this Working Group aims to amplify the voices of students in the margins so that their particular needs are not overlooked in the design of mathematics learning environments. Anticipated outcomes include a shared language for discussing instructional design for learner variability, an articulated set of research questions and theoretical tensions related to UDL in postsecondary mathematics, and concrete plans for continued collaboration. Continuing, expanding, and propagating research that centers the experiences of students traditionally excluded from mathematics education research is an aspirational and optimistic outcome for participants in this group.

The Embodied Mathematical Imagination and Cognition (EMIC) Research Colloquium offers hands-on activities; demonstrations; and spaces for exploration and discussion of the embodied nature of mathematics education. For PME-NA 48, the EMIC group proposes a session that will allow the broad community of researchers engaged in this work to take stock of where the field stands and plan directions for the future. The session will be organized around a series of provocations, which will be shared on the first day the colloquium convenes, and whose purpose will be to challenge the assembled researchers to grapple with theoretical, methodological, and pedagogical/curricular challenges to the embodied cognition paradigm. The provocations will frame the demonstrations and explorations that will take place on day two and then be revisited on day three, as the group plans future collaborative research projects.

Keywords: Cognition, Learning Theory, Technology, Informal Education

Theoretical Background

A fundamental aspect of mathematical reasoning is that people impart symbolic notational systems and computational procedures with *meaning*. For example, early on, children regard NUMBER as more than just a visual string of numerals. To be meaningful, numbers evoke: spatial location along a line, magnitude, place value, cultural associations, and so on. At their core, theories of embodied mathematical cognition seek to offer accounts of how these meanings form from our sensorimotor interactions in the world and how we can design objects and experiences to cultivate these formations, foster inclusive and effective educational experiences, and reliably test hypotheses and assess educational outcomes of all students (e.g., Abrahamson et al., 2020; Alibali & Nathan, 2012; Arzarello et al., 2009; de Freitas & Sinclair, 2014; Edwards et al., 2014; McKinney de Royston et al., 2020; Radford, 2009; Walkington et al., 2021, 2024).

A Brief History and Motivation of the EMIC Working Group

The EMIC working group started at PME-NA 2015. We have convened annually at PME-NA ever since, organizing events that investigate the embodied nature of mathematics through physical and digital games, arts and crafts, individual and collaborative dance and movement, language, perception, immersive experiences, and more. EMIC members continue to explore new technologies and research methods that acknowledge and leverage the inherently embodied nature of mathematical cognition. Recent work goes beyond scholarly publications to offer novel technologies scaled for classroom use, special education, and multilingual learners; teacher learning for instructional uses of gestures; and webinars for teachers and parents.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Embodied Learning at a Crossroads: Provocation, Reflection, and Reimagination

With more than a decade of history, the EMIC community now encompasses a broad and expanding network of researchers working within diverse theoretical framings under the 4E cognitive umbrella (Extended, Enacted, Embodied, and Embedded). Over the years, EMIC has become a collaborative space where mathematics education researchers have shared design-based work that has broken new ground theoretically, methodologically, and pedagogically. For example, last year's gathering featured interactive demonstrations illustrating how emerging technologies (e.g., robotics; haptic interaction; author, date), analog tools (SunRules; author, date), children's toys (Speks Toys, Play-Doh; author, date), and ancient, enactive practice (yoga; aiuthor, date) can create contexts where embodied mathematical learning can emerge. Our vision for this year's gathering is twofold. First, we aim to once again feature interactive demonstrations from both long-standing and new members of the EMIC community. Second, we seek to engage collective visioning: taking stock of where we are as a field and imagining a future in which embodied design-based work will continue to thrive.

To frame this collective visioning, we will organize this year's sessions around a series of *provocations* that will be presented during the first day of the working group. We use *provocation* in the sense of a spirited, yet collegial, challenge. Our aim is to stir the collective imagination of participants and identify the big-picture questions that our field needs to wrestle with in the years ahead. We will organize the three days of the colloquium as follows:

On Day 1, we will begin with introductions and an overview of embodied mathematical thinking, teaching, and design principles. Participants will then be invited to share Provocations—broad questions related to theoretical, pedagogical, or practical challenges we're wrestling with in our work. These include questions such as: *How do I respond to reviewers who are looking for evidence that's incompatible with my epistemological commitments? How might we build toward greater scientific consensus when embodiment scholars draw from diverse theoretical perspectives? How might access to new stores of multimodal data from federally funded initiatives shape and advance the kinds of questions and methods we will pursue over the next several years?*

On Day 2, members of the working group will engage participants in demos of activities that span K-16 content areas. The demos will be framed by introductory discussions that (a) call back to the provocations from Day 1 and that (b) foreground theories of enactive and embodied cognition to highlight the research underpinnings of their designs. Following the demos, the session will conclude with a group reflection that examines how various theories of embodied or enactive design were made evident through the implementations of the different activities.

On Day 3, we will reflect on Day 1 and Day 2 experiences in relation to the broader question of how embodied and enactivist approaches to education can enable novel forms of mathematical activity by grounding conceptual understandings of mathematical ideas in sensorimotor and materially agential interactions and experiences. We will follow by returning to previously raised provocations (and perhaps raise new ones), share emerging insights, and plan new collaborations to pursue them over the course of the year.

The Embodied Mathematical Imagination and Cognition (EMIC) Working Group was established in 2015 at the annual PME-NA conference. As an interdisciplinary group of researchers, teachers, students, and practitioners, EMIC has strived to advance our understanding of how our physical experiences and body-based resources impact the ways we learn mathematics. Over the past several years, EMIC's founding members have collaborated on initiatives to a) expand this area of research through grants, workshops, and publications, b) share these findings with teachers and practitioners, and c) grow the community through new members and opportunities for participation. This progress report highlights the progress and accomplishments of EMIC and its members through 2025 at PME-NA 47.

Keywords: Technology, Cognition, Informal Education, Learning Theory

A Brief History and Motivation of the EMIC Working Group

The first meeting of the EMIC working group took place in East Lansing, MI during PME-NA 2015. It has a somewhat longer origin, however, growing out of several earlier collaborative efforts to review the existing literature, document embodied behaviors, and design theoretically motivated interventions. One early event was the organization of the 2007 AERA symposium, "Mathematics Learning and Embodied Cognition." This and other gatherings led to a funded NSF "catalyst" grant to explore a Science of Learning Center, which was to involve scholars from multiple institutions and countries. Though unfunded, those SLC efforts shaped a subsequent 6-year NSF-REESE grant, "Tangibility for the Teaching, Learning, and Communicating of Mathematics," starting in 2008. Interest from the International PME community in this topic grew and led to special issues of *Educational Studies in Mathematics* (2009), *The Journal of the Learning Sciences* (2012), and an NCTM 2013 research pre-session keynote panel, "Embodied cognition: What it means to know and do mathematics," along with a series of academic presentations, book chapters, and journal articles, as well as several masters' theses and doctoral dissertations. By now, several research programs have formed to investigate the embodied nature of mathematics (e.g., Abrahamson 2014; Alibali & Nathan, 2012; Arzarello et al., 2009; de Freitas & Sinclair, 2014; Edwards et al., 2014; Lakoff & Núñez, 2000; Radford 2009), demonstrating a "critical mass" of projects, findings, senior and junior investigators, and conceptual frameworks to support an on-going community of like-minded scholars within the mathematics education research community.

It was within this historical context that approximately 22 members of PME-NA 2015 came together for three 90-min sessions of semi-structured activities. On Day 1, the organizers

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

engaged attendees in some of the body-based math activities used in their research on proportional reasoning and geometry. One activity (Figure 1b) engaged participants in a projection activity using Alberti's Window, which helped experience the role of body perspective on form and representation. We discussed how embodied theories are advancing our understanding of mathematical thinking, and how these ideas are shaping a new class of educational interventions. During Day 2, we used hands-on activities to expand our own understanding of topology. We then built on the emerging rapport among the group to hold a facilitated discussion of the potential intellectual benefits of forming a self-sustaining Working Group on embodied cognition, along with the necessary infrastructure it would need to maintain. Several concrete proposals led to the list of Future Steps on Day 3. However, before we tackled those matters, participants began the session doing math games and activities in small groups, including Spirograph, Set, Rush Hour, Tangrams, and Mastermind. We reflected on how some games and activities draw people into rich mathematical thinking and actions, and how we naturally engage in math through these activities. Day 3 culminated in an organized list of Future Steps. We have convened annually since.

Figure 1: A Small Selection of Embodied Activities Created by EMIC Organizers and Experienced by EMIC Participants. *Clockwise from top left*: (a) Experiencing Geometric Transformations; (b) Acting Out Geometry Conjectures; (c) Constructing Icosahedra First as Small, then at Human Scale; and (d) Enacting Topological Relations

Founding Members

The EMIC community has welcomed several new members since its inception in 2015 and the leaders of our working group at PME-NA have shifted each year to reflect the focus of each annual meeting. Below are the founding members of EMIC who have led the charge for many of this group's collaborations within and between PME-NA convenings.

- Candace Walkington, Southern Methodist University
- Caro Williams-Pierce, University at Albany, SUNY / University of Maryland
- David Landy, Indiana University / Netflix
- Dor Abrahamson, University of California, Berkeley
- Erin Ottmar, Worcester Polytechnic Institute
- Martha W. Alibali, University of Wisconsin-Madison
- Mitchell J. Nathan, University of Wisconsin-Madison
- Ricardo Nemirovsky, San Diego State University
- Rogers Hall, Vanderbilt University

Collective Efforts and Accomplishments

Beyond PME-NA, EMIC members have actively collaborated over the past several years to continue advancing this field of research, bridging the gap between research and classroom practice, and expanding the EMIC community. Below, we provide overviews of the progress and accomplishments shared by members of our group (see Table 1).

Table 1: Events Organized by the EMIC Community Since PME-NA 2015

Year	Event
2015	EMIC Working Group at PME-NA 37. Theme: Embodied Mathematical Imagination and Cognition. The launch of the working group and community at PME-NA.
2016	EMIC Working Group at PME-NA 38. Theme: Finding Common Interests for Creating an Online Community of Scholars.
2017	EMIC Working Group at PME-NA 39. Theme: Embodiment at the Crossroads of Mathematical Collaboration. Topics included the power of collaborative gestures.
2018	EMIC Working Group at PME-NA 40. Theme: Extending Theoretical Frameworks of Embodied Cognition to Assessing and Assisting Mathematics Learning.
2019	EMIC Working Group at PME-NA 41. Theme: Co-design of Novel Embodied Instructional Activities for Mathematics Education. Topics included the influences of eliciting movement in physical and video game-based learning activities.
2019	(May) NSF-funded EMIC I Workshop at the University of Wisconsin-Madison.
2020	(May). EMIC Virtual Panel #1. Hosted by embodiedmathematics.com.
2020	(October). EMIC Virtual Panel #2. Hosted by embodiedmathematics.com.
2021	(June; postponed from June 2020). EMIC Virtual Working Group at PME-NA 42. Theme: How Embodied Mathematics Can Bridge Cultural Divides. Topics included varieties of cultural and linguistic ways of expressing mathematical ideas.
2021	(October). NSF-funded EMIC II Workshop at Colorado State University, Fort Collins.
2021	(October). EMIC Research Colloquium at PME-NA 43. Theme: Promoting Inclusive Mathematics Education Research and Practices. Topics included exploring varieties of physical inclusivity in different virtual stations and immersive technology.

2022 Members of the EMIC community hosted visiting scholars, practitioners, and students to their home sites for activities to promote embodied mathematics teaching and learning; including: methodology training, new collaborations, workshops (e.g., dance + math).

2022 (November). EMIC Research Colloquium at PME-NA 44. Theme: Critical Dissonance and Resonant Harmony. Topics included traditional vs. embodied views of mathematics and embodied activities for more socially-just education.

2023 EMIC Research Colloquium at PME-NA 45. EMIC members Karl Schaffer and Mitchell Nathan held a 2-day dance + math workshop in Madison WI with students and faculty from dance, theater, math, and education.

2024 EMIC Working Group at PME-NA 46. Theme: *"Envisioning the Future of Mathematics Education in Uncertain Times"* Experience perspectives across multiple institutions of mathematical activity, teaching, learning, assessment, and design for current uses and challenges of VR/AR to foster inclusive and effective educational experiences.

2025 EMIC Working Group at PME-NA 47. Theme: *"Changing Mathematics Education by Educating for Change."* We further describe these activities below.

Recap of EMIC 2025: Changing Mathematics Education by Educating for Change

At PME-NA 47, the EMIC Research Colloquium built on the conference theme to consider the rapid changes within mathematics education through an embodiment lens. This year we focused on hands-on activities and group discussions around the central questions that frame this year's conference theme. This enhanced the conversations and led to new ideas, perspectives and collaborations. Activities addressed (1) *Inclusion and Epistemic Justice* to meet needs of neurodivergent and neurotypical children (2) *Mathematics as Transformative*. Strategic uses of physical materials and digital holograms in immersive environments using AR/VR technology. (3) *Respond to the Changes in a Dynamic World*. Advancements in sensor and display technologies, research methodologies, and learning theories provide an ability to closely track these rapid changes and guide these developments in furtherance of educational objectives.

On Day 1, after introductions of approximately 20 attendees, participants experienced how embodiment can be a frame for surfacing key dimensions of epistemological pluralism and opening new pathways for inclusive instruction; querying embodiment theory through work with marginalized learners and neurodivergent and neurotypical children. Activities included: *Balance Board Math* (Figure 2) to investigate ways periodic movement (common in "stimming") can support understanding of periodicity and transcendental functions (Tancredi & Abrahamson, 2024); *Play-Doh* to explore integral calculus; and magnets and loops to delve into notions of "*Stretchy Minds*" and how we think about agency and protecting the structures that shape identity within institutional hierarchies of authority.

Figure 2: Play-Doh to Explore Integral Calculus, Balance Board Mathematics, Multiplication by Sunlight with a SunRule

On Day 2, we built *SunRules* (Dimmel et al., 2021) using craft materials and geometry, and then went outside to use the SunRule as a way to explore multiplication and division (Figure 2). People were in small groups and explored trigonometry and geocentric geometry. We debriefed in a whole group discussion.

On Day 3, we engaged in *Math Yoga* and ways of connecting with our bodies in stable and less stable configurations to focus on basic properties of geometry and linear and nonlinear relationships. The last 30 mins of Day 3 were spent debriefing and community building, addressing these prompts:

1. Reflect on what we've learned, what ideas we've generated, lingering questions
2. Future math of embodiment in education
3. How to collaborate with educators and teachers to work together towards embodiment—hurdles to overcome to implement—research to practice and practice to research

Highlights: Funded Grant Proposals and Projects

1. NSF EMIC I. A successful proposal to host a three-day NSF Synthesis and Design workshop, May 20-22, 2019, hosted by University of Wisconsin-Madison. The theme was "The Future of Embodied Design for Mathematical Imagination and Cognition" with 8 members serving as organizers. There were 50 attendees, comprised of international researchers, educational practitioners, and graduate students. All attendees presented. Keynotes from Dr. Brian Bottge and Dr. Maxine McKinney de Royston. This resulted in a white paper (Nathan et al., 2021) and open access article (Abrahamson et al., 2020).
    a. Follow-up collaboration between a WG faculty member (Abrahamson) and workshop participant (Danny Luecke), a Secondary Math Education Developer/Instructor at Turtle Mountain Community College, North Dakota, to create pre-/in-service teacher courses, Ojibwe Math I, II, and III, as well as a course titled Math In Context.
2. NSF EMIC II. A successful proposal to host a second NSF three-day Workshop in 2020 (delayed to Sept. 25-26, 2021), hosted by Colorado State University. The theme was: "EMIC: Professional Development for Undergraduate Mathematics Instructors" with 7

member organizers. Keynotes from Dr. Nathalie Sinclair, Dr. Brooke Ernest, Dr. Francisco Ortega, & Dr. Molly Kelton.
3. Several grants awarded by IES CASL program to study embodied cognition, including: the role of action in pre-college proof performance in geometry (Funded 2016-2025 for Nathan & Walkington); the use of perceptual learning technology to study algebra learning (Ottmar & Landy, 2018), use of augmented and virtual reality (AR/VR) to foster collaborative embodiment in immersive learning environments (Walkington & Nathan, 2020); and developing embodied AI (NSF; Nathan & Swart).

Products and Dissemination

1. Exhibit presented by Abrahamson and Rosenbaum at an NSF-funded WG meeting (EMIC I, Madison, WI) has led to a research project (Palatnik, WG faculty), a journal paper (Benally, Kimiko, Palatnik, Abrahamson, in press), and a Spencer proposal (item).
2. A joint symposium on Embodied Cognition with six members at the 2018 APA Technology, Mind & Society Conference (Harrison et al., 2018)
3. Publication of Nathan (2021), a textbook on embodied cognition for education.
4. A mechatronic embodied design for blind and visually impaired geometry students, in collaboration with the PhET lab and the CHROME lab wins Best Paper both at two annual conferences (Lambert, Fiedler, et al., 2022; Lambert, Tancredi, et al., 2022).
5. Published Walkington et al., (2022) on the cognitive relevance of actions for math ed.
6. Best Design Paper at ICLS for *The Hidden Village*, an embodied video game for improving mathematical insight and geometry proof production (Nathan et al., 2022).
7. Springer publishers solicited a chapter on embodied design for its forthcoming handbook of digital educational resources (Abrahamson et al., in press).
8. iLRN 2025 *Best Doctoral Colloquium Paper "*A Comparison of Teachers and Students in Categorizing and Representing Geometric Conjectures using AR Simulations" (UW).
9. Nathan, M. J. (2026, April 15). "Embodied Learning." Invited presentation to the Science of Learning Podcast Series, Dr. R. Keith Sawyer.

Community Engagement/Broadening Participation

1. Expanding a group website using the Google Sites platform to connect scholars, support ongoing interactions throughout the year, and regularly adding additional resources/activities https://sites.google.com/site/emicpmena/home
2. Several members creating and teaching Embodied Cognition and Gesture seminars at their institutions.
3. Extending the embodied-design agenda into special education in dialogue with Universal Design for Learning (Abrahamson, Flood, Miele, & Siu, in press)
4. Some senior members joining junior members' grant proposals as Co-PIs and advisors.
5. Interest from Head of Education R&D (Dr. Ilona łowiecka-Tańska) of the largest STEM museum in Europe (the Copernicus Hall of Science in Warsaw, Poland) to incorporate exhibits that had been developed for/at an NSF-funded WG meeting (EMIC I, Madison, WI) by Abrahamson and Rosenbaum.
6. EMIC Virtual Workshop #1, May 19, 2020. Theme: "Instructional Gestures for Classrooms and On-Line Mathematics Learning." Designed for an audience of K-16 teachers, parents, and mathematics education researchers. Panelists: Dr. Mitchell J.

Nathan, Dr. Martha Alibali, & Dr. Rebecca Boncoddo. Discussant: Dr. Hortensia Soto. Moderator: Dr. Caro Williams-Pierce. Hosted by embodiedmathematics.com.

7. EMIC Virtual Workshop #1, October 12, 2020. Theme: "Reading Group: The Future of Embodied Design for Mathematics Teaching and Learning." Convener: Dr. Dor Abrahamson, with a panel of authors from the (Abrahamson et al., 2020) paper.
8. Steering Committee, "Shaping the Future of Mathematics Learning and Education: A Scoping Workshop," July 23–24, 2024 (virtual workshop). Organizer: Dr. Soo-Siang Lim, Program Director, Science of Learning and Augmented Intelligence Program, NSF

Conclusions and Looking Ahead

Embodied accounts of reasoning, learning, and instruction are valuable frameworks for understanding and cultivating mathematics learning and teaching, and for informing a new generation of designs for interactive technologies, curricula, and assessments. The true potential for these ideas and practices to lead to transformational mathematics education depends on a thriving, informed, interactive community of scholars and practitioners who engage with these approaches, evaluate their impacts, and improve theory and practice. Thus, we see predictably recurrent events such as the PME-NA working groups and research colloquia as a cornerstone for maintaining a highly educated and engaged core community. We will continue to offer outreach events and pursue external funding for specialized workshops when the resources are available. Future research colloquium topics that offer particular promise to the mathematics education community are: Broadening participation in mathematics and STEM through embodied design for learning, teaching, and assessment; the growing access to augmented and immersive technology, such as AR and VR, as a means to transform learners' collaborative interactions with mathematical objects and phenomena (Walkington et al., 2021); and the potential for multimodal learning analytics that use machine learning methods to integrate complex data streams that include channels of speech, gesture, eye gaze, facial expressions, mouse clicks, and so on, to support more sophisticated descriptions of learners' behaviors that can lead to real-time formative assessment and predictive models of educationally important student outcomes (Abrahamson et al., 2021; Closser et al., 2021).

Acknowledgments

We wish to acknowledge the scholars and educators who have been the backbone of these interactive working groups, workshops, and panels by providing the stimulating intellectual environment for these ideas to take root and blossom. We also wish to acknowledge the generous funding from NSF, US Department of Education-IES, and how home institutions.

(RE)TURNING TO RELATIONALITY IN MATHEMATICS EDUCATION

VOLVIENDO A LO RELACIONAL EN LA EDUCACIÓN MATEMÁTICA

Ezra Gouvea
Rethink Learning, Inc.
ezra.gouvea@rethinklearning.com

Sofía Abreu
University of Texas at San Antonio
sofia.abreu@utsa.edu

Justice-oriented research and practice are often rooted in relational theoretical frameworks. Yet many of these frameworks contain a critique of representationalism that is nontrivial to understand and internalize. This critique is even more difficult to understand in relation to dominant ontologies of Mathematics. Our working group will connect people who are interested to learn more about research in Mathematics Education involving ethico-onto-epistemological frameworks, the associated critique of representationalism, or interested in helping to develop day-to-day practices of attunement to relationality. Our working group aims to build a community to sustain further research by initiating discussion, creating new communication channels for remaining in touch, and organizing small study groups for participants to engage deeply with each other's scholarship.

Keywords: Feminisms, Post Qualitative Research, Affect, Material Agency

Disciplinary practices cyclically emerge from relationships, and relationships are iteratively shaped by actions and practices. Like other disciplinary behavior, the practices that perpetuate forms of emergent *harm* can also be considered "inherent" to Mathematics (Leyva, 2022; Philip et al., 2018; Prescod-Weinstein, 2020; Vakil, 2020). We are troubled by this.

Anzaldúa (2002) moves us to consider how: "Change requires great heat. We must turn the heat on our own selves, *the first site of working toward social justice and transformation*" (p. xxxviii, emphasis added). We wish to explore how relational theoretical frameworks—and a (re)turn to the relationality inherent to Mathematics—can facilitate our teacher-selves to become better at sensing the ways in which Mathematics can problematically participate in perpetuating ongoing harm. With our individual teaching practices in mind, we feel that a relational (re)turning to self can also initiate profound (re)configurings of ourselves as inseparable parts of a spiritual flow where everything is alive and "full of thought, desire, contemplation and will" (Watts, 2013, p. 23).

For ourselves and for others, we have noticed that relational theoretical frameworks can be very generative and restorative while also being very bewildering. We seek to question "the very nature of mathematics … and how we are affected by that practice" (Gutiérrez, 2017, p. 2), but it is nontrivial to reimagine Mathematics without the familiar and dominant "two-world ontology" (Barad, 2003; St. Pierre, 2021) of representations. Our working group will be a place where we and our participants develop innovative approaches towards reconciling these tensions.

The first goal of our working group will be to document the configurations of disciplinary attunement to relationships that we and our participants have noticed in ourselves. Constrained within each of our institutional and curricular realities, we wish to explore more restorative forms of Mathematics that are compatible with ethico-onto-epistemological theoretical frameworks.

The second goal for our working group is to bring together scholars who are excited to reciprocally shape each other's thinking about response-able pedagogies (Chen, 2023), methodological implications (Rosiek & Snyder, 2020), and daily practices of justice (Everett,

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

2020). Our intentions resonate with Renato Marcone's (2025) recent suggestion to create small study groups of scholars who become deeply familiarized and engaged with each other's work.

Unlike one of the narratives about coming to know someone other than yourself, the two of us have noticed that coming to know each other's work has *not* necessarily involved coming to learn how to "complete" each other's sentences. Instead, we have noticed (Abreu & Gouvea, 2026) that *not*-knowing each other's thoughts (experiences, or detailed backgrounds of familiar literature) has created a fertile grounding for learning to "move-*with* each other's sentences," and learning to "*move* each other's sentences." We hope to facilitate networks of similar working relationships—meaningfully moving and being moved by others.

Outcomes and Organization

Through this working group, we will set up a communally-organized communication channel, and curate a shared Zotero library for references and collaborative commenting on PDF files. If there is sufficient interest among participants, we will organize a proposal for a special issue in an established journal. And most generatively, we will facilitate the organization of small, research-sustaining, groups that read each other's work deeply to collaborate, move each other's ideas, and move-with each other's ideas for progressing this work.

Day 1. Using trans-disciplinary guidelines (Ahenakew, 2016), we intend to begin by sharing different examples in which the intrinsic relationality of Mathematics becomes more palpable. We wish to help re-sensitize ourselves to the relationships that we are *already* a part of. We will document the practices of attunement to disciplinary relationships that are surfaced by our discussion and carry forward into the following days and in our working group report.

Day 2. Each of the three days will include classroom episodes to analyze. We plan for the second day to focus on specific ways to *talk* about mathematics, *teach* mathematics, and *engage in research* that are compatible with relational frameworks and the associated critique of representationalism. We will also engage with the ethical implications that are inherent to defining what others are or know (Warren et al., 2020). We will discuss developing practices of continually re-turning to turn over new understanding (Hamilton & Neimanis, 2018; Murris & Bozalek, 2019). We will summarize our conversations and points of confusion for the working group report.

Day 3. In our final session, our focus will be on daily practices of justice that are appropriate and feasible when working in the reality of our current time and places. Our intention and hope is for the working groups' discussion of day to day practices of justice to meaningfully complement the work of Rochelle Gutiérrez (2017, 2019) describing the concept of Mathematx. One aspect of our work is to find appropriate, accessible, and non-culturally-appropriating ways of being mathematical and relational that honor the intention and spirit of the Indigenous aesthetics that have inspired her formulation of Mathematx. We will be searching for subtle-yet-impactful ways of respecting students' many complicated disciplinary relationships, while also gently moving and moving-with student Mathematical thinking with care and attunement. We will document the highlights of our discussion for our report.

This new working group aims to formalize a collaborative inquiry community of math teacher educators exploring how practical tools can support teachers' enactment of equity-oriented math instruction in preservice and in-service settings. Drawing on Culturally Responsive Math Teaching Frameworks, participants share and analyze practical tools they have created or are developing, identify considerations for tool development and use, and share research approaches they have used to study tool development, use, and impact.

Keywords: Culture and Asset-Based Pedagogies; Equity, Inclusion, and Diversity; Instructional Activities and Practices

Working Group Goals and Strategies to Reach the Goals

The goals of this new working group are to: (1) create a community of math teacher educators (MTEs) who are interested or engaged in designing tools that support pre-service and/or in-service teachers enacting equity-oriented math instruction; (2) share participant-created tools; (3) identify considerations for tool development and use; and (4) discuss research approaches to study tool development, use, and impact. The working group organizers have each engaged in grant-funded work that includes designing tools to support teachers' enactment of equity-oriented math instruction. A critical part of that work has included gathering with MTEs from across the country who are engaged in similar efforts to discuss design principles, implementation efforts, and knowledge generation around tools with an explicit equity focus. A recent half-day workshop involving 35 MTEs surfaced a shared interest in creating opportunities for continued collaboration, leading to the vision for this working group.

To meet the goals outlined above, this working group will provide structured opportunities for participants to analyze tools using Zavala & Aguirre's (2024) Culturally Responsive Math Teaching frameworks and any other equity frameworks shared by participants, share examples of considerations and dilemmas that arise as teachers use tools, and explore research approaches that have been used to study tool development, use and impact. To support sustained collaboration, participants will also discuss opportunities for a special issue focused on the design and implementation for tools that support equity-oriented math teaching.

Theoretical Perspectives

While math educators and researchers have called for equitable and inclusive education for decades (e.g. AMTE, 2017; NCTM, 1989, 2000), the field continues to document inequitable and dehumanizing experiences and outcomes for historically excluded students, especially for those of Black, Latinx, and Indigenous descent (e.g., Berry III et al., 2014; Gutiérrez, 2018; Martin, 2019; NCSM & TODOS Math for All, 2016). In response to the critical need for

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

teaching that centers and leverages the contributions of students from marginalized groups (e.g., racial, socio-economic, gender, and linguistic), this working group gathers together and provides examples of tools developed by MTEs to support teachers enacting equity-oriented instruction and problematizes tool use in teacher education programs and professional development settings.

This working group focuses on "practical tools" (Grossman, Smagorinsky, & Valencia, 1999) that support teachers in developing knowledge-*in* and knowledge-*of* practice (Cochran-Smith & Lytle, 1999). Practical tools are "classroom practices, strategies, and resources" that have "local and immediate utility" for teachers (Grossman, Smagorinsky, & Valencia, 1999, p. 14). Such tools may also include "social routines" that "foster productive conversations about teaching and learning, build a shared language of practice and support principled risk-taking" (Thompson, et al., 2015, p. 1), and can prompt teachers to learn about (new) instructional practices and while navigating tensions related to these practices in their own classrooms. This working group will explore how these practical tools make teachers' equity-oriented dilemmas visible and support teachers in making instructional decisions that advance more equitable and just math learning experiences and outcomes for students.

This working group uses Zavala & Aguirre's (2024) Culturally Responsive Math Teaching (CRMT) Framework as a starting point to describe equity-oriented instruction. The framework includes three strands of instructional practices: (1) centering students' knowledges and identities; (2) sustaining high rigor with high support, and (3) disrupting power structures and advancing equitable participation. The working group will initially use this framework to create a shared understanding of equity-oriented math instructional practices and use it to critically analyze the opportunities and limitations in the tools participants have developed.

Working Group Organization and Participant Engagement

Session 1: Sharing participants' tools. Session activities: 1) introductions and session overview (5 min); 2) participants discuss in groups organizer- and participant-created tools, including (a) the strand(s) of the CRMT framework the tools intend to have teachers enact, (b) how the tools help teachers enact these instructional practices, and (c) the knowledge and skills teachers need to use the tools (45 mins); 3) whole group reflection of the tools shared and group responses to the guiding questions (25 min); 4) summary and preview of Session 2 (15 min).

Session 2: Tool development and use. Session activities: 1) overview of sessions 1 and 2 (5 min); 2) participants discuss in groups organizer- and participant-provided cases of tool development and use, including (a) how the tools were developed (including equity-related frameworks that informed design), (b) a comparison of intended versus enacted tool use (given the goals for teachers' enactment of equity-oriented instruction), and (c) equity-oriented dilemmas that surfaced during tool (re)development and use (40 min); 3) whole-group reflection identifying common themes and questions from small-group discussion of guiding questions (30 min); 4) summary and preview of Session 3 (15 min).

Session 3: Studying tool development, use and impact. Session activities: 1) overview of sessions 1-3 (10 min); 2) participants share and discuss in groups their research methods to study the development, use and impact of their tools, including: (a) research methods and frameworks used for data collection and analysis, and (b) what was learned from their study of their tool development, use and impact (in particular related to equity-oriented math instruction) (30 mins); 3) whole group reflection of the research methods shared and group responses to the guiding questions (30 mins); and 4) identify next steps for this working group (e.g. journal special issue, future working group session, reconvene at 2027 PME-NA annual meeting) (20 mins).

The focus of this working group is establishing and carrying out research agendas on instructional activities and practices in PK-12 mathematics education that have attained critical gravity in the teaching field but do not yet have a significant research base establishing their efficacy. We use the metaphor of Black Holes of research (Matney et al., 2020) to capture the gravitational pull of these activities, the obscurity surrounding whether and how the activities are efficacious, and the related research that has accrued around these practices and suggests their value. This PME-NA will be our group's third official meeting. Current subgroups focus on the instructional phenomena of Number Talks, Which One Doesn't Belong? and adaptive teaching. We invite new members to learn from and contribute to our ever-evolving approaches with the option of connecting with existing subgroups or initiating new collaborations.

Keywords: Instructional Activities and Practices, Research Methods

This working group formed around the common interest in researching instructional activities and practices in PK-12 mathematics education that are widely used and have significant anecdotal support. While research related to aspects of these practices also suggests they are valuable, the practices themselves have not yet been systematically and thoroughly researched. The Black Hole metaphor (Matney et al., 2020) frames our conversations as we consider the need to shed light on how these activities and practices are enacted and how and to what extent they are efficacious.

In this third meeting of our working group, we seek to further define our research agendas, coordinate specific research plans, and integrate new members according to their own research interests. Our goals for this meeting are:

- Welcome new participants, introduce the metaphor of Black Holes of research, and share recent individual and collective work towards illumination.
- Discuss experiences in seeking funding and approaches towards common challenges.
- Within and across focused subgroups, refine definitions of relevant constructs, including efficacy, and continue to develop appropriate methods for capturing those constructs.
- Develop clear timelines for accomplishing research agendas, including applying for grant funding and identifying PK-12 contexts in which to conduct research.

Session Plans

On Day 1 of the working group, we will introduce ourselves and welcome new members. We will orient the group to the metaphor of Black Holes of research surrounding instructional practices and activities and share examples of in-progress work to illuminate specific Black Holes. Each previously formed research subgroup will provide updates on the work they have engaged in over the past year. New members will have the opportunity to meet each subgroup to determine whether they would like to join or begin a parallel effort. Day 2 will be focused time for subgroups to meet and make progress according to the current status of their research efforts. Time will be set aside at the end of the session to reconvene and connect as a whole group. On Day 3, subgroups will develop specific timelines for the next steps of their research agendas.

The remainder of the proposal describes the current subgroups, allowing interested participants to determine whether there is an existing project they would like to learn more about. New members are also welcome to initiate new collaborations around other Black Holes.

Descriptions of the Focused Subgroups

The Number Talks (Humphreys & Parker, 2015; Parrish, 2011) group is exploring the possibility of using Artificial Intelligence (AI) to assist educators in designing and implementing Number Talks for upper elementary students focused on the conceptual foundation of fraction understanding. The group is particularly interested in whether differences exist among AI, mathematics education researchers, and educators in predicting and interpreting the strategies students employ during Number Talks. Findings will then be leveraged to explore potential ways to support educators in constructing Number Talks more effectively. The group will use working group sessions to write a proposal for funding from the National Science Foundation.

The Which One Doesn't Belong (WODB) (Danielson, 2016) group is collecting examples of WODB activities found in curricula as well as those that are teacher-created. The group will be developing a coding scheme to characterize features of the WODB activities which are consistently present and which vary across grade level, content, and source. Plans are to identify the core features of WODB activities as designed and develop a proposal to examine variations within teachers' enactment. We will examine relationships between these variations and a number of student outcomes.

The Adaptive Teaching subgroup is interested in how teachers plan for and enact instructional routines. Drawing from the work of Allen and colleagues (2013), we are interested in examining how teachers' enactment of these routines may deviate from provided curriculum materials or written lesson plans, demonstrating how teachers use their professional judgment to meet the needs of their students in the midst of instruction. Using this definition as a foundation, we are working to conceptualize what efficacious enactment looks like in context of the current instructional routines. In this capacity, we will discuss research methods capable of capturing these constructs integrated with the Number Talks and WODB subgroups.

Description for conference program: Our working group strives to plan and carry out research on under-researched instructional activities and practices in PK-12 mathematics education (also known as practices surrounded by "Black Holes"). In this third meeting of our working group, we will share progress of research projects in development and continue to collaborate to move these projects forward. Current projects plan to investigate Numbers Talks, Which One Doesn't Belong? and Adaptive Teaching. New participants are welcome to connect with existing groups or initiate new collaborations around activities or practices of interest. Please see our website at blackholesofmathematics.wordpress.com/.

PME-NA 47 REPORT: UNDER-RESEARCHED INSTRUCTIONAL ACTIVITIES AND PRACTICES IN PK-12 MATHEMATICS EDUCATION: ILLUMINATING THE BLACK HOLES

In our working group's second meeting, we welcomed several new members and made significant progress towards defining specific research foci. First, we provided an overview of the Black Holes of research metaphor (Matney et al., 2020) and discussed examples. The metaphor describes instructional practices in PK-12 mathematics education that have attained critical gravity in the teaching field but whose efficacy has not been thoroughly and systematically researched. Then, we formed flexible subgroups interested in researching specific instructional practices or activities in PK-12 settings: Number Talks, open routines, and adaptive teaching. Within and across our subgroups, we explored the construct of efficacy and the multitude of ways it can be defined and measured. Each subgroup set research goals and has gathered virtually since the conference to prepare for conversations with grant program officers.

Keywords: Instructional Activities and Practices, Research Methods

Our working group is excited to report considerable progress made at PME-NA 47. Building on our work at and since PME-NA 46, we worked toward the following goals:

- Welcome new participants, introduce the metaphor of Black Holes of research, and share examples that build on this working group's productivity from PME-NA 2024.
- Identify challenges to gaining access to and researching in PreK-12 settings and brainstorm strategies for addressing them.
- Determine the theoretical and conceptual layers of the under-researched instructional activities and practices, identifying commonalities, priorities for research, and appropriate research methods.
- Consider variations in teachers' interpretations and implementation of the activities and practices.
- Produce a one-page summary as a tool to begin conversations with a grant program officer as we look towards developing a grant proposal.

As described in the day-by-day report below, as we addressed each goal, we shifted flexibly between whole-group and small-group discussions. The small groups formed organically based

on instructional practices and activities of interest. Foci and members of the small groups shifted throughout the three days as a result of conversations within and across groups. By the conclusion of PME-NA 47, three defined subgroups had formed, each focused on one of the following activities or practices: Number Talks (Humphreys & Parker, 2015; Parrish, 2011), Which One Doesn't Belong? (Danielson, 2016), and Adaptive Teaching (e.g., Allen et al., 2013; Gallagher et al., 2022). These three subgroups have continued to meet separately since PME-NA 47 to further define relevant constructs, conduct preliminary research, and strategize for grant applications. The whole group has also convened at several points to discuss common issues, consider points of intersection with future grant applications, and ensure connectedness across our approaches even while we pursue parallel avenues. We aim to use these opportunities to develop a coherent program of research that each grant and study can address.

Day 1: Orienting to the Metaphor and Forming Initial Groups

The first day of our working group focused on orienting new members to the group and to the metaphor of a Black Hole of research in mathematics education. Following introductions of existing members and new participants, Gabriel Matney provided background on the metaphor and how and why he created it (as first described in Matney et al. [2020]). Gabriel began by posing a question to our group: When, where, and how do research and instructional practice intersect? Gabriel and his colleagues had been doing Number Talks (Humphreys & Parker, 2015; Parrish, 2011) as practitioners of mathematics teaching for many years. When asked by one of their partnering districts to share research articles about Number Talks' efficacy with K-12 students, they believed that it would be easy to produce the evidence. Gabriel told the district he would have the articles to them by next week.

However, this led to a year-long peer-reviewed manuscript search across 17 databases, 576 unique articles, and only one article that provided efficacy evidence about Number Talks with K-12 students. As Gabriel and his colleagues reflected on this, they realized that Number Talks, which are a positive and meaningful instructional practice, were not a "hole" of knowledge. Number Talks has developed a large gravity in the teaching field because of its value to so many practitioners. Furthermore, the practice itself uses many elements of teaching, such as discourse, questioning, and number sense that have been researched, but the instructional practice itself has not. Hence, it was within this research setting that the Black Holes of research metaphor was born. Number Talks had attained a critical gravity in the field, like a Black Hole. Although the efficacy of the practice remained unresearched, there was other research pointing to its value, as the accretion disk of a Black Hole reveals to all that it is there.

Challenged by these circumstances, Gabriel began to work with his colleagues to think of the things in research that have garnered gravitational pull in the mathematics education field, and the Black Holes paper (and metaphor) provided a way to share that same challenge with others. He then shared several questions about Number Talks that remain unclear, and that could be asked of many other instructional practices and educational phenomena, including: What are the variations of Number Talks in the field? What are the purposes of these variations, and in what ways are they beneficial or not to students? What variations offer greater equity? What professional noticings and teacher moves contribute to making Number Talks effective, and how do we define, from research evidence, what makes a Number Talk highly effective? Gabriel concluded the presentation by sharing that Number Talks are not alone among educational and research phenomena. Other Black Holes exist. He shared his enthusiasm to explore with this working group what other Black Holes were out there and to figure out how to illuminate them.

Since the initial publication of Matney et al.'s (2020) literature review, researchers have

begun to shed light on the case of Number Talks. Dawn Woods shared about the work she has been doing as a result of her National Science Foundation (NSF) CAREER grant entitled *Sparking "Number Talks" to Strengthen Mathematical Identities.* This is a five-year participatory research project where we are identifying the funds of knowledge and the funds of identity that students, families, and communities bring to mathematics learning spaces. Then, teachers use the information to design Number Talks that may impact positive mathematical identity development. Early findings are showing that teachers are using Number Talks to highlight family rituals, play situations, and the world around them to give students moments to shine as they share the mathematics that is relevant to them. Further, student self-portraits are showing evidence of productive mathematical dispositions and other identity elements related to productive mathematical identity.

As an example of another Black Hole that has been identified but not yet systematically researched, Sarah Hartman shared about the instructional practice of adaptive teaching. The black hole metaphor aids in conceptualizing the complex nature of adaptive teaching, as it is not well conceptualized, and there are many literature bases that inform our current understanding of the skill of adaptability. Following a composite view of adaptive teachers presented by Randi (2022), Sarah discussed a mathematics education-specific conceptualization of related literature fields. The conceptualization involved a tetrahedral model where each edge represented the supporting competencies adaptive teachers need to be adaptive, faces of adaptive action that are further supported by the edges, and vertices that represent boundary navigation in the classroom. In McMillan and Jess's (2021) discussion of boundary navigation in the classroom setting, they describe three types of boundaries teachers must navigate: Individual boundaries, environmental boundaries, and task-related boundaries. Sarah discussed these related literature bases and explained a conceptualization of the literature informing adaptive teaching. Sarah concluded this session by answering any questions attendees of the working group had about adaptive teaching.

Following these examples of activities and practices to which the metaphor applies, we invited participants to form subgroups according to common research interests. To form these groups, we first brainstormed as a whole group about different areas we were interested in exploring. Resulting from this brainstorm, we decided that there were four distinct groups of interest and expertise in the group of attendees. As such. four groups formed around these initial foci (see Figure 1): Number Talks, open routines, content, and adaptive teaching.

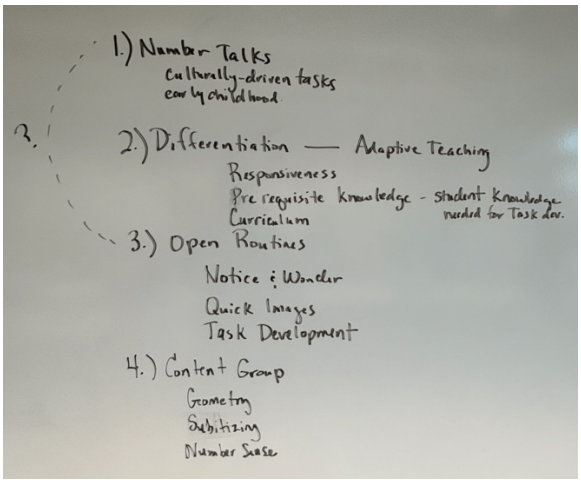

Figure 1: Initial Formations of Small Groups

After the first day, the open routines group merged with the Number Talks group because they only had two members. The Number Talks group began by discussing constructs related to efficacy, specifically how to measure whether and how Number Talks work as an instructional practice. We discussed constructs such as agency and elicitation that could provide insight into how Number Talks work as an instructional routine.

The content-focused group began by discussing the need to understand instructional routines and activities' impact on K-12 students' mathematical thinking, mathematical knowledge, and mathematical problem-solving ability. The group further discussed teachers' (in-service and preservice) development of mathematical pedagogical content knowledge related to the ambitious goal of having mathematically proficient students with prowess in these three domains: mathematical thinking, mathematical knowledge, and mathematical problem-solving ability. Following these discussions, the content subgroup agreed that the broader conversation should be narrowed to begin with research for a particular routine. The routine of main interest was Which One Doesn't Belong? (WODB), an activity popularized by Danielson (2016). In a WODB activity, learners are presented with images of four mathematically interesting items and asked to choose which one does not belong and why. All of the four items can be justified in multiple ways. This conversation spurred the content group's eventual merger with the open routines group to further work on WODB research.

The adaptive teaching group began by discussing different aspects of adaptive teaching we could explore. To get the group started, Sarah compiled a list of adaptive practices discussed in the literature. From this list, the group began working to understand what adaptive teaching is in the moment, what adaptive teaching is during planning, and the specific aspects of such processes. Using the group's varied expertise areas, a variety of ideas emerged, including cognitively demanding tasks, differences in adaptive teaching in elementary, secondary, and higher education levels, as well as differences in adaptive teaching with novice or veteran teachers. Afterwards, the group decided that a more specific aim was necessary to begin investigating adaptive teaching, and the group discussed what data could be collected and how adaptive teaching could be measured within some of the instructional routines that were presented previously (number talks and open routines).

Day 2: Fleshing out the Multi-Faceted Construct of Efficacy

To begin our second day, Gina Kling and her colleague Sarah Larison shared about their current research on the Black Hole surrounding the "How Many?" routine (Danielson, 2018). In the How Many routine, the class is presented with an image of a carefully curated collection of dice, dominoes, or other real-world objects, and is simply asked to describe how many they see (see Figure 2). Because of the open nature of the prompt, the task offers multiple entry points (National Council of Teachers of Mathematics [NCTM], 2014), as students can reasonably respond with the number of colors, the number of dice, or the number of dots, the latter of which offers opportunities for rich conversations of computational strategies. For example, for the first image in Figure 1, some children might begin with counting by 1s, skip counting, or combining the addends in order as they move across the image. But others might utilize helpful features of the structure, and attend to the double facts of 2 + 2 and 3 + 3 first, or even combine 2s and 3s to make 5s, and then 5s to make 10s. As students interact with the image and share their strategies with the class, an opportunity to assimilate more efficient strategies invented by their peers arises (Vygotsky, 1978).

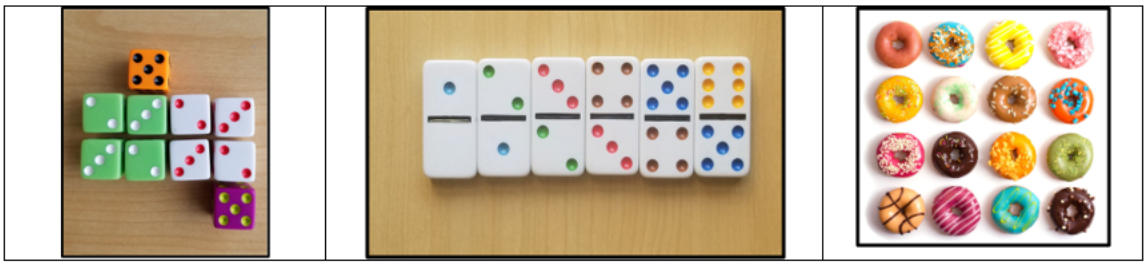

Figure 2: "How Many" Images from https://multiplicitylab.northwestern.edu/

Gina and Sarah shared the results of a recent study in which a three-week, nine-lesson How Many interventions in second and third grade produced statistically significant growth in student fluency as defined by flexibility, accuracy, efficiency, and appropriate strategy use (National Research Council [NRC], 2001). Despite the brevity of the intervention, the results of the study yield both practical implications in terms of a ready-to-use How Many curriculum and scholarly implications in terms of the introduction of a fluency framework that can measure fluency in the context of multiple addends, something lacking in the field. In particular, the latter might help address an outstanding question of the Black Holes Working Group—how might we measure the efficacy of a number sense routine?

Following the sharing of this example, given the focus of our group on systematically researching the *efficacy* of instructional practices and activities in PK-12 settings, it was critical to discuss what efficacy can actually mean. To frame our efforts, Sarah Hartman shared an overview of the family resemblance approach. The Family Resemblance Approach (FRA) (Dagher & Erduran, 2016) is a set-theoretic framework of the nature of science that uses the idea of overlapping similarities to describe how things are related. The goal of using this approach was to acknowledge the features of efficacy across each subgroup that could be used to create a common set of characteristics to study efficacy, which ultimately allowed us to contemplate defining and operationalizing efficacy.

To begin our discussion of efficacy, we returned to our subgroups, prefacing with a brief description of each one so that new members could decide where they might want to connect. Because the content-focused group had pivoted to talk about content with the context of open routines, the original members of the open routines group shifted to join them. This expanded open routines group identified several key properties of efficacy common across these instruction practices. First of all, we felt it was necessary that all students have access to engage meaningfully with the routine. In particular, the visual nature of some of our routines of interest, such as WODB and How Many, likely increases the accessibility of the routine. Secondly, this engagement is collective; that is, it is a social activity where students have opportunities to pick up on each other's thinking. This raised an interesting dimension to measuring efficacy, thinking about the collective growth of the class as a result of engaging in the routine as compared to the individual growth at the student level. We also considered efficacy in terms of facets that are valued within the mathematics education community but not necessarily at a policy level (e.g., agency, access, and ownership) as well as measures that are typically of more concern to administrators and policymakers (straightforward concept and skill assessments).

The number talks subgroup defined efficacy as the extent to which sustained participation in Number Talks supported students' mathematical development and engagement over time. The subgroup outlined a proposed design that followed the same cohort of third- and fourth-grade

students for two years and compared classrooms implementing Number Talks with business-as-usual (BAU) classrooms. The conceptual framing centered on three interconnected constructs: number sense, mathematical identity, and agency/engagement. The subgroup noted that classroom interactions during Number Talks—particularly teacher elicitation practices and student participation—were expected to support power shifts, increase points of engagement, and strengthen students' identities as mathematical thinkers. Efficacy was discussed in terms of both proximal and distal outcomes. Proximal measures focused on in-the-moment features of the Number Talk, including students' engagement, participation, and teacher–student interactions. Distal measures addressed longer-term learning outcomes, such as whole-number and fraction development, estimation, and mathematical identity, using established assessments, identity tasks, and stimulated-recall interviews. Overall, the subgroup framed efficacy as growth in both mathematical understanding and students' agency, engagement, and mathematical identity, highlighting the cognitive and affective outcomes associated with sustained participation in Number Talks.

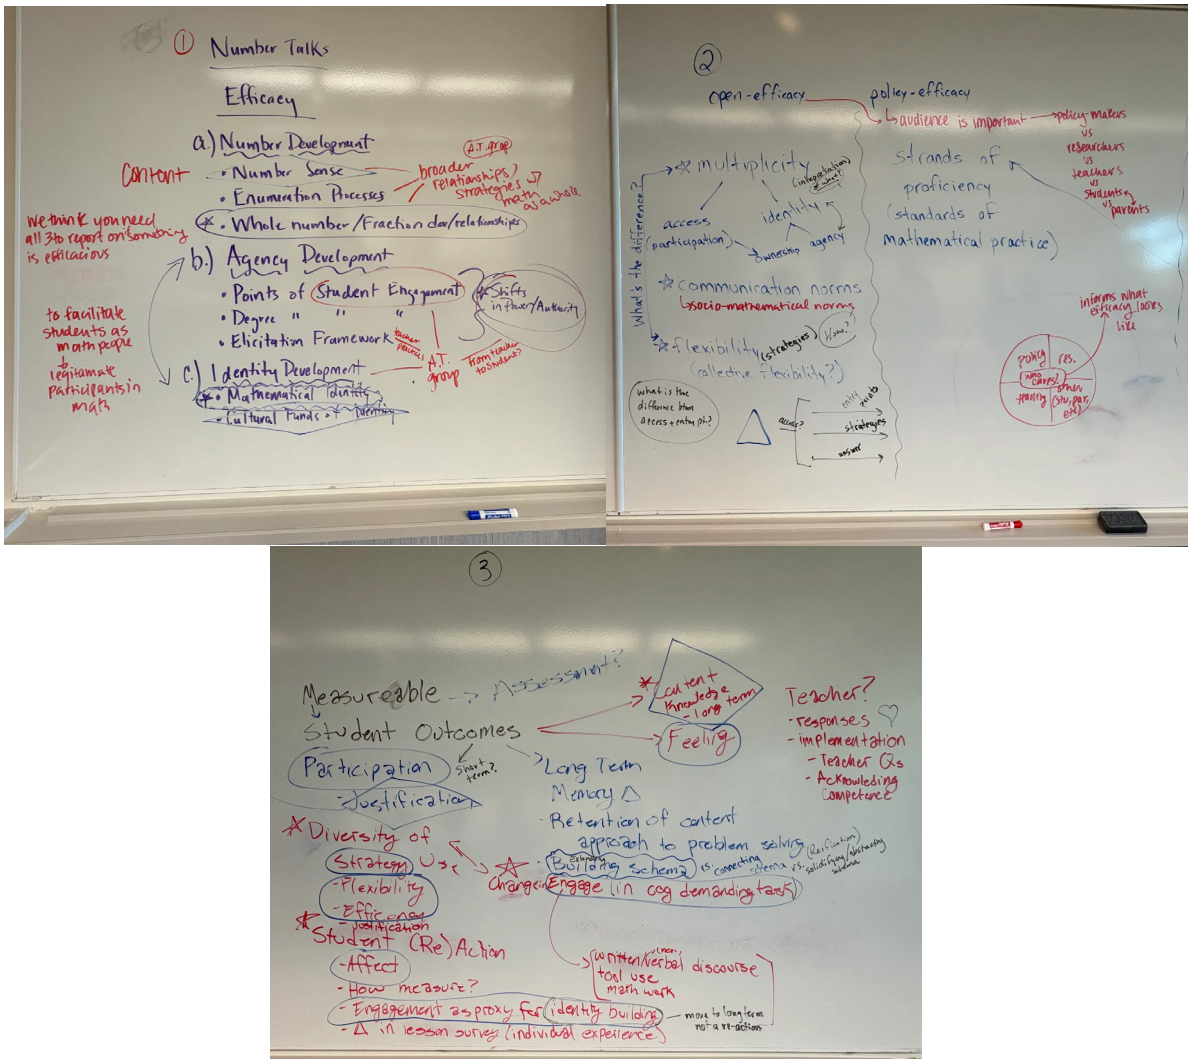

Figure 3: Whiteboard Recording of Efficacy Discussions

In the adaptive teaching subgroup, discussions of efficacy revolved around measurable outcomes, student outcomes in the form of content and affect, and teacher outcomes. For example, student outcomes included participation, justification, long term memory, retention of content, building schema, engagement, approaches to problem solving, diversity of strategy use with flexibility and efficiency, and student action and reaction. Efficacy for teachers and outcomes included attitude changes, responses, and implementation. Overwhelmingly, the adaptive teaching subgroup focused primarily on measurable student outcomes and who the audience is when discussing efficacy. For example, what is important and makes something efficacious for policy-makers is different from researchers, teachers, students, or parents.

Each subgroup recorded highlights of their own on the room's whiteboard, then rotated to read and comment on the other groups' thinking (see Figure 3). Looking across the reflections of the different groups, themes of efficacy in terms of student dispositions and student mathematical competency emerged. We felt that student agency and mathematical identity could be positively impacted by these activities, such as Number Talks, open routines, and through adaptive teaching, particularly as mathematical power and authority in the classroom is shared and students are seen as legitimate participants in mathematics. Pairing with these affective traits are considerations of gains in mathematical competency. Efficacy through this lens may be hallmarked by flexibility and efficiency in thinking, diversity in strategy use, and, in general, behaviors consistent with those described by the Strands of Mathematical Proficiency (NRC, 2001) and the Standards for Mathematical Practice (NGA & CCSSO, 2010).

Day 3: Drafting One-Pagers

For our final meeting, each subgroup met to further refine its focus, set specific goals, and draft one-page summaries to use in seeking funding opportunities. Beth MacDonald provided each group with a template for an NSF one-page narrative. This provided attendees from Days 1 and 2 who could not attend Day 3 an opportunity to contribute to the continued work and contribution towards a one-page narrative of a grant application. The one-page narrative allowed some groups an opportunity to explicate what they wanted to examine, their problem statement, and how the study they want to conduct will broadly impact society and intellectual merit in our field.

On the final day of our meeting, the content-focused/open routines group decided on a focus of one open routine in particular: Which One Doesn't Belong (WODB)? In keeping with the idea that the metaphor of a Black Hole involves a critical gravity that has attracted practitioners to a practice, we noted that WODB's critical gravity can be clearly established through its pervasive presence online (#WODB) and increasing inclusion in published curricula. The activity is also used widely across grades PK-12. Furthermore, WODB has a defined structure that is conducive to identifying instances of it, making it an appealing choice for a first routine to explore. As an initial research question, we decided to seek out examples of WODB as enacted in order to describe how teachers and students are engaging in WODB and begin to identify variations. We aimed to use this first question to build a foundation for researching how variations in implementation impact the efficacy of the routine.

The adaptive teaching subgroup created an outline for a one-page proposal. This began by identifying open questions in the field of adaptive teaching, such as how preservice teachers learn about differentiation and adaptive practices, and how to support their learning in those areas. Another question that was generated is how differentiation and adaptive practices are enacted. Furthermore, the group contemplated working towards a professional development

aimed at the enactment of adaptive teaching and outcomes for students. Finally, some draft research questions were created focusing on how teachers adapt and the impact of adaptations.

All work over the course of the three days was documented on our website (https://blackholesofmathematics.wordpress.com/, see "Group Meetings").

Continued Work

Following PME-NA, each subgroup has met to continue its work. The Number Talks group met four times since the PME-NA meeting. In this time, we have explored several funding agencies, determined the breadth of the work on Number Talks in the mathematics education field, and brought on people with expertise to discuss the means of using particular tools and exploring phenomena tangential to Number Talk routines. From this, we settled on the NSF STEM K-12 funding solicitation. The remainder of this spring and summer semester, the group plans to use this information to begin to form a comprehensive problem statement, research focus, methods, a broader impact statement, and a statement delineating the intellectual merit we think this study will contribute to. Once we have a one-page narrative developed, we plan to meet with program officers (i.e., Eric Knuth, Margret Hjalmarson). This will provide us enough information for our subsequent working group meeting at PME-NA 48 to fully develop aspects of a grant narrative for this solicitation. By developing this narrative at the working group, our subgroup will better understand how to clearly articulate the program of research we plan to develop in relation to the proposed study.

The WODB subgroup–which formed from the original open routines and content-focused subgroups–is working on surveying existing WODB tasks in curricula and teacher-created materials to identify variations in task design and suggestions for implementation. We also met with author Christopher Danielson (who formalized and popularized WODB) to gain his perspective on WODB task design and how we can describe and assess the efficacious outcomes that result from interaction with and discussion of a WODB task. Two interesting ways of thinking about the efficacy of WODB were defining learning as "having new questions to ask" and whether a task prompts the conversation the designer wants it to prompt. As we work to organize the features and variations of WODB as designed, our next steps are to identify classrooms in which to conduct pilot studies to understand how these variations play out in enactment (and what additional variations arise in enactment). With these findings in hand, we plan to seek grant support to support a more comprehensive study.

The adaptive teaching subgroup is currently focused on investigating where and how adaptive teaching occurs when enacting a number talk or an open task, such as WODB. The adaptive teaching group is focused on a different area of these open routines, adaptive enactment. Adaptive enactment is a central term we use to describe decision-making across various practices. Rather than focusing explicitly on what the efficacy of a practice is, we are working to understand what it means to enact a routine efficaciously. This complements other subgroups' work by focusing on different aspects of the Number Talk routine and the WODB routine. Next steps for the group involve collaborating with other groups to begin conceptualizing data collection to accomplish this goal and reading relevant literature on this subject.

The working group as a whole continues to be in contact virtually and in person as we plan future working group sessions, share progress, and consider ways to connect our work. We are proudly a group that is productive, inclusive, and joyful–three adjectives that, perhaps unsurprisingly, also apply to the practices and activities on which our research seeks to shed light.

A NEW WORKING GROUP: SUPPORTING TEACHER EDUCATORS WITH IMPLEMENTING, RESEARCHING, AND COACHING BUILDING THINKING CLASSROOMS

Matthew Melville
Purdue University Fort Wayne
mdmelvil@pfw.edu

Betsy Berry
Purdue University Fort Wayne
sberry@pfw.edu

Melissa Southerland
Purdue University Fort Wayne
reifma01@pfw.edu

This working group seeks to produce innovative ways to support teachers' implementation of 'Building Thinking Classrooms' at the university and K-12 levels. Communities of learners will be created for the following three main groups: Research, Coaching, and Implementation.

Keywords: Professional Development, Preservice Teacher Education, Classroom Discourse, Problem Solving

Introduction

Since it was first introduced to the mathematics education community, *Building Thinking Classrooms* (BTC) (Liljedahl, 2021) continues to grow in relevance among teachers and teacher educators across North America. We see this growth in regional conferences, professional learning programs, and learning communities across social media platforms. The relevance of this initiative has grown so much that the first annual International Building Thinking Classrooms Conference was held in Indianapolis in 2023. While BTC is a research-based initiative, the resources for teachers are mainly limited to the book and online forums for sharing ideas. For teachers to successfully implement, critique, and supplement these practices, guidance is needed to support their work. Our goal as mathematics teachers and mathematics teacher educators is to study how the practices and their implementation are supporting effective teaching and learning. Our aim is to support teachers to draw on the practices, along with other research-based initiatives that align with increasing student thinking in the classroom, as they make professional decisions in their classroom.

The authors of this working group have engaged in various initiatives centered around BTC. One author has created an Instructional Circle (Melville, 2022) to provide personalized and deprivatized feedback to teachers as they implement BTC. There are three stages to implementation of BTC that become more difficult to implement in a classroom (Liljedahl, 2016). The instructional circle is a form of professional learning where teachers can find support from experienced teachers and knowledgeable others about ways they can improve their instructional practices. Another author developed an initiative with a local school district to provide instruction and materials for teachers wanting to implement BTC but lacking the support or materials to be successful. Lastly, one author's team is engaging in an initiative looking at specific aspects of BTC including task writing and "thin slicing" and how teachers are utilizing them in their implementation of BTC (Frazee et al., 2023).

As mathematics teachers and mathematics teacher educators, we feel it is worthwhile to support the implementation of BTCs in a variety of contexts. This instructional practice supports ambitious teaching as defined in *Principles to Actions: Ensuring Mathematical Success for All* (National Council of Teachers of Mathematics [NCTM], 2014). The creators of BTC also understand professional learning principles that state incremental changes to teacher practices are

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

more sustainable long-term than sudden transformational professional developments (Otten et al., 2022).

Goals of the Working Group

The goals of this working group are two-fold. First, we want to serve as a forum for authors and participants to share a variety of research projects centered around *Building Thinking Classrooms* (Liljedahl, 2021). This will inform the conversations about how to create a more effective implementation and support structure for teachers using this instructional practice in both K-12 and university levels. Second, instructional circles (Melville, 2022) will be created for the participants of the working group to form professional learning communities for support around their specific interest with BTC beyond this conference. Specifically, these contexts may include using BTC in math content courses, math methods courses, in-service professional learning, and ways in which research projects can be designed to study various aspects of these settings. We believe that these instructional circles will be a valuable resource as we implement and study the effects of BTC on student learning and teacher education and the growth of mathematics teacher educators.

We have had a previous iteration of this working group that has since been dissolved. However, with the interest and outreach from previous attendees, we feel that there are sufficient need and interest for us to hold this working group again. Changes that we will make are a monthly newsletter and meeting for attendees who are interested and need further support. Then, in future iterations of the working group, we will be able to integrate new members and allow space to delve deeper into different problems of practice and research instead of remaining at a surface level.

Organization and Presentation Plan

The first session will start with presentations from the authors about what they are currently doing regarding coaching, implementing, and teaching BTC in methods courses and professional learning contexts. The authors alone have a variety of initiatives around BTC. One example is that BTC is being studied as a vehicle for task assessment and professional learning of teachers around planning (Frazee et al., 2023). Another example is through an Instructional Circle (Melville, 2022) the first author gave personalized feedback to teachers as they implemented BTC. The last initiative studies how BTC is being used in a more traditional professional learning course for teachers who are currently implementing or would like to implement these instructional strategies.

The second session will include reports from non-author participants about their current initiatives that utilize BTC or that could benefit from using BTC. These participants will volunteer during the first session for this activity. The second session will end with forming break out groups according to participants' interest in utilizing BTC (i.e., math content classrooms, math methods classrooms, professional learning settings, or researching the effects of BTC in these other contexts).

The third session will continue with the breakout groups for the different contexts that participants are interested in utilizing BTC. During these breakout sessions, we plan to help organize the participants into instructional circles to provide support and fresh ideas to implement or study BTC in different settings. This session will also include each group sharing their current ideas and goals with the whole group.

In our eighth year as a working group, we will continue to discuss current recommendations and research for teaching and learning with data investigations with a focus on cross-disciplinary contexts, the role of artificial intelligence, and political implications in the current state of STEM education research. We will also foster dialogue around ongoing and future possible collaborations around researching the teaching and learning of data investigations. We invite returning and new members to join us in collaboratively researching how to best support meaningful data investigations across disciplinary contexts and boundaries.

Keywords: Data Analysis and Statistics, Integrated STEM / STEAM

Background

Our working group's collaboration on examining teaching and learning statistics and data science concepts and practices through data investigations has led us to key emergent questions over the years. For example, as we considered the interdisciplinary nature of data investigation, we encountered the issue of disentangling the notion of content and context. What we consider as content may not be content from other disciplinary points of view. More recently, the emergence of artificial intelligence and machine learning (AI/ML) is reshaping what data investigation means, moving beyond traditional statistical analysis. This change also prompted us to rethink teaching and learning with data investigation with emergent data investigation tools and methods. In addition, over the past year, members of the working group became keenly aware of the changing landscape of research on teaching and learning, driven by changes in policies and the political climate, which drives our considerations for meeting in 2026.

Theoretical Background

While considering the current issues shaping our work, the working group continues to focus on integrating existing recommendations for teaching statistics and data science in K-12 education (Bargagliotti et al., 2020; NCTM, NSTA, ASA, NCSS, & CSTA, 2024). Most real-world data investigations draw from concepts, knowledge, and practices beyond mathematics and statistics. Consequently, this working group seeks to connect projects spanning diverse disciplines and frameworks for data investigations (Lee et al., 2022; Wong et al., 2025). Notably, we include socioscientific (Zeidler et al., 2019; Smucker et al., 2024), sociopolitical (Miller et

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

al., 2024; Casey et al., 2022), and data science and AI/ML (Data Science 4 Everyone, 2025; Sanusi et al., 2023; Tseng et al., 2021; Touretzky et al., 2025) contexts for data investigation.

Organization of Working Group Activities

Over the three sessions at PME-NA, we plan to engage with participants through discussions, brief demos, and activities around the above mentioned three key emergent themes detailed below (Figure 1).

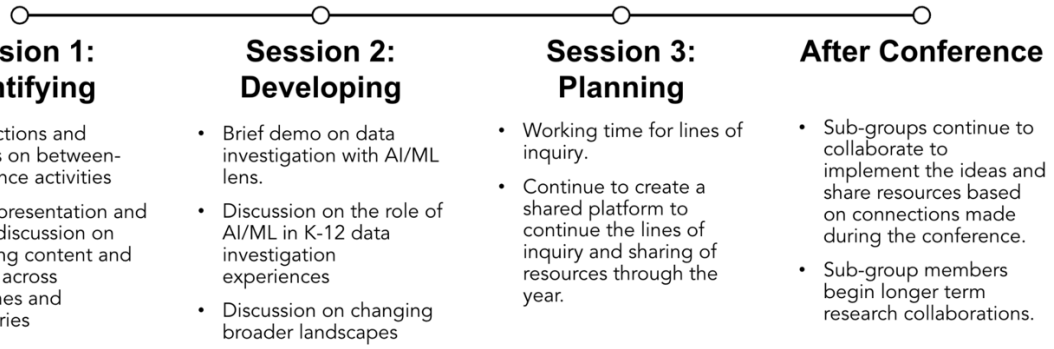

Figure 1: Outline of Activities for PME-NA Working Group Sessions

1. Theorizing Content and Context Across Disciplines and Boundaries

One of the key features of teaching and learning with data investigation is the consideration of context. As the working group delved into conceptualizing data investigation, we repeatedly encountered conceptual ambiguity between the methods and approaches of data investigation (i.e., content) and the issues or topics the data investigation aims to illuminate (i.e., context). From the perspective of another discipline (e.g., social studies education), the context of data investigation is the content that defines its discipline's learning. We will further disentangle this conceptual ambiguity by considering available frameworks in multidisciplinary settings.

2. The Role of AI/ML in Data Investigation

We position AI/ML as a lens for examining data practices in K-12 mathematics and statistics classrooms and in teacher education. To spark this discussion, working group participants will engage in a brief demo on training and testing simple ML models. We introduce web-based ML models that do not require students to write code but instead foreground data-handling practices and core ML concepts. We will also explore how ML-based investigations could reshape core data practices and instructional approaches in K-12 settings.

3. Statistics and Data Science Education in a Broader Landscape

Our work is constantly shaped by broader policy shifts and technological developments. Inconsistent policy regarding K-12 data science curricula and the rise of generative AI have raised concerns about ethical use, misinformation, and learning impacts. At the same time, our research activities are impacted by grant terminations, limits to federal data access, and increasing political tensions. We aim to exchange our perspectives on these pressing issues.

As momentum continues to grow, the group actively welcomes new members interested in advancing teaching and learning with data investigations across disciplinary contexts and boundaries. The working group activities are organized so that new participants can get an overview of the group's history and prior work before participating in discussions on the current focus around data investigations.

The Teaching and Learning with Data Investigation Working Group continues to be a source of community and production. With many projects finished, near completion, and underway, this group is very active. Herein we summarize the background of the group, activities at the 2025 PME-NA Conference, and current and future activities.

Keywords: Data Analysis and Statistics, Integrated STEM / STEAM

Background

This working group, which first convened in 2019 at PME-NA, has steadily sharpened its focus and expanded membership each year. Initially, the group explored a newly published framework for meaningful statistical learning environments (Ben-Zvi et al., 2018), sparking discussions on different design aspects. In 2020, the focus shifted to statistics education across boundaries, bringing together scholars from the US and Mexico with bilingual sessions in Spanish and English. By 2021, the group began examining the role of data science education in statistics and mathematics curricula. In 2022, attention turned to the growing movement to integrate data science into K-12 education, emphasizing data investigations as a means to address broader data literacy needs rather than treating statistics and data science as separate fields (Education Development Center, 2015; Lee et al., 2022). Additionally, work was done by a subgroup to create a publication for the practitioner journal *Mathematics Teacher: Learning and Teaching PK-12* to consider how to translate the 5 practices for orchestrating productive discourse (Smith & Stein, 2018) to teaching statistics in the mathematics classroom (Smucker et al., 2024). In 2023, the group identified investigations of socio-scientific and socio-political data as productive vehicles for inter- and transdisciplinary learning. In 2024, subsets of our working group continued to meet throughout the year to work on a conference grant proposal, a book chapter for the *Mexican Society for Research in Mathematics Educatio*n (Weiland et al., in press), a Statistical 5 Practices lesson plan and activity for *NCTM Illuminations*, various *ZDM* journal article submissions for a Special Issue one of our members is helping to edit, and to plan for the 2025 PME-NA conference. In 2025, we welcomed several new members to this working group at Penn State University and continued ongoing work from the previous year.

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

Overview of the Working Group Activities

At the 2025 PME-NA conference, we had three main goals for the working group: (1) to continue to explore how the context of data (its collection, organization, and social relevance) intersects with the context of the students, their experiences, curricular goals, local settings, and disciplinary perspectives in mathematics, social studies, and sciences, (2) examine the affordances and challenges of transdisciplinary data investigations across instructional contexts, and (3) investigate the role of artificial intelligence in data science education, particularly in fostering students' critical evaluation of AI-generated artifacts. Based on these goals we planned interactive and engaging activities across the three days of the conference. For each session, we had around 20 people participate each day. Summaries of the activities are described by day, in the sections that follow.

Day 1

The first day began with a data talk led by Franziska Peterson, where participants investigated information from the Pennsylvania *Climate Impacts Assessment.* This task provided an opportunity to quickly engage in conversation regarding our Working Group theme of Transdisciplinary Data Investigations connected to the context of the PME-NA 2025 conference location. After the data talk and group introductions, in person participants gathered around poster papers and online participants joined a Zoom breakout room to discuss questions our group felt were salient to the state of the field of statistics and data science education:

- What contextual examples from your experience and/or work provide opportunities for transdisciplinary data investigations?
- What are the challenges to enacting or providing transdisciplinary data investigation experiences?
- What role can AI play in transdisciplinary data investigation experiences? Have you used AI as a tool for working with data? If so, how?

Participants circulated around these questions and shared their experience with these topics and which they were interested in delving into more deeply (see Figure 1 for poster examples). Regarding the first question, participants highlighted several real-world contexts that offer strong opportunities for transdisciplinary data investigations. These included traffic stop data, school records, and school funding data, with two members emphasizing the depth and complexity required to meaningfully analyze these data. Others shared experiences with place-based learning focused on climate change, particularly examining environmental factors and equity issues within local communities, as well as youth participatory action research in which students engaged in graphical interpretation of data to investigate and act on issues relevant to their communities. Across examples, the common theme was using authentic, socially relevant data to connect multiple disciplines and uncover deeper systemic patterns.

The discussion around the second question revealed several key challenges to enacting transdisciplinary data investigations. Limited access to technology restricts the ability to work with large, real-world datasets, and many educators lack familiarity with data visualization tools. Addressing controversial topics—such as race and racism—can also be challenging. Significant planning time is required to design and implement meaningful data investigations, raising questions about how to better support teachers. Gaps in contextual knowledge can shape how data is interpreted, prompting the need for strategies to help teachers build relevant background knowledge. Finally, the siloed structure of STEM education presents systemic barriers, as schools often lack structures that support collaboration across disciplines.

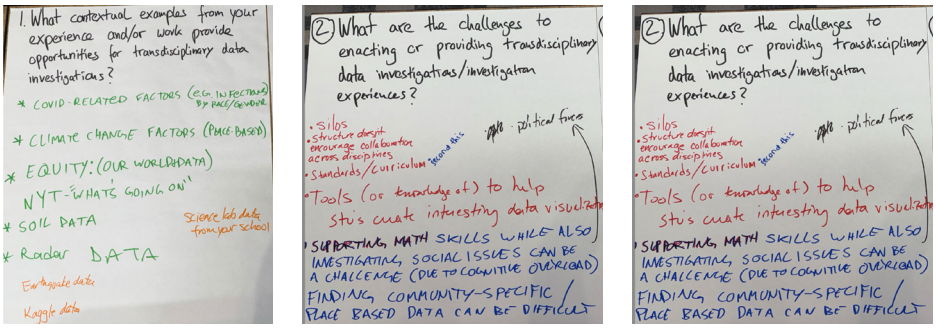

Figure 1: Day 1 Discussion Group Poster Examples

Ideas shared around the third question included using AI to clean and analyze datasets, generate Python code for statistical investigations, and locate useful datasets for instructional purposes. AI can streamline technical processes and expand access to more complex analyses, including practices already common in university settings. However, effective use requires significant background knowledge, raising questions about how to prepare both teachers and students to use AI thoughtfully and effectively. Ethical concerns around AI-generated analysis also remain important. Participants emphasized the need for lessons and resources that help students understand how AI works, ensuring it is used critically and responsibly rather than as a black box tool.

This activity verified that all participants were interested in thinking together about how to support students and teachers in these aspects of transdisciplinary data investigations, which we would continue to explore in a variety of ways throughout the conference working group sessions. Day 1 ended with confirmation that there was much interest in more deeply examining the affordances of two technologies (CODAP and AI) the next day, along with an invitation to share other research interests associated with data investigation.

Day 2

Travis Weiland began Day 2 with an introduction to data from the *American Community Survey* which could efficiently be examined via the Census Microdata Plug-in in *CODAP* (see Figure 2 below*).* We were asked while exploring to ask ourselves, "What is a question that would be interesting to investigate with this data?"

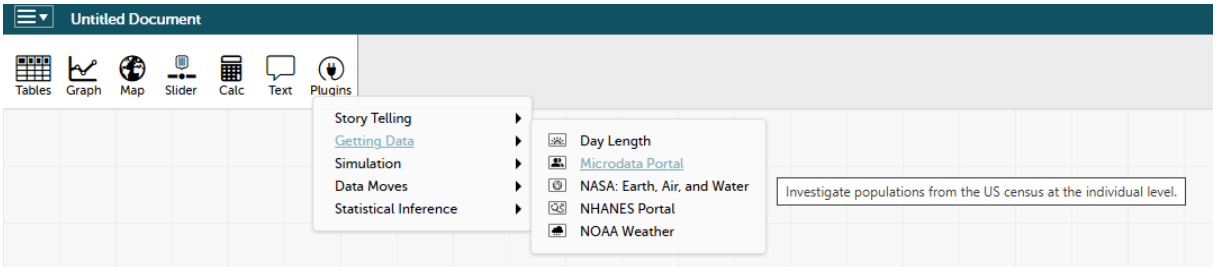

Figure 2: CODAP Microdata Portal

In addition to CODAP, the working group devoted considerable time to examining the affordances of other available technologies (e.g., Google Teachable Machine) and data source for teaching, learning, and research. Karie Smucker and Francisco Sepúlveda next shared an

overview of the forthcoming *NCTM Illuminations* lesson plan and activity, which utilizes this data and technology, which they have been developing with other working group members. Again, in order to facilitate reflection and conversation, participants shared some of their thoughts and reflections regarding these tasks via butcher paper (see Figure 3 below).

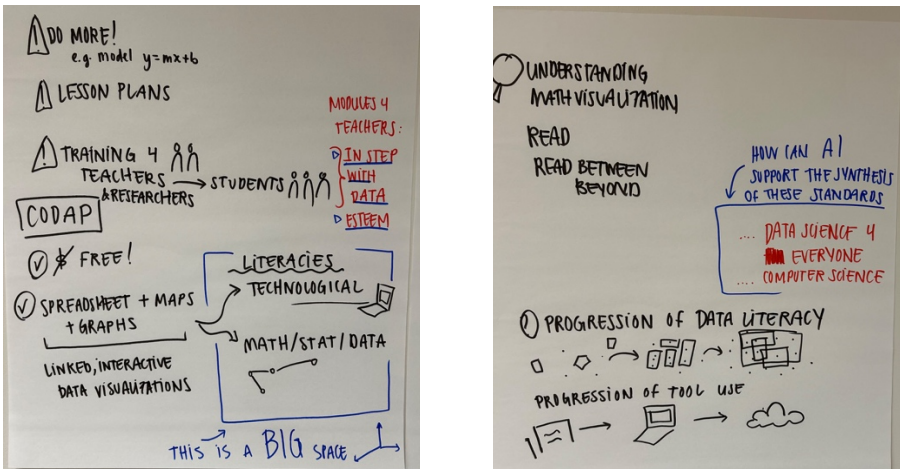

Figure 3: Day 2 CODAP Microportal Reflections

Figure 3 posters were generated by working group newcomers to visually represent their initial ideas about how CODAP microportals could be integrated into their current projects, curricula, and research contexts.

Finally, Day 2 ended with Sunghwan Byun leading the group through ways that he and his colleagues are utilizing AI prompt templates to support students and teachers in deepening their understanding of how to investigate data with R technology (see Figure 4 below).

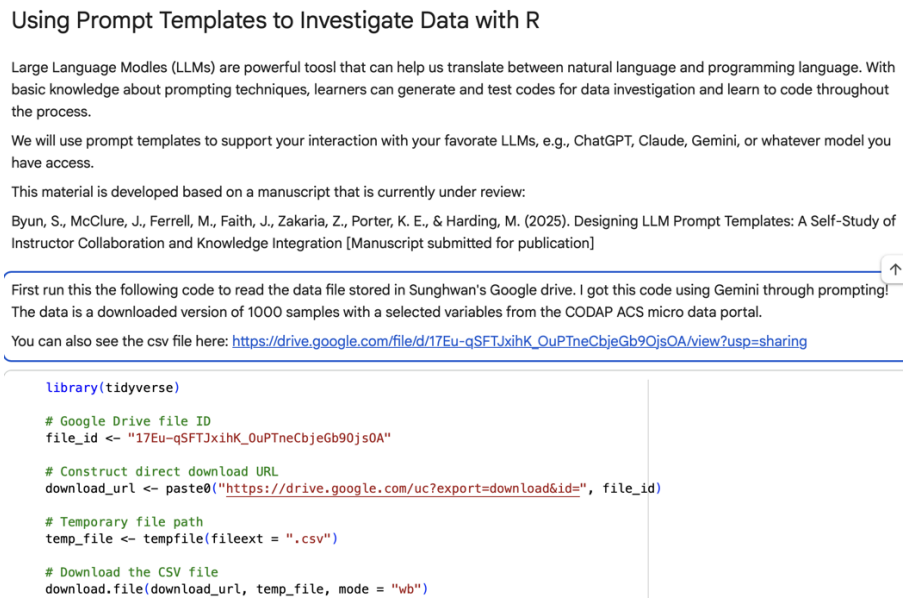

Figure 4: Presentation by Sunghwan Byun Regarding Using AI and R for Data Investigation

Day 3

Day 3 began with Anthony Fernandes demonstrating instructional resources and research findings associated with the *Statistical Investigations of Systemic Racism* project (see Figure 5 below). This led to rich discussion regarding strategies to support students and teachers in exploring data and discussions around controversial topics like policing of traffic stops in the U.S. The goal of the project is to prepare future teachers to develop their statistical understanding and awareness of how racism acts as a system.

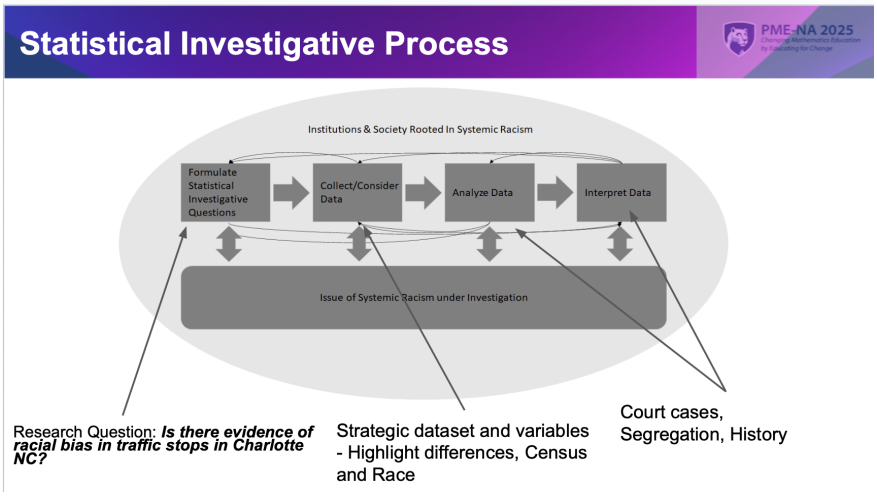

Figure 5: Screenshot from Statistical Investigations of Systemic Racism Project

Next, Mathew Beckman, from the PME-NA host institution highlighted research he is involved in associated with utilizing AI in support of teaching large (statistics) classes and the CAUSE community supported data science education researchers. Day 3 concluded with reflection on the many topics examined across the three days and discussion of collaborative 'next steps'. These reflective discussions set the stage for the post-conference working group activities outlined below.

Post-Conference Working Group Activities

After the 2025 PME-NA Conference, the Teaching and Learning with Data Investigation Working Group has continued to welcome new members and meet to coordinate research groups. In order to support this work, the working group leaders synthesized the ideas generated on day three of the conference into three key lines of inquiry, which are listed below:

1. Exploration of the conception and interface of context and content
2. Investigating how students make sense of non-traditional data visualizations
3. Investigating teaching and learning with CODAP and its design features

Each of these subgroups has met since the conference and their progress moving each theme forward is summarized below:

1) Context and Content

Eleven members met to discuss their conceptions around context and content. Given that we were approaching this topic from different experiences, we spent some time discussing our

thinking about content and context. For example, context involved the context of our work—with students, preservice teachers, and teachers, and also the context of the statistical investigations—climate and race. Some time was spent discussing how these contexts intersected with the content that was needed at a particular level, along with the use of the appropriate technology. We also discussed how defining context and content can be challenging when pursuing interdisciplinary investigations; for example, what is considered context from a statistical perspective may be the focus content for a science or social science teacher. In closing, we agreed to continue to meet to refine our definitions and think about possible common areas for collaboration, in particular the potential for working on a theoretical publication which considers these issues and began generating literature of related publications to share and discuss.

2) Non-traditional Data Visualizations

Seven interested members have met twice to discuss research interests and goals around the topic of the teaching and learning of data visualizations. The group has decided to start by conducting a systematic review of existing literature in this area in order to become familiar with the literature and to create a manuscript to report on the results of the review. Members have begun to identify other relevant reviews, possible research questions and possible boundaries for the search and are exploring possible keywords, databases and journals to review.

3) Teaching and Learning with CODAP

Eight members met and discussed possible common interests around the idea of investigating aspects of teaching and learning with CODAP. Group members' interests vary and are broad in scope, so the group is continuing to meet to identify possible overlap in interests for continued collaboration. Some potential areas for collaboration included seeking grant funding to expand the sampling tool for the American Community Survey CODAP microportal, developing tasks using the microportal for use with students, and potential study designs to investigate how students and/or teachers utilize CODAP to approach data investigations.

We have continued to meet in subgroups around these three areas, above, prepare this report, work on our 2026 proposal, complete the activities highlighted at the beginning of this report, and identify other areas of synergy. We are very excited and grateful to have such a collaborative and productive community of teachers, researchers, and teacher educators focused on moving our careers and our field forward.

wiest@unr.edu

Since 2018, the Gender and Sexuality Working Group has convened annually at PME-NA. The past 2 years, our focus has been on concealable stigmatized identities, culminating in the presentation and exploration of data last year from a study involving pre-service teachers that was conducted by the leadership team. Building on this study's findings, wherein many pre-service teachers questioned the need to consider gender and sexuality in mathematics teaching and learning, in this year's working group, we will explore the neutrality myth in mathematics education—that mathematics is unbiased, objective, and value-free—with a focus on gender and sexuality. During the working group sessions, participants will have the opportunity to explore how the neutrality myth impacts mathematics and mathematics education, both in terms of teaching/learning and research, through discussions and hands-on activities.

Keywords: Gender; LGBTQIA+; Equity, Inclusion, and Diversity

More than perhaps any other subject area, mathematics is associated with myths surrounding its purported neutrality. Arguments are made that mathematics is "just numbers" and "has one right answer," so it is not impacted by sociocultural factors that play a more obvious role in other subject areas, namely the humanities and social sciences (Ernest, 2021; Lue & O'Neal Turner, 2020). Scholars working in the diversity, equity, and inclusion spaces have questioned the presumed neutrality of mathematics, mathematics education, and mathematics education research, for decades (e.g., Burton, 1995; Ernest, 1998; Smith, 1994). However, due to the pervasive nature of this neutrality myth, there is pushback—from parents, teachers, administrators, and the general public—on inclusive pedagogical practices and topics such as social justice mathematics (Gómez Marchant et al., 2023; Mamolo & Pinto, 2015).

Theoretical Background

The neutrality of mathematics, with regard to gender and sexuality, has been challenged in the discipline of mathematics, in the field of mathematics education, and in mathematics education research (e.g., Frankenstein, 1983; Yankova, 2024). This challenge can be framed using Rands' (2009) four forms of gender education. Although Rands focuses on gender, these ideas can be equally applied to sexuality. The view of mathematics as neutral often leads to *gender-free* or *gender-blind education*, whereby it is believed that "gender can and should be ignored in educational contexts and … is irrelevant to education" (p. 425). However, sometimes the harmful impacts of mathematical neutrality (e.g., as Eurocentric or hegemonic) can be represented in *gender-stereotyped education*, where binary gender stereotypes are embedded within educational systems (e.g., implicit bias against girls in mathematics). Educators can work to counteract the previous two forms of education through *gender-sensitive education* or *gender-complex education*. In mathematics, gender-sensitive education could entail addressing issues of

gender in content or pedagogy directly, but often still adhering to the gender binary. In contrast, gender-complex education goes beyond the gender binary and addresses multiple intersecting levels of privilege and oppression. In mathematics, gender-complex education might entail questioning how gender is represented in mathematics problems in textbooks (e.g., Parise, 2021).

History and Goals of the Working Group

During the past two PME-NA conferences, the Gender and Sexuality Working Group (GSWG) concentrated on concealable stigmatized identities (CSIs; Hall et al., 2024; Piatek-Jimenez et al., 2025). In 2024, the focus of the GSWG sessions was intersectionality and CSIs. Participants delved into these topics, both generally and with respect to their own experiences, and hypothetical case studies reviewed during the sessions. Based on suggestions from participants at the GSWG sessions, the leadership team conducted a small research project in which they collected questionnaire data from 95 pre-service teachers in Australia, Canada, and the U.S. Specifically, participants were asked to consider how four CSIs—gender, sexual orientation, mental health, and socioeconomic status—impacted their own mathematics learning, as well as how these identities might influence their future students' mathematics learning.

During the 2025 GSWG sessions, initial findings from this study were shared as aggregate overviews and six case studies. Although nearly all questionnaire participants could readily provide examples of ways that mental health and socioeconomic status may play a role in mathematics education, a large proportion questioned how gender and/or sexual orientation would be relevant to mathematics teaching and learning. Sharing these findings led to discussions in the group about the study participants' views of mathematics as neutral, asocial, and competitive. After reflection, the leadership team determined that the conception of mathematics as neutral would be a worthwhile topic for further exploration in the 2026 GSWG.

Description of This Year's Working Group Sessions

The GSWG sessions will follow a three-part structure, where various aspects of mathematics education will be addressed with respect to the neutrality myth, focusing on gender and sexuality. In *Session 1*, the focus will be mathematics itself. Members of the leadership team will give a brief presentation to acquaint participants with the topic of neutrality in mathematics, as well as explain the impetus of this year's GSWG theme based on last year's group discussions. The remainder of the session will be devoted to small-group discussions regarding the reification of this myth in popular media and amongst the general public, with examples provided to analyze. *Session 2's* focus will be examining the neutrality of mathematics teaching and learning. Participants will be provided with practical hands-on examples of various types of mathematics problems (e.g., word problems) for analysis and discussion. For *Session 3*, the focus will then extend to challenging the neutrality of mathematics education research. We will share examples for analysis and facilitate discussions on future avenues of research. We anticipate that these discussions will lead to scholarly collaborations amongst the GSWG participants.

The Gender and Sexuality Working Group has convened at PME-NA each year since 2018. For the past two years, this working group has focused on the topics of intersectionality and concealable stigmatized identities (CSIs) in relation to gender and sexuality in mathematics education. During PME-NA 2025, the working group met and discussed data that were collected prior to the conference that related to pre-service teachers' experiences with and beliefs about the learning and teaching of mathematics in relation to their own and students' CSIs. Participants in the working group had the opportunity to explore and discuss both quantitative data and case studies.

Keywords: Gender; LGBTQIA+; Equity, Inclusion, and Diversity

History of the Working Group

The concept of the Gender and Sexuality Working Group emerged from conversations about equity in mathematics education during the 2017 PME-NA conference in Indianapolis, IN and the first official sessions were held during the 2018 PME-NA conference in Greenville, SC. Since then, the group has convened each year at PME-NA to support ongoing and important dialogue related to gender and sexuality in mathematics education. At these conferences, the working group leaders and participants addressed a range of topics, including theoretical and empirical work (Przybyla-Kuchek et al., 2022), conceptual and methodological approaches (Jackson et al., 2021), strategies for data collection (Ataide Pinheiro et al., 2023), and concealable stigmatized identities (CSIs; Hall et al., 2024; Piatek-Jimenez et al., 2025). This working group has consistently fostered an inclusive and supportive environment for graduate students and early-career scholars, offering spaces to present research, assume leadership roles, and collaborate with researchers from the United States, Canada, Brazil, and Australia.

Theoretical Underpinnings of This Working Group

Three theories form the foundation for the scholarly endeavors of this working group. *Intersectionality theory* (Crenshaw, 1989) is the understanding that social identities (e.g., gender, sexuality, race, social class) do not operate in individuals' lives independently but rather interact in meaningful ways in classrooms and other settings (Smooth, 2013). A second theory that explains educational phenomena and relates to this working group is *social identity theory* (Tajfel & Turner, 1979). The essence of this theory is that people tend to perceive themselves as being members of specific social identity groups and hold subjective beliefs about different groups and their relationships, which influences their perceptions and behavior (Ellemers & Haslam, 2012). Finally, *minority stress theory* is integral to this working group's efforts (Brooks, 1981). Through employing this theory, we acknowledge the role of the "excess stress burden that

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

places sexual and gender minority people at greater risk for negative health outcomes [e.g., mental health] compared with cisgender straight people" (Frost & Meyer, 2023, p. 2).

Progress Made During and In Between Conferences

During the Gender and Sexuality Working Group sessions at the 2024 PME-NA conference, discussions centered on the multiple identities that individuals bring with them to the classroom and the influence that these identities can play in mathematics teaching and learning. We explored the role of a variety of identities, but discussion homed in on concealable stigmatized identities. Although having concealable identities allows students to have more control over which identities they share with others, the choice to do so often engenders stress and can result in feelings of invisibility and exclusion when students with CSIs are unable to bring their entire selves to the classroom (Keblbeck et al., 2024; Vaccaro et al., 2024). Many questions arose during the working group sessions surrounding these topics, including the roles that teacher education programs could play in assisting K–12 teachers to better understand the intersectional identities of their future students and relationships between these identities and classroom teaching and learning.

Between the 2024 and 2025 conferences, the leadership team of the working group designed and carried out a study in which we collected data from 95 pre-service K–12 mathematics teachers on their own personal experiences with learning mathematics in terms of four specific CSIs (gender, sexual orientation, socioeconomic status, and mental health) and their perspectives on how those same four CSIs might affect the mathematics learning of their future students. The participants were enrolled in four different universities in three countries (the United States, Canada, and Australia). We brought our initial findings from this study, in the form of both quantitative results and case studies, to the 2025 working group sessions for the participants to discuss.

2025 Working Group Sessions and Efforts Made to Include Participants

During the 2025 working group sessions, our goal was to delve into conversations with the working group participants about pre-service teachers' experiences with and knowledge of the roles of CSIs in mathematics teaching and learning. By exploring both CSIs that are pertinent to the topic of this working group (i.e., gender and sexual orientation) and CSIs that are not the direct focus of this working group but are underexplored in mathematics education research (i.e., socioeconomic status and mental health) and are important identities that interact with gender and sexuality, we aimed to better understand students' intersectional experiences. Throughout the working group sessions, we found that the working group participants were able to more deeply analyze societal views of mathematics as a field, and of gender and sexuality in general and in relation to mathematics, by exploring these macro-level identities. A day-by-day breakdown of our 2025 working group sessions follows.

Session 1

During Session 1, we began by having each attendee, including the members of the leadership team, introduce themselves and their academic interest in topics related to gender and/or sexuality in mathematics education. Members of the leadership team then gave a 15-minute presentation to acquaint participants with the topics of intersectionality and CSIs, including the history of the concepts and examples from mathematics education research. We also shared the Wheel of Power and Privilege (see Figure 1) with the group. The remainder of the session was devoted to small-group discussions regarding participants' experiences with CSIs in their research on gender and sexuality, as well as in their teaching. Some other CSIs that

participants discussed included learning disabilities, motherhood within the context of being a scholar, and non-motherhood in contexts outside of academia.

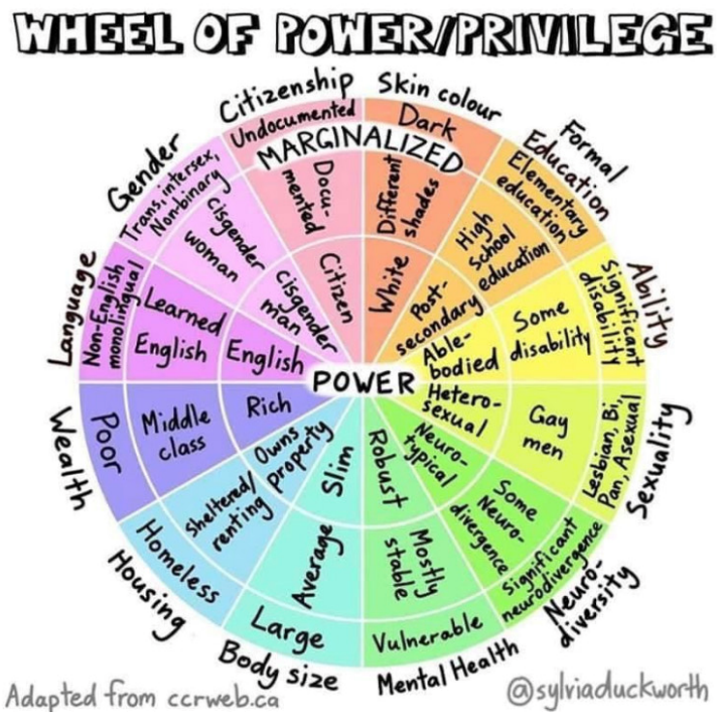

Figure 1: The Wheel of Power/Privilege (Duckworth, 2020)

Session 2

Session 2 began with a brief explanation of the data collection that was undertaken by the leadership team since the previous year's conference. The leadership team also shared several salient quantitative results that were identified during data analysis. This presentation of the data and main themes led to a fruitful and engaging whole-group discussion.

Following the whole-group discussion of these broader themes, participants divided into groups of three to four people each. The leadership team then distributed six case studies of research participants to each group to discuss. Small-group discussions focused on notable aspects of each case, implications for teacher education programs, and implications for future research on intersectionality and CSIs in relation to mathematics teaching and learning. At the conclusion of the session, each small group shared with the whole group highlights from their conversations.

Session 3

We began Session 3 with introductions of new participants. It was also noted that none of the small groups had completed their discussions of the case studies during Session 2, and working group participants demonstrated an interest in continuing this activity. Therefore, the first 30 minutes of Session 3 were spent discussing the case studies in small groups again. During the final hour of the session, a whole-group discussion took place in which participants shared over-arching themes their small groups discussed during the previous two sessions and ideas for future work in this area.

Some of the main themes noted were that many of the pre-service teacher study participants

saw socioeconomic status and mental health as being salient to the learning of mathematics; however, they viewed gender and sexual orientation as irrelevant to mathematics and/or to the mathematics classroom. Mathematics was viewed by most of the study participants as a subject that is "neutral" and therefore participants stated that gender and sexual orientation should not affect the teaching and learning of mathematics. These discussions led to working group participants making connections with previous research they had read, including Rands' (2009) gender-complex education perspective on mathematics education.

Questions to Address in the Future

The discussions held during the 2025 PME-NA Gender and Sexuality Working Group sessions prompted conversations about pre-service teachers' views on the nature of mathematics as being "neutral," which led to many pre-service teachers in the study to claim that a student's gender and sexual orientation would not and should not affect their learning in a mathematics classroom. However, this perspective is not supported by the literature (e.g., Makowski et al., 2025; Suárez et al., 2024). Holding this viewpoint, endorsed by the pre-service teachers who completed the questionnaire, may make them unaware of their own implicit biases (e.g., stereotypes) toward girls and women in mathematics, whose self-concepts and career intentions can then be negatively influenced (Lindner et al., 2022). Further, these same pre-service teachers recognized that when a student has low socioeconomic status or mental health concerns, these identities could directly affect their mathematics learning, which is inconsistent with their beliefs that other student macro-level identities are irrelevant to mathematics learning. These findings have direct implications for teacher education programs.

Based on the discussions held during the 2025 Gender and Sexuality Working Group sessions, the working group leadership team has identified two topics that we plan to address further during future working group sessions. First, we intend to explore more deeply the current research literature on mathematics as a neutral domain and its implications for who feels welcome and included within the field of mathematics and in the mathematics classroom. We also plan to explore more deeply how pre-service teachers' views of mathematics as being gender- and sexuality-neutral affect those who are underrepresented in mathematics and how teacher education programs can help to ameliorate the issue.

Acknowledgments

The working group leadership team would like to acknowledge the pre-service teachers who participated in our study and the 2025 PME-NA attendees who participated in the working group sessions.

asimpson@binghamton.edu

There is a need to understand: 1) what steps PhD programs are currently taking to prepare the next generation of elementary mathematics teacher educator (EMTE) s; 2) what type of preparation and support EMTE require to develop expertise (Goos, 2025); and 3) to generate ideas for PhD programs or for targeted professional development for future or induction EMTE who have had little to no opportunity in their graduate program to develop practices in teaching K-6 mathematics teaching. Thus, we propose a new working group addressing the topic of Developing the Next Generation of Elementary Mathematics Teacher Educators.

Keywords: Mathematics Teacher Educators, Doctoral Education, Elementary School Mathematics Education

Theoretical Background

Existing research has identified significant differences in the work of teaching mathematics and teaching mathematics teaching (Shaughnessy et al., 2016). These differences are especially evident for elementary mathematics teacher educators (EMTE) who are preparing to work with prospective elementary school mathematics teachers. EMTE teaching mathematics teaching are often challenged by the limited theory and resources devoted to teaching mathematics teaching to preservice K-6 teachers. While hypothetical learning trajectories exist for mathematics concept development, such trajectories for pedagogical concept development (Simon, 2018), a central element to designing opportunities for children's mathematics learning, are limited. In addition to the challenge of theory and resources, a more basic challenge lies in the development of MTEs in general (Chapman, 2008). PhD programs are primarily designed to support future faculty as researchers (Reys, 2018), leaving expertise in teaching mathematics teaching to develop through experience (Chauvot, 2008; Wilson, 2006). There is an ongoing need to support the development of MTE as teachers of teaching, a role most PhD students will assume (Shih et al., 2020).

While there is little research insight into the preparation of future MTEs (Chinen & Din, 2024), descriptions and studies of MTEs learning to teach teaching have grown and illustrate the significant challenges novice MTEs face (e.g., Simpson, 2019) as they begin their work with preservice elementary teachers with little to no preparation. Goos (2025) noted that MTE expertise and development is an under researched field particularly given its complexity and the scrutiny of policy makers regarding content and learning opportunities programs provide for future elementary teachers. In addition, the goal of EMTE preparation should reach beyond "surviving" to developing expertise in teaching prospective elementary mathematics teachers. This next generation will be situated to draw from tools prior generations of EMTE have not conceptualized as part of elementary mathematics education including the integration of AI, data science, and computer science. These findings suggest that developing a research agenda

including researchable questions and professional learning opportunities leading to a knowledge base that can inform advocacy and development efforts for the next generation of EMTEs is a critical need.

Title, Topic, and Goals

There is a need to understand: (1) what steps PhD programs are currently taking to prepare the next generation of elementary mathematics teacher educators; (2) what type of preparation and support EMTE require to develop expertise (Goos, 2025); and (3) to generate ideas for PhD programs or for targeted professional development in K-6 mathematics teaching for future or induction EMTE who have had little to no opportunity in their graduate program to develop this practice. Thus, we are proposing a new working group addressing the topic of Developing the Next Generation of Elementary Mathematics Teacher Educators. The proposed working group will be led by the authors, who collectively have taught elementary mathematics methods for over 40 years and have published numerous research articles on activities and outcomes of their elementary methods courses.

Session Organization

Session 1 - What Do Future EMTE Need to Develop Expertise?

Our first session will be focused on introductions (10 minutes) and brainstorming what type of preparation, knowledge bases, experiences, dispositions, and support future or induction EMTE require to develop expertise for teaching prospective elementary mathematics teachers (30 minutes). We will pose the following question for each board, "What preparation (knowledge bases, experiences, dispositions, support) do EMTE require to develop expertise?" Following the group brain writing we will examine each of the different boards (25 minutes) and organize and prioritize ideas (25 minutes) across the four "needs". Our goal by the end of the session is to have a list of prioritized knowledge bases, experiences, dispositions, and supports for future and induction EMTE.

Session 2 - What Are We Currently Doing to Prepare EMTE?

We will begin with a brief presentation (20 minutes) by the organizers addressing the idea of EMTE development and the various pathways faculty members may take in arriving at an elementary preparation position. We will leave space for discussion and comments throughout the presentation (15 minutes). Following the presentation, our goal is to examine our list of prioritized "needs" (20 minutes). Through discussion, we will map these to ideas or activities currently being enacted within participants' PhD programs (35 minutes). This step will provide us a rough idea of how we are currently addressing the needs for future and induction EMTE.

Session 3 - What Can We Be Doing to Prepare EMTE?

Participants will form small groups to work on knowledge bases, experiences, dispositions and supports we have prioritized as important but not currently being addressed within PhD programs. Groups will design ideas to address their chosen priority (35 minutes). Each group will then share their ideas and solicit feedback from the group (35 minutes). The final 20 minutes will be used to discuss next steps for the working group including the submission of a conference grant to support the development of EMTE and creating research and development groups to support the development of a knowledge base and create resources for EMTE developers.

MATHEMATICS EDUCATION RESEARCHERS' INTERDISCIPLINARY COLLABORATIONS WORKING GROUP

William S. Walker, III
Purdue University
wswalker@purdue.edu

Elizabeth Suazo-Flores
University of North Dakota
elizabeth.suazo@und.edu

Interdisciplinary collaborations involving mathematics education researchers (MERs) have become common as an effective way to address large-scale problems and enhance education. While products of such collaborations are documented, how MERs engage in and experience interdisciplinary work remains understudied. This working group will examine theoretical perspectives and disciplinary practices shaping interdisciplinary collaborations involving MERs. Participants will share experiences, map them onto identified practices, analyze theoretical perspectives, and collaboratively develop actionable outcomes. Expected deliverables include an enhanced understanding of practices in interdisciplinary settings, comparative analysis of theoretical frameworks, and designs for future research.

Keywords: Interdisciplinary Research, Mathematics Education Research Practices, Communities of Practice

Mathematics education researchers (MERs) engage in interdisciplinary collaborations to address complex problems and enhance research (Bakker et al., 2021; Bruce et al., 2017; Lannin et al., 2023). Yet, research has noted challenges MERs face when collaborating across disciplines (e.g., Bruce et al., 2017; Darragh, 2022; Goos & Bennison, 2018; Roth, 2020; Suazo-Flores & Walker, in press). This new MER Interdisciplinary Collaboration Working Group will examine two guiding questions: (1) What theoretical perspectives elucidate interdisciplinary collaborations for MERs? and (2) What roles do practices play in empowering and constraining such collaborations?

Disciplines, Practices, and Interdisciplinary Work

Disciplines are communities of practice characterized by specific objects of interest, domains of knowledge, forms of discourse, and methodological approaches (e.g., Pimm, 2009; Roth, 2020; Williams et al., 2016). Disciplinary activities empower and constrain practitioners by supporting the production of disciplinary knowledge while limiting interactions with practitioners from other disciplines (Roth, 2020; Suazo-Flores & Walker, in press; Williams et al., 2016).

As members of a community of practice (Frade et al., 2009; Goos & Bennison, 2018; Wenger, 1998), MERs use disciplinary practices to conduct scholarly work (Suazo-Flores et al., 2021, 2024). Practices are methods or techniques that become tacit, spontaneous, and automatic ways of operating or knowing (Schön, 1983; Wenger, 1998; Williams et al., 2016). We define practices as "established or emergent ways of being, operating, and interacting with others within a community" (Suazo-Flores et al., 2021, p. 24). Being practices refer to how people view themselves and others, including recognition of expertise and roles. Operating practices are agreed upon procedures that acknowledge institutional policies to complete work. Interacting practices relate to negotiating meaning, setting standards for communication, and developing consensus (Suazo-Flores & Walker, 2024). Through a thematic analysis of research literature (Suazo-Flores et al., 2021) and a qualitative content analysis of interview data (Suazo-Flores et

al., 2024), we identified practices in interdisciplinary groups containing at least one MER, organized by the being, operating, and interacting categories (Table 1).

Table 1: Practices in Interdisciplinary Collaborations Identified from Data Analysis

Category	Practice	Short description
Being	View of self	Individual identity, dispositions, and roles in the group
	View of others	Perceptions of disciplinary expertise, roles, and influence
Operating	Common goals	Shared purposes and objectives for collaborative work
	Working together	Processes used to get work done
	Common research interests	Sense of community through research interests
	Understanding institutional support	Recognition of structural and institutional norms
Interacting	Developing ideas	Negotiation of meaning, finding shared meanings
	Building trust and respect	Cultivation of understanding, appreciation of others' points of view

MER Interdisciplinary Collaboration Working Group Goals and Activities

This Working Group will convene a community of practitioners who will collaboratively review theoretical frameworks, examine practices, and develop actionable insights for creating and sustaining productive interdisciplinary collaborations. On Day 1, the organizers will present a brief synthesis of our experiences and research on practices in interdisciplinary collaborations. Participants will share their own experiences in interdisciplinary collaborations, map them onto the identified practices (Table 1), and note any missing practices. On Day 2, participants will engage in discussions of selected articles addressing interdisciplinary collaborations across three categories. First, articles on theories for understanding interdisciplinary work (e.g., boundary crossing, communities of practice, care-driven approach; Akkerman & Bakker, 2011; Bakker et al., 2021; Goos & Bennison, 2018; Noddings, 2010; Williams et al., 2016); second, articles presenting examples of collaborations (e.g., Bruce et al., 2017; Darragh, 2022; Gardner et al., 2021; Goos & Bennison, 2018; Krummheuer et al., 2013; Neihaus & Kaschner, 2023; Norton et al., 2019); and third, articles offering reflections on interdisciplinary work (e.g., Cai et al., 2020; Frade et al., 2009; Steffe, 2010). In small groups, participants will compare Day 1 experiences and examples to theoretical perspectives, describe the role of practices based on the literature, and propose additional perspectives that may enhance understanding of MERs' interdisciplinary work. On Day 3, participants will synthesize insights to develop actionable outcomes by choosing one collaborative project: (1) creating a theoretical framework for understanding practices in interdisciplinary collaborations, (2) using practices to describe MERs' practical engagement in such partnerships, or (3) developing a case study design for investigating an interdisciplinary collaboration involving MERs. Groups will present their work-in-progress and receive feedback. The session will conclude with a discussion of future research directions,

proposals for presentations at future PME-NA conferences, potential publications, and strategies for continued collaboration beyond the conference.

The Disability Studies and Mathematics Education Working Group will be organized around the theme of Critical Disability Studies in Mathematics Education as Asset-Based Pedagogy. Grounded in the understanding that disability is a source of knowledge, innovation, and transformation in mathematics education, participants will engage in self-selected small groups around topics such as: (a) Theoretical Deep Dives into Disability Justice, Disability Critical Race Theory (DisCrit), and Critical Disability Studies; (b) Asset-Based Perspectives on Mathematical Learning and Disability; (c) Accessible and Inclusive Mathematics Classrooms and Educational Design; and (d) Higher Education, including graduate student and early career scholar development. Other topics may also emerge based on participants' interests during the working group. Everyone is welcome!

Keywords: Students with Disabilities; Culture and Asset-Based Pedagogies, Special Education; Equity, Inclusion, and Diversity

"Taking up space as a disabled person is always revolutionary" (Ho, 2020, p. 115).

History

Kai Rands and James Sheldon created this working group, which met formally from 2016–2018. During these early meetings, members discussed theoretical perspectives within their work, described current projects, and raised critical issues. This core group of faculty, graduate students, disability activists, and classroom teachers also included Amber Candela, Jessica Hunt, Rachel Lambert, Katie Lewis, Paulo Tan, and Cathery Yeh. The working group reconvened in 2022 and has met each year since. Members collaborate to conduct research, write grants, present at research and practitioner conferences, and produce manuscripts.

Goals and Effort Toward These Goals

As we prepare for PME-NA 48, we center the perspectives developed by disabled people that have been often overlooked in mathematics education (Lambert & Tan, 2020), even within calls for equity. Because mathematics classrooms are often used as tools for marginalization, we also use critical theories that have an asset-based stance within their tenets such as Disability Studies in Education, CRT, and DisCrit to offer a justice-oriented vision of mathematics education.

PME-NA 48 marks the eighth meeting of this working group. Therefore, our goals encompass the continuation of past work as well as the development of new work:

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

- Create more accessible space centering disability and mathematics education;
- Anchor our work in the 10 principles of Disability Justice (Sins Invalid, 2019);
- Generate interdisciplinary and cross-institutional collaborations; and
- Leverage the group's collective wisdom to (re)imagine solutions to persistent problems.

Our strategies to meet these goals include:

- Providing a hybrid option for the working group;
- Centering the voice and work of disabled scholars and educators;
- Designing spaces that prioritize focused, small-group work; and
- Identifying small-group leaders to facilitate the cross-pollination of ideas.

Theoretical Background

We adopt disability as asset-based pedagogy in which disabled people—researchers, practitioners, and students—offer a powerful transformational, epistemic lens. This stance draws on feminist philosopher Garland-Thompson's (2011) construct of the "productive power of misfitting;" Being disabled in a world that is not made for us illuminates structural aspects of the environment that others miss. The acts of adaptation that disabled people do to navigate a world not built for them reveal alternative ways of knowing and being.

We adopt this asset-based stance to disrupt ableism through Disability Studies in Education and Critical Special Education (Connor et al., 2008; Connor, 2019; Lewis & Mason, 2025), interrogating how ideologies of "ability" and "normalcy" (Annamma et al., 2013; Siebers, 2008) are constructed within mathematics education (Dolmage, 2017; Price, 2021; Westby, 2021).To enact this pedagogy, we draw upon the 10 principles for disability justice created by Patty Berne and others (Sins Invalid, 2019), including intersectionality, recognizing wholeness, and collective liberation. This framework situates ableism within intersecting systems. We emphasize the inherent assets of disabled people, including unique mathematical ideas, pedagogies, perspectives, and solutions. We challenge deficit narratives to unsettle entrenched structures of ableism in mathematics education (Lewis & Lynn, 2018; Yeh, 2023).

Plan for Active Engagement and Working Group Organization

In response to the growing size and diversity of our working group members, and with respect to the interests that surfaced in last year's group, we have designed a structured, flexible three-session sequence. Group members have choice in how and with which topics they engage. Small groups have autonomy to define what "meaningful outcomes" mean for their members and a timeline for achieving them. These strategies promote active and purposeful engagement.

Session 1: Community, Connections, and Co-Designing

This session orients people to the working group. We start with introductions and access needs, followed by an update about the group's accomplishments, sharing the goals of the group, and frame of disability as asset-based pedagogy as educational design and research. We then introduce small-group topics and identify additional small groups that may arise. Small-group topics include the integration of asset-based pedagogy as educational design and research, but are not limited to: (1) conference accessibility (2022–2026); (2) engaging graduate students and early career scholars (2024–2026); (3) halting state "science of math" policy (e.g., addressing the "Science of Math" website; growing out of work from 2022); (4) building accessible classrooms (2025–2026); and (5) theoretical deep dives into Disability Justice, DisCrit, and Critical Disability Studies (2024–2026). This session concludes with small-groups articulating goals.

Session 2: Generating and Planning

This session will be primarily in small groups. We briefly (re)introduce people, share access needs, and our framing of disability as asset-based pedagogy in educational design and research (15 min). Groups identify actions toward meeting goals from the first session. We transition into small groups identified in Session 1. We conclude by coming back and sharing.

Session 3: Articulating Next Steps

We begin in groups, reconvene as a whole group to share, and conclude by articulating plans for support beyond the conference. This includes ongoing collaboration and advocacy through both whole-group and subgroup venues (e.g., a 2025 subgroup already collaborating via Discord, where a conference paper has been accepted and new members invited).

In continuing with past working groups on research at the intersections of Disability Studies and Mathematics Education, this working group met at PME-NA 47 to share new developments from group members, form new connections, and advance shared goals. Folks engaged in self-selected small groups around these topics: (a) Research Colloquium About Conference Accessibility, (b) Engaging Graduate Students and Early Career Scholars in this Network, (c) Building Accessible Classrooms, (d) Halting State Level "Science of Math" Policy; (e) Book Group .

Keywords: Students with Disabilities; Special Education; Disability Studies; Equity, Inclusion, and Diversity

History

Kai Rands and James Sheldon conceptualized and convened this working group, which met formally from 2016–2018, although other informal meetings occurred before and after these dates. In these early sessions, group members explored different theoretical perspectives within their work, shared ongoing projects, and raised critical issues. This collective of faculty, graduate students, disability activists, and classroom teachers included: Amber Candela, Jessica Hunt, Rachel Lambert, Katie Lewis, Paulo Tan, and Cathery Yeh. The working group convened in 2022 and has met yearly at PME-NA, collaborating on research, grants writing manuscripts and book publications, and engaging with the Mathematics Education, Special Education, and disability communities.

Work at PME-NA 47

Across the three sessions at PME-NA 47, approximately 30 people engaged in our hybrid working group. This hybrid approach expanded access to participate and engage for those who would have otherwise been excluded from an in-person-only space. The decision to adopt a hybrid model emerged from group members' concerns about COVID-19, travel, in-town transportation, and the challenges caregivers and disabled scholars and educators face when being away from home for extended periods. Our group reflected on how hybrid access fostered greater inclusivity, particularly for disabled, immunocompromised, and otherwise marginalized scholars (Doran et al., 2024; Joo, 2021). Hybrid access also enabled organizers and participants to build relationships and collaborations before, during, and after the conference. Across three days, we built community, met in small groups, and developed plans extending beyond the

Leatham, K. R., Peterson, B. E., Siebert, D. K., & Teuscher, D. (Eds.). (2026). *Proceedings of the forty-eighth annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Brigham Young University. https://doi.org/10.51272/pmena.48.2026

conference itself. We consciously took steps to structure communication across modalities, demonstrating that collaborative, generative work can thrive in hybrid environments. We created a set of shared documents to capture meeting notes, conversations, and ideas.

Day 1: Community, Accomplishments, Small Groups

Our group began with introductions and an explicit invitation to share access needs, a practice emphasized by activists and scholars (e.g., Reinholz & Ridgway, 2021; Sins Invalid, 2019). Participants named their roles, pronouns, and needs. For example, "I am [name], and I am at [university]. My pronouns are she, her, hers, and it's important that I am able to get up and stretch; I need to take breaks periodically," or, "My access needs are being met through having the virtual environment." These openings foster camaraderie as members recognize shared needs and collectively consider how to meet them. These introductions also create opportunities to connect around professional roles or interests, where surfacing how taken-for-granted professional norms can unintentionally reproduce ableism. One of the common access needs involved attending in "nonstandard" ways; for example, for many people, attending virtually was an access need that was being met by this group but not at the conference more generally.

During these introductions, we documented names and contact information in a shared electronic file to support connections during and after the conference. One commonly expressed need was the availability of a virtual participation option. Throughout the session, organizers regularly checked that access needs were being met and that communication across both modalities remained smooth and inclusive. One purposeful action to improve access and inclusion was to invite all in-person attendees to join the same Zoom call as the virtual attendees. This move facilitated more equitable participation for everyone. This intentional structuring affirmed virtual participants as full contributing members of the community and prompted critical reflection on the implicit ableism that virtual participation is often viewed. Several members noted disappointment that similarly accessible structures were not available across the broader conference, limiting participation for many marginalized scholars. We updated attendees on the progress the group had made since the last meeting. Accomplishments included: (1) Meetings with PME-NA and other conference organizers to address issues of conference accessibility in which update was shared that, AMTE and RUME were offering a virtual option for their upcoming conferences, led by Alison Mirin and Paulo Tan and coordinating with Zareen Aga, Ayman Aljarrah, and Sabrina Zarza. (2) Update on book proposal on disability as driver of change, led by Cathery Yeh, Katie Lewis, and Paulo Tan. (4) A manuscript which employs Discourse Analysis to make sense of the "Science of Math" website led by Erica Mason and Katie Rupe is currently under review for publication.

Five small groups formed and set their own agendas for subsequent meetings: (a) a research colloquium on conference accessibility (b) engaging graduate students and early career scholars in this network; (c) building accessible classrooms, and (d) halting state level "Science of Math" Policy.

Day 2: Small Group Work

Our next meeting afforded the opportunity to enact the value that access is a collective responsibility, thereby moving toward a collaborative actualization of Disability Justice (Piepzna-Samarasinha, 2019). One small concrete example of this occurred as people arrived at the session. During Day 1, a group member explained how dimmed lighting improved access for them. This need was preemptively included on Day 2 as well without needing to be requested again. They did this because increasing access meant we all had a greater understanding of each other's access needs and were thus all able to honor those needs and engage in deeper work. In-

person attendees also continued the practice of joining the Zoom meeting and encouraging new attendees to also join the Zoom meeting.

With several new attendees, we began by (re)introducing ourselves and conducting another access check-in. We then worked in small groups for the majority of the session before reconvening as a whole group to share and brainstorm next steps.

Day 3: Small Group Work and Articulating Next Steps

On our final day we dedicated the majority of the time to small group work. Each small group shared aloud to the whole group. Below are the key takeaways from each group.

Research colloquium about conference accessibility. The small group highlighted that conference accessibility must move toward concrete, operationalized change that broadens participation. Their central aim is to develop actionable recommendations and a research colloquium that reframes accessibility as a collective responsibility that includes virtual options, intentional norm-setting around access needs, inclusive networking structures, and responsiveness to accommodation requests without debate. The group discussed different math education organization conferences and examining lessons learned from their virtual or hybrid conferences. The group seeks to produce tangible demands, a formal report, and sustained scholarship that aligns conference practices to expand access for disabled, caregiving, queer/trans, and financially constrained scholars.

Engaging graduate students and early career scholars in this network. This group centered on building intellectual community and infrastructure for graduate students working at the intersection of disability studies and mathematics education. The group discussed developing shared grounding in key literature to establish an academic lineage and collective scholarly identity, while fostering collaboration through shared research interests, writing partnerships, and contact networks. A major outcome is the plan to launch an open-access, graduate student–led journal (with Paulo Tan as Editor-in-Chief and faculty support) and potentially housed in an existing digital repository. The journal will welcome diverse formats (completed research, works in progress, theoretical pieces, and multimodal submissions such as audio or video) and will be supported by an editorial board, a reviewer pool, and a defined review process. The group also discussed sustaining the community through regular meetings, networking to identify contributors and collaborators, and exploring models such as workshops (e.g., TODOS) that provide structured feedback for emerging scholars.

Building accessible classrooms. This small group focused on critically examining the implementation of *Building Thinking Classrooms* (BTC) to ensure that practices are accessible, equitable, and grounded in social justice. Members emphasized understanding the principles behind BTC, rather than treating it as a checklist, and highlighted the ways uncritical adoption can harm marginalized students, including disabled, Black, and Brown students. The group discussed producing publications that make these insights accessible to others with key priorities centering intersectionality, acknowledging historical inequities in classroom practices, and framing accessibility as a collective responsibility. Actionable steps involve developing article outlines, coordinating collaborative writing, maintaining shared resources via a Google Drive and Discord, and ensuring ongoing discussion of equity, inclusion, and accessibility in both research and classroom practice. This work has resulted in an accepted presentation for TODOS 2026.

Halting state level "Science of Math" policy. The group focused on responding to state-level "Science of Math" (SOM) policies, highlighting that SOM promotes a narrow, misleading, and one-size-fits-all approach to mathematics education that ignores the complexity of learners,

classrooms, and research evidence. Key concerns raised included selective citation practices and the elevation of certain pedagogical methods while marginalizing other approaches. Action steps include developing op-eds, conducting state-by-state analyses, leveraging existing initiatives, and creating visual summaries of research to clarify what constitutes robust, equitable, and relevant math research. The overarching goal is to provide evidence-based, inclusive alternative publications and formats that are more accessible and with broader reach.

Progress Since PME-NA 47

Small groups have continued work on several collaborative projects. At this time, there are no updates to report about the progress of conference-generated initiatives; several ongoing projects have continued to progress. (1) Erica Mason and Katie Lewis have an upcoming virtual AERA session "Unpacking Critical Special Education", (2) working group members presented together for a symposium at MES Chile, and (3) AMTE offered a virtual option for their winter 2026 conference and TODOS is working towards virtual options and improved accessibility for the Summer 2026 Conference.

Actions to Include Participants

To include as many people as possible, we implemented several intentional strategies. First, by offering a hybrid option for our working group, we signaled to our colleagues and in-person conference attendees that we prioritized enacting our values of inclusivity and access. We deliberately employed best practices to ensure that those attending virtually could fully participate and were not viewed as "lesser" or secondary to in-person attendees. Further, when people joined on the second or third days, we took care to pause to introduce the newcomers and orient them to the ongoing work. Beyond the conference, we maintained the Google Group to support continued connection, community building and recruitment, positioning PME-NA as a focal site for those interested in critically engaging with mathematics education and disability.

Questions to Address in the Future

Critical questions that our group will continue to address include:

- How can we define "critical disability studies in mathematics education" in ways that center accessibility, equity, and social justice?
- How does "critical disability studies" intersect with "critical special education", and how can we leverage insights and/or disrupt traditional practices from both to inform research and practice?
- As mathematics educators, how might we collaborate meaningfully with scholars and practitioners from other disciplines, including special education, to advance inclusive and humanizing practices?
- How strategies can this group employ to promote activism and advocacy within conferences, institutions, and broader mathematics education networks?
- What kinds of conversations about disability and mathematics education are happening in local, regional, and international contexts and how can those inform the work of this group?
- What additional approaches are needed to address disability with race, gender, and other identities in mathematics education?

- How can we meaningfully engage and mentor doctoral students and early career scholars, building a community that supports ongoing critical scholarship within and beyond mathematics education?
- How can we support novice and experienced researchers in collaborating and learning with disabled students, educators, and scholars in ways that are ethical, inclusive and rigorous?
- What role can this working group play in expanding conference accessibility and inclusive practices particularly through partnerships by aligning with organizations' commitments to equity and inclusivity?
- How can we ensure our work remains relevant and impactful in the face of shifting political and institutional pressures around diversity, equity, inclusion, and access?
